She had not been under treatment in England; but for some years past had visited German baths under local medical advice, and her German doctor, who was at the moment in England, accompanied her at her next visit to me. I told him my views, with which he agreed, and before taking leave he did not fail to impress on me the absolute necessity for a further, and immediate, course of (German) baths! I learned later that before her marriage her husband had taken her to consult Sir William (then Dr.) Gowers, in view of their projected marriage. Sir William Gowers explained to him the nature of the disease (syringomyelia) and told him to "get out of his head" any idea of taking the proposed step. The sequel was "the old, old story,"—they walked out of the consulting-room and thence, almost immediately, into the church.

Since that time the case has presented a steady, but astonishingly slow downward progress. The breathing is shallow, "costal respiration" is hardly perceptible. The diaphragm is acting far below its normal strength, but in forced respiration the sterno-mastoid and trapezius are still acting. Wrist flexion and extension and some pronation are still weakly present, but the claw-like hand ("main-en-griffe") is fully established. There is now very notable loss of power in the legs, and a quarter of an hour's shopping on the arm of a companion is all that she can accomplish. In a sitting position every voluntary movement of the leg can be carried out, although feebly and with effort, but in walking or standing balance is insecure and at times almost impossible. There is exaggerated knee-jerk on the left side, electrical reactions weak; can distinguish "hot" and "cold." The eyes are healthy, but about 20 years ago diplopia was present. Both external recti muscles were affected and the right inferior oblique, but the diplopia was not constant, and eventually disappeared under the use of glasses for near work, to take off the strain on accommodation. No articular troubles.

*Treatment.*—As the patient's general health has been excellent during the whole period under review, I have relied throughout on the triple agencies of electricity, massage, and movement. Three times yearly for 12 consecutive days the case has undergone this treatment, systematically and laboriously carried out. Uphill work for both patient and practitioner—the latter ever conscious that, successful though his delaying tactics may be, he must ultimately and inevitably prove to be the "player of a losing game."

## ROYAL SOCIETY OF MEDICINE:
### GENERAL MEETING OF FELLOWS.

A general meeting of Fellows was held on Jan. 25th, with Sir **StClair Thomson**, President, in the chair, when Lord **Dawson** opened a discussion on

### Hyperpiesis.

He said that it was natural in such a discussion to refer to Sir Clifford Allbutt, the great master who still inspired our thoughts on this subject. He had preferred the term "supertension" to "hypertension," and this term the speaker would use. The choice of "hyperpiesis" was preferable for discussion to that of "hyperpiesia" because the key to the disease and hope of alleviating it lay in the study of its beginnings. Supertension was not a disease, but passed gradually and without any sharp dividing line into certain disease conditions, better considered under their own proper headings.

### *Association of Supertension with Over-responsive Vasomotor System.*

He believed that there was a group of people who had an over-responsive vasomotor system just as others were liable to nervous dyspepsia and diarrhœa; it was part of their make-up. They were liable to transitory supertension under physical or psychical stress, some under the former alone, but the majority under psychic strain, particularly ambition. It might be a family trait. The link between the higher centres and the vasomotor centre was too intimate, so that the latter responded to every disturbance. He took, for example, three apparently healthy, happy school-boys. The first had a pressure of 125/60 recumbent which rose to 162/65 after running up 72 stairs two at a time. This was no more than one would expect from a boy slightly agitated at going to school for the first time, and it returned to the former reading after six minutes' rest. The second boy gave readings of 110/65 and 135/70, but the third had a recumbency pressure of 135/70, which went up to 170/85 after effort and took 20 minutes to return to normal. He was a potential hyperpiesic. What was in store for him depended on his circumstances, how engrained his vasomotor response was, his temperament, whether placid or over-anxious, whether he became a slave to anticipation, his employment, his social life, whether congenial or discordant, his physical habit, and his family tendencies. He might keep within the normal till middle age. Other examples of hyperpiesis were found in a series of 580 Toronto undergraduates, 10 per cent. of whom had a pressure over 140; in Alvarez's series of 1500 undergraduates, 20 per cent. of whom were over 140, and in a series of 650 London school-children, aged 10–17, 8 per cent. of whom were higher than 130. Some of these showed signs of cardiac stress; a little displacement of the apex, an enlargement to X rays, some accentuation of the second aortic sound, and a left-sided preponderance. There was evidence that supertension did exist among the young, and though in many it might be a passing phase it was not so with all. The condition was a reaction to modern civilisation. Dr. Strickland Goodall had found that the most frequent antecedent of a high blood pressure in cases under 40 years of age was scarlatina, but in Lord Dawson's opinion there was too strong a bias in favour of infection and not enough attention was paid to the soil. It was not likely that most of these healthy young people were the victims of infective processes. Frost had investigated some adult subjects of mental stress and anxiety and found a resting pressure of 148 with rise to 220 after effort; the same case examined on another day when the stress was absent gave a perfectly normal reading of 118–144. No individual with normal responsiveness of the vasomotor centre would show such a change in reading. In the next stage of the condition the rest pressure went to a higher level and the patient might complain of headaches or throbbings. The diastolic reading was of the greater importance; if it were not higher than 100 and there was no arterio-sclerosis a moderate systolic rise was not serious. As an example of a fixed supertension in youth he cited a girl of 23 who looked and felt healthy and had no disability save easy fatigue after a full day's work and some breathlessness after heavy exercise, with occasional headaches. She had had scarlet fever. Her resting pressure remained for several years 250/150, going to 280/150 after effort, and a month's careful treatment to reduce the figures only resulted in their return to the original reading after the first ten minutes' walk. Her younger sister had a rest-reading of 160/100. Her heart was slightly enlarged and her radials too palpable. Histologically, her kidney showed a marked pure hypertrophy of the media with early atrophy of the tubules. In some of the smaller vessels there was some hyaline thickening of the intima and splitting of the elastic tissue and focal deposits of fat, but these changes were slight. Hyperplastic sclerosis was probably not a factor in the early stages of hyperpiesis, though it played an increasing part later. It showed a marked selection for the vessels of the kidney, pancreas, and spleen, and developed in the course of hyperpiesis, which was apt to be followed by clinical arteriosclerosis, although the latter condition was not associated with hyperpiesis in half the cases. The two things might hunt in couples when hyperpiesis had reached a certain stage. Comparing the above early case of hyperpiesis and a case at a later stage, Lord Dawson pointed out that the thickening of the media was marked and the intimal change slight in the early case. At a later stage the thickening of the media was less apparent and the intimal change more apparent. It looked as if at a later stage the muscular tissue of the thick media might be replaced by fibrous tissue. The intimal change, though bearing no necessary causal relationship to hyperpiesis in the initial stages, yet gave the kidney large control in the later stage. The patches of atrophic tubules were due to failing blood-supply and their extension probably went hand in hand with hyperplastic sclerosis. These areas of atrophy and replacement fibrosis might extend with time, reduce the amount of functioning tissue and so lead to more cardiac hypertrophy. They might extend so as to involve glomeruli in such numbers as to produce an ischæmic nephritis—hence, perhaps, the resemblance of certain cases of advanced hyperpiesis to interstitial nephritis. There had been 4 of such out of 23 cases of high blood pressure recently reported by Dr. John Parkinson in his paper on heart failure with normal rhythm. He wished to emphasise that in its beginnings hyperpiesis had a functional origin, although the majority of cases showed themselves in later life associated with eclampsia and with the blubber type of obesity, suggesting warped metabolism. The chemistry of the condition was very difficult and liable to error. Investigation had shown no definite relation between it and the taking of meat, alcohol, or tobacco. It was a condition of over-excitability of the vaso-constrictor centre. In conclusion, said Lord Dawson, what were the beginnings and what were the stages in the evolution of the condition? The origins were several; the anatomical course was the same. Could, and did, hyperpiesis have an origin in exaggerated function—in an excessive vaso-constrictor responsiveness? If so, was hypertrophy of media and heart the earliest change? Or did hyperpiesis take origin in a previous infection? If so, was the next stage thickening and degeneration of the intima? When the condition occurred in middle life was the first stage infection or perverted metabolism? If so, was the resultant hyperpiesis the result first of vaso-constriction or of intimal degeneration? These were important questions from the point of view of early and preventive treatment.

Prof. F. R. FRASER said that the mean arterial pressure depended on the output of the heart and the peripheral resistance. He proposed to deal only with factors influencing the latter. In health it was so regulated by elaborated nervous reflex mechanisms that an adequate supply of blood was maintained to all the tissues. The vasomotor centre in the medulla was of principal importance. An adequate supply to the centre caused a rise of general arterial pressure through constriction of the arterioles, particularly in the splanchnic area. The centre was also stimulated by afferent peripheral stimuli such as those of pain. The higher parts of the cerebrum could also effect general arteriole constriction, as in sudden emotional states and the state of anticipation of sudden exertion. The injection of adrenalin could produce this effect, but to what extent the adrenal bodies were responsible in emotional states was still undecided. Chemical substances in the circulation could also produce a general arterial rise. Constriction of the arterioles and structural changes in the blood increasing the resistance to flow, as in hyperplastic sclerosis or erythrocythæmia, would have a similar effect. In such cases the raised blood pressure was a symptom of the more fundamental disease processes. A solution of the relationships between raised arterial pressure and degenerative changes in the arteries and renal disease would throw light on the whole problem. The possible causes for hyperpiesis appeared to be: (1) Disturbance of the vasomotor centre. (2) Influences at the centre from the higher parts of the brain or the periphery. The therapeutic success of rest cures and of education in hygiene favoured the existence of such a relationship, although it was difficult to see how emotional states could produce a persistent rise of pressure. Possibly there might be some adaptation similar to that of conditioned reflexes. (3) Circulating chemical bodies including internal secretions. This was supported by the number of cases arising about the menopause and those in adolescence that disappeared in adult life, and also by the satisfactory therapeutic results of restricted diet and restricted indulgence in alcohol and tobacco. (4) Unrecognised arterial or renal disease in early stages. It was probable that the persistently raised pressure in the group of cases labelled "hyperpiesis" was the result of a number of causes. In every early case careful note should be made of hereditary factors, constitutional make-up, exposure to mental and physical stresses, over-indulgence or unbalanced dietary, infections, and evidence of disturbances of internal secretion. He pleaded for more extended use of the sphygmomanometer, the diastolic pressure being the better guide to peripheral resistance.

Dr. F. PARKES WEBER denied that hyperpiesia could be an outcome of the stress of modern life. Prof. E. H. Starling had shown that the normal brain needed a well-maintained blood pressure, and that if there were any danger of the blood pressure in the vasomotor centre and brain becoming insufficient, the blood pressure of the whole body would be raised. Some persons who had led a very active life began to react to its stress at the age of about 50 by increasing blood pressure. This, he thought, was because the cerebral circulation became defective owing to changes in the arterioles, and because the nervous centres became blunted in some way and needed a higher blood pressure in order to enable them to perform the work demanded of them. The type of individuals that reacted to the stress of civilised life by increasing their blood pressure, while others remained at the prime of their usefulness, were not the constitutional neurasthenics and psychasthenics, whose safety-valve was their nervous system. Nor were they the chronic dyspeptics and visceroptotics whose gastro-intestinal system reacted to any stress with pain. They were people who have habitually taken more food, with or without excess of alcohol or tobacco, than they should have. They usually belonged to families with a tendency to high blood pressure. They did not reduce their food intake after puberty, but rather increased it. This set up a kind of vicious circle; for too much food produced a toxic condition, which affected the circulation of the brain. The resulting distress caused them to enrich their diet. The hyperpiesia of early life was much graver, for the constitutional factors outweighed all other. To try to produce an artificial low blood pressure by applying X rays to the suprarenal capsules, or by excising part of one of them, was very dangerous. He could not agree with the association of hyperpiesia with a large erythrocyte count.

Dr. J. A. RYLE stated that the predominant factor in high blood pressure conditions was a diathesis. He summarised the results of his analysis of 50 patients whose systolic and diastolic pressures were over 170 and 100 mm. respectively. Sixty-two per cent. were robust and stout; these he called the hypersthenic type. They possessed, as far as their alimentary system was concerned, a hypersthenic diathesis; their chest dimensions were large and the tone of their digestive muscles good. American observations on students showed that 10 per cent. of this type had hyperchlorhydria. Their output of work and their appetites were large. If they formed habits of excessive eating, working, or worrying their blood pressure would rise. These had rarely seen a doctor before for anything serious, and came when their complaint was still recent. High blood pressure in these was an exaggeration of their physical characteristics. 16 per cent. had poor physique. Their symptoms had appeared early in life, and they had suffered from alimentary trouble, pulmonary tuberculosis, and other chronic diseases. This type of hyperpiesia was entirely different from the hypersthenic type. 4 per cent. were nervous subjects, and their condition had inhibited the tendency. Two other groups were familiar: (1) where the menopause helped the constitutional disposition, (2) youthful cases which were exceptional. He said that we should probably obtain better results from studying the soil on which the condition flourished than by laboratory methods.

Dr. **DOROTHY HARE** drew attention to the fact that there might be considerable variations in blood pressure readings in any individual under uniform conditions. There might be a difference of 20 mm. in consecutive readings at one sitting. Her figures were drawn from a series of normal pregnant women seen at intervals of about a month. The conditions of examination were kept as uniform as possible, the patients lying down for at least 20 minutes before a reading was taken. The first reading was always discarded and then three consecutive readings taken by the same observers on the same instrument. The two arms were measured simultaneously and might show a difference of 10–20 mm. pressure, the right being higher than the left in 83 per cent.; 31 per cent. of the cases showed variations of more than 10 mm. in consecutive sittings.

Sir **JOHN BROADBENT** said that it might be taken for granted that some families had a tendency to high blood pressure and some to low. There was no high blood pressure without some degree of peripheral resistance. It was unreasonable to assume that high blood pressure was necessarily due to the nitrogenous excitatives that accompanied kidney trouble, for this was often absent. There must be some common cause. High blood pressure might be responsible for kidney trouble. Even if the vasomotor system were over-excitable there must be some toxin to excite it; adrenalin and thyroid would cause hyperpiesis, but there was no evidence of the hypertrophy of either of these glands in the majority of cases. High blood pressure and renal disease had many symptoms in common, but death in coma and convulsions was very rare in the former. It was impossible to state what the toxic substance was, but we should look less to the kidney for the cause of hyperpiesis and more to deficient metabolism by the liver. The French had given the name "uræmic moiety" to an unknown constituent that combined with excess of nitrogen in uræmia; this moiety might have some bearing on hyperpiesis.

Dr. **HENRY ELLIS** said that it was important to remember that the two types described differed in chemical composition. The first type—the majority—had always an increase of phosphoric acid in the urine, the ratio of combined ammonia and free phosphoric acid being level, and in these the toxic element could always be ruled out. In the second group the ratio was 3 : 1, and in all these cases there was a toxic element. If hydrochloric or other acid were administered to the first group the blood pressure rose markedly; in one case six doses of acid raised it from 140 to 250. This was due to a deficiency of the capacity of eliminating acids. High blood pressure in mature people was coördinated with increase of the acid ratio. Usually an intestinal toxæmia could be demonstrated, due to erroneous absorption of amino-acids which were eliminated by the kidneys. The rise of pressure was necessitated by the deficiency of elimination. Once raised it could not easily be altered, for sudden drop again would alter the inter-cellular equilibrium. It would not be possible to differentiate these cases until the urine was systematically examined. It was really a blood condition; possibly the viscosity of the blood was altered.

Dr. **J. C. BRAMWELL** agreed that the diastolic pressure was very important; a rise in the diastolic pressure raised the mean pressure and made the arterial wall much less distensible, which entailed a rise in the systolic pressure if the heart was to maintain its output. It also limited the oxygen intake of the body; even a great increase in the pulse-rate would only allow of very mild exertion. There was a compensatory modification of the cardiac mechanism, a prolongation of the ejection phase of systole, so that some of the blood discharged into the aorta had time to escape to the periphery before the heart attempted to discharge the rest of its contents. The sphygmograph record was of value in prognosis; so long as the systole was prolonged the muscle must be fairly satisfactory; when the record became more normal in appearance the prognosis was less good.

Dr. **HALLS DALLY** said that the same term was often used by different writers in a different sense and he was concerned with classification. Hyperpiesis was a rise in arterial pressure from any cause whatever, whether temporary or permanent. Ultimately the problem rested on physics. In physics there were only two causes for increased pressure—increased force and increased load. He suggested dividing hyperpiesis into three: (1) Hyperdynamia, (*a*) primary, in cases which necessitated an augmentation of the driving force of the heart and great vessels; (*b*) secondary, compensatory to (2) hyperachthia, which might be (*a*) primary, an increase in tone and thickening of the vessel walls associated with hypertonia, or (*b*) secondary, an increase of tonic contraction in response to hyperdynamia. (3) Hyperpiesia. This scheme could be adapted to low blood pressure by substituting "hypo" for "hyper." He wished to register a protest against the term "hypertension."

Dr. **C. O. HAWTHORNE** suggested that the term "blood pressure" should be done away with altogether and the term "sphygmomanometer reading" substituted. The fact was the reading; whether that meant blood pressure or not was still uncertain. He had noticed that the blue hands and chilblains of young women so often seen in out-patients were invariably associated with a high reading. He was quite sure that high readings in early life did not always mean a progressive condition.

Dr. **KINGSTON BARTON** said that he was obsessed by the idea that all cases of persistent high pressure could be reduced to some disease in the kidney. The prevailing tendency was to treat disease without knowing what health was. It was ridiculous to send cases of high blood pressure away as having "no disease" or "no cause." Fifty per cent. of the post-mortems done in London revealed kidney disease, but the assigned cause of death was "heart failure" or "cerebral hæmorrhage." They were told there was no kidney disease because there was no albuminuria; but the kidney could not be said to be sound before the heart had been X rayed and the blood-urea estimated. Hyperpiesia was a physiological safeguard and patients could not live without it.

## SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

AT a meeting of this Section held on Jan. 22nd, with Dr. E. W. GOODALL in the chair, Prof. E. W. HOPE read a paper on the

### *Influence of the Universities on the Advancement of Public Health.*

He pointed out that in the pioneer work of early nineteenth century hygienists the universities had no direct share. Revelations at inquiries into the condition of the people, the fear of cholera, and perhaps the publications of the Registrar-General, had excited the interest of educated men. The citizens of Liverpool had appealed to Huxley for advice, and through his recommendation had obtained a classical report by Burdon-Sanderson and Parkes. Sufficient interest had been excited by the beginning of the '70's of the last century to secure the establishment in several universities of diplomas in State medicine. The first to move had been the University of Dublin, although certain aspects of preventive medicine had been dealt with in the Scottish universities for many years previously. Describing the later developments of university teaching, Prof. Hope emphasised the importance of universities, not only for the training of undergraduate and graduate students but as centres to which all members of the community could look for guidance and special instruction.

The paper was discussed by Sir GEORGE BUCHANAN, Sir WILLIAM MACPHERSON, Dr. MAJOR GREENWOOD, Dr. G. C. TROTTER, and the CHAIRMAN.

## MEDICAL SOCIETY OF LONDON.

### MANIPULATIVE TREATMENT IN MEDICINE AND SURGERY.

AT a meeting of this Society, held on Jan. 25th, with Sir HOLBURT J. WARING, the President, in the chair, a discussion on Manipulative Treatment in Medicine and Surgery was opened by Mr. W. R. BRISTOW and Mr. R. C. ELMSLIE, whose contributions appear in full on another page.

*Discussion.*

Dr. H. A. DES VŒUX considered that the opening papers would have given the general practitioner much which would be useful to him, as he had not been taught anything at hospital concerning the cases which required manipulative treatment. The ordinary doctor seemed to be afraid of them. He agreed with Mr. Elmslie when he said there were 12 separate conditions of the knee-joint and that they were often very difficult to diagnose. And there was a medical side to the question of manipulative treatment, mainly in the matter of referred pains. Patients who complained that they had neuritis of a limb, which had been existing for months, or a year, were often found to have stiffness and adhesions but no neuritis, and careful manipulation of the joint would cure the pain in many instances. And in these cases cross-examination would bring to light an injury which had been forgotten. He mentioned some cases of the kind in his experience. He agreed with the openers that the main blame for the present condition of affairs rested with the lack of teaching concerning these cases at the hospital; it was because of this lack that the profession found itself on the defensive to-day on this subject.

Mr. T. H. OPENSHAW endorsed all that Mr. Bristow and Mr. Elmslie had said. If a man with a disability went to a bonesetter for treatment and was made worse by him it was the last thing the patient spoke about, but if he had been to members of the profession and then went to a bonesetter the latter never ceased to talk about it. The first thing the bonesetter did was to approach the people who wrote for the lay press. Some of these irregular practitioners seemed to be really innocent believers in their own ability. The newspaper crusade constituted a terrible handicap to the regular practitioner, as also was the holding of exhibitions on stages in various parts of the country. A case of the kind was that of a girl who 20 years ago came to the speaker with a paralytic hip-joint; her hip was constantly coming out of the joint at awkward times. She was brought to him at the orthopædic department of his hospital, and he put her into a splint and in three months the hip ceased to come out when she did not wish it to. After that he did not see her again. She was later secured by a bonesetter and paraded about the country, he paying her 5s. a night for exhibition. She walked on to the stage with her splint, the bonesetter called a doctor out from among the audience to certify that the hip was out, he then threw away the walking apparatus, manipulated the hip, the girl helped him by giving a wrench, the hip went in; she was again examined by the doctor, who announced his finding, and the girl walked off the stage unaided. He believed the demonstration was still proceeding.

Mr. ARTHUR EDMUNDS denied that the general surgeons in large hospitals did not take an interest in bone and joint cases and teach students concerning them. It must be remembered that each surgeon had only a limited number of beds, and many cases which would constitute excellent teaching material could not be accommodated. His teacher, Sir Watson Cheyne, did not omit the teaching of manipulation in bone and joint cases; indeed, it could be said that he was keen on it in the proper kinds of cases.

Dr. W. W. STOCKER said he had seen a well-known bonesetter at work, and if patients of his desired to go to a bonesetter he did not try to dissuade them. But he had never, in a long practice, seen a success achieved by a bonesetter on any of his (the speaker's) patients. He had found that it was of no use to argue with patients on this matter, as they were hypnotised by the press.

Dr. J. P. TRAYLEN spoke of the importance of getting from the patient a history of fairly recent injury, as this would often make clear an apparently obscure and difficult case.

Dr. P. B. SPURGIN said he thought the present difficulty in the matter under discussion was due to the great increase in medical knowledge in the last 20 years. In the old days apparently severe lesions were successfully treated by manipulative means. Nowadays the practitioner was diffident about dealing with such cases; he sought other opinions and relied more on mechanical means of diagnosis. There had been great manipulative surgeons in the profession before the use of X rays.

Mr. J. E. H. ROBERTS said he held strongly that there was now in the profession far too much specialism, though admittedly orthopædic surgeons during the past 20 years had advanced the knowledge of surgery in a way that no other branch had been advanced. He considered that surgical knowledge and practice should be more diffused and used more by the general man. Cases of tuberculosis of joints he thought were more common than was generally suspected, and he described a case which was regarded as an instance of this condition, but old tuberculin caused no reaction, and a history of a past injury having been elicited he successfully treated the case by manipulation. Chronic rheumatoid arthritis he found became worse by rest. He also spoke of the common class of case in which pain in the back had been caused by trauma. One such case was seen by a colleague, who ordered a plaster-of-Paris cast for 18 months, but the patient would not submit to it. The speaker saw her and found a tender spot in the erector spinæ; he gave gas and he manipulated and fully extended the legs, and this cured her. He quoted other cases. On the general question he said there was a great need for these cases to be collected and demonstrated to students as a definite part of their training. There was too much to do in an orthopædic department for this to be carried out there, especially as it was necessary to keep in touch with the cases and to note their progress.

Mr. WHITCHURCH HOWELL agreed that diffusion of knowledge on manipulative methods was necessary. He had two medical friends who had been treated by bonesetters, one of them successfully. Both were attached to famous medical schools in London. One had teno-synovitis of the neck and no skiagram was taken before the manipulation by the bonesetter. The other had sciatica and limped badly; it had been going on for months. This last lady went into a home, where she was manipulated several times by the bonesetter in question, and at the present time she had loss of sensation on the outer side of the foot and it might be necessary to have a toe amputated. One case he had recently seen of congenital dislocation of the hip had been under treatment in London by a bonesetter for 18 months. Each time the mother talked to the manipulator he assured her it was distinctly improving, and that he would eventually get the hip into the joint. No skiagram was taken. In the last three weeks he had seen another case which was under a bonesetter. It was that of a child aged 3, who was being taken twice weekly to have manipulation for congenital absence of the right radius!

Mr. St. J. Dudley Buxton said it would be agreed that bonesetters seldom manipulated cases of tubercle, unless they were very inexperienced. If they met with such cases they usually sent them away and charged no fee. The lay press was ranged on the side of the bonesetter, and this was a great handicap to the regular practitioner. But a number of practitioners in the profession seemed to be afraid of carrying out manipulation.

Mr. Cecil Rowntree gave an account of a case in which he managed to be present at a reduction on a patient carried out by a bonesetter in a case of a lesion, possibly myositis ossificans, at the level of the transverse process of the second lumbar vertebra. The treatment was successful.

Dr. A. C. Jordan said these manipulators had gone through a fairly prolonged course of accurate training, and hence were likely to be better at manipulation than the ordinary medical man who had not been so trained. Therefore, in the same way as a medical man, having made his diagnosis, employed the best masseur he could find, he could also, having made his diagnosis, hand over his patient to the skilled manipulator. The remedy seemed to be to create a band of manipulators who could be employed to act under the doctor's orders.

The President agreed that something more might be done in the way of teaching manipulative surgery to the student. Not long ago the question of the revision of the medical curriculum was under consideration by the General Medical Council, whose committee discussed the question in considerable detail. That committee issued a recommendation to the licensing bodies and through them to the schools, that mechanotherapy should be an essential part of the medical student's curriculum, that term being meant to include manipulative surgery. There were general surgeons who took a certain number of dressers, who, during their dressership, had to be taught various branches of surgery. As had been said, the general surgeon could not be an expert teacher in everything, neither could he have cognisance of everything which went on in the case of every patient under his charge. Also, one's beds were too limited to teach the whole subject, and the beds had to be occupied by the more serious cases. A large number of patients coming to the out-patient department could be treated best by manipulative means; they might not be seen by the assistant surgeon or the surgeon. There was a tendency for the younger men in lecturing to choose advanced subjects, and to leave out what might be termed minor surgery. He thought it was an open question whether mechano-therapy should be made a compulsory part of the student's curriculum; the lack of time was the trouble, and he did not think advanced specialism was the true remedy. There was needed, however, some modification in the curriculum which would enable students to be automatically taught a number of the methods at present under discussion. His view was that many practitioners were afraid of boldly treating injuries of joints and their after-results. That was brought forcibly home to him during the war. He agreed with what Mr. Openshaw said in regard to the press. The press dearly loved to get up a "stunt" which was against some statutory body; they said the medical profession was a closed borough, governed by a body known as the General Medical Council, and that they did things they should not do. Therefore they were fair game for the press. Consequently if the press was approached in the proper kind of way it was a very easy matter for the irregular practitioner to get very favourable notices in a considerable part of the press. He was able to say that if one sent a statement to the press containing a true account of matters and it happened to be against the "stunt," the probabilities were all against such communication being published. The regular practitioner was at a disadvantage in this contest because he could not advertise. This matter was going to be very much more under consideration before the present year had finished, and much would be coming along which would need the close attention of the profession and of the medical societies if the medical profession was to remain in its present position.

### *Reply.*

Mr. Bristow reminded the meeting that this was not a discussion on specialism; his main wish was that the student and practitioner should be taught these things. He was not sure that "mechanotherapy" was a happy term to indicate to the generality of people that manipulative methods were meant. He dissented strongly from the view expressed by Dr. Jordan.

Mr. Elmslie said people had come to him with the remark that they were not sure whether they had approached the right person, whether they ought not to have gone to a bonesetter. Many did not realise that the qualified surgeon carried out manipulations. That was largely attributable to the attitude taken up by the press. During the last discussion on this subject in *The Times* very opprobrious remarks were made by Mr. G. Bernard Shaw against the masseur profession, and a short letter was sent to that journal from the Registered Society of Medical Masseurs, signed on behalf of the medical members by Sir Cooper Perry, explaining the position and training of members of that body, but it was not inserted. He concluded with a few words in justification of specialism in surgery.

## ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

At a meeting of this Society held on Jan. 21st, Colonel S. P. James being in the chair, Dr. James Hasson read a paper on a

### *New Method of Diagnosis and Vaccine Treatment of Leprosy.*

He said that the present methods of treating leprosy were far from satisfactory in many instances. The results of chaulmoogra oil, hydnocarpate, the morrhuates, and amino-arseno-phenol were contradictory. This was partly due to the metamorphic possibilities of the objective symptoms of leprosy, the variance of which was probably accounted for by the varying degree of intoxication of the patients. No leprologist could boast of having witnessed true cures with any form of therapy. He had therefore investigated a vaccine method, using a stock autolysate containing 15,000 million of *B. pyocyaneus* and about 5000 million of Hansen's bacillus to 2 c.cm. of physiological saline. Leprous patients had blisters induced on them with carbonic acid snow; these were emptied 24–36 hours later, and the sera of different forms, nodular, anæsthetic, and mixed, were incubated together at 36° C. for a period of from 50 days to three months. A mixed culture of *B. pyocyaneus* was then added to the serum (previously rendered incoagulable by the addition of a sterile solution of 2·5 per cent. sodium citrate), and the whole was centrifuged for 20 minutes. The requisite quantity of distilled water was then added, the bacilli counted, and the solution put up in 2 c.cm. ampoules. A symptom of very great value in early diagnosis was a subnormal temperature of 1° or 2°. It was because of this temperature that the bacilli were incubated at 36° C. only.

The method of Row, of Calcutta, using three months' old Koch's bacillus, differed only in his use of non-specific simple unmixed autolysate, and was undoubtedly sound. The action of both vaccines was explained by the formation, in the liquid of the vaccine, of antibodies excreted by the bacilli themselves. Besredka, of the Institut Pasteur de Paris, had shown that infected wounds cleared up rapidly when filtrates of old cultures of the causative organism were used therapeutically, even in cases where fresh vaccines had failed Besredka had used specific filtrates only, but the virtue of Row's non-specific method in leprosy was easily accounted for by the close relation between *B tuberculosis* and *B lepræ* The *B pyocyaneus* was included in order to induce an increase of temperature capable of "dislodging" the bacilli. Injections might be given intravenously or subcutaneously Intravenous injection produced a violent reaction in one or two hours with shivering and rise of temperature up to 104° or 105° F Twenty four hours later the patient would be quite well After subcutaneous injection the temperature rose only a degree or two After the third dose the nodules rapidly flattened and dispersed, while the achromic and anæsthetic patches became smaller and disappeared in 2–4 months There had been no case of relapse after 18 months, and one case of maculo-anæsthetic leprosy treated 14 months ago remained clinically and practically cured, the examination of excised tissue the Klinger-Hertzfeld reaction with Joltrain's antigen, and the Bordet-Gengou reaction all being negative

Dr Hasson demonstrated a case of Dr Manson Bahr's with an anæsthetic patch about $2 \times 4$ cm. above the right knee A section of excised tissue and scrapings of the nasal mucosa showed no bacilli, but blister fluid revealed their presence in abundance The blister was raised by carbonic acid snow produced in a simple wooden mould devised by Dr Hasson and called a "cryocanthere" Vaccine treatment had reduced the anæsthetic area to 1 sq cm and hairs were beginning to grow on it

Dr P H MANSON-BAHR said that his experience with the classical method of treating leprosy had been most disappointing and had impressed him with the absolute failure of the chaulmoogra oil preparations He had recently examined an undoubted case of leprosy treated by Dr Hasson's method and had been unable to find any trace whatever of leprosy save slight thickening of the ulnar nerves.

Lieut.-Colonel W P. MACARTHUR then delivered an address on

### *Old Time Plague in Britain.*

After discussing the varieties of fleas responsible for carrying plague, he pointed out that the disease was dangerous to the insect as well as to man, its œsophagus got choked with a plug of bacilli which it injected into the blood of the host. About 70° F was the optimum temperature, so that the disease was most rife in England in a dry, hot summer Plague was never spread from man to man, as the quantity of bacilli in the blood was very small, the culture had to be incubated in the flea. If the Black Death had been contagious it would not have taken a year and a half to spread over England. The plague of Justinian in 513 was the earliest epidemic that invaded this country It was not found mentioned in English records, but appeared in Irish and continental documents, in the latter of which it was called the "groin disease." In 661 appeared another outbreak, described in Irish records as bubonic. These attacks recurred continually throughout the Middle Ages, and were generally ascribed to famine In the fourteenth century came the "Black Death," a name that was not used until more than 200 years later The contemporary term was the "botch," a word corresponding to "boss" or bubo, which was a favourite term of abuse in the time of Knox, long before its modern equivalent "Boche" was made familiar This epidemic spread westwards from Asia, entering England at Weymouth in August, 1318, and thence sweeping over the country. Scotland escaped in the main and seized the opportunity to mass for an attack on England, but the army met the plague near the Border and 5000 died. A special prayer for protection against the plague of England still found in the Army service dated from this experience. There were no exact mortality figures of 1350, but from one half to two-thirds of the people died Judging from tithe records there were about 24,000 inhabitants of Norwich before the Black Death, and only 7000 after it. Three archbishops died within the year Yet still hope was found to triumph over experience, as one lady was recorded to have buried three husbands in three months! Most of the information was obtained from clerical records, and from these we learned that in East Anglia alone 800 parishes were left without incumbents, 80 of them twice, and 10 of them three times The Black Death was without exception the greatest calamity that had fallen on the human race within historic times; it broke up the feudal system and altered the course of history The confusion and chaos were like a great gulf breaking the continuity of history and tradition. The pestilence smouldered for 300 years after the chief outbreak. In May, 1440, Parliament adjourned to Winchester, a little later to Ludgate, then to Leicester and Reading, and finally closed down. Epidemics occurred in 1500, 1500, 1513, 1531, 1542, and 1547 In 1531 the Bills of Mortality first appeared; the Lord Mayor was ordered to report weekly the number of deaths due to the plague The first Plague Order of which the text survives in extenso dates from 1542, when all plague houses were ordered to be closed and marked with a blue cross and the words 'Lord Have Mercy On Us' Should any of the inhabitants of such houses receive special permission to go abroad they were to carry white wands 2 feet long All dogs were to be destroyed except watch-dogs, there was a strong idea that dogs and cats helped to spread infection. The sanitary conditions of the time were ideal for plague The floors were of loam spread with rushes amongst which were cast bones, beer, vomit, and excrement, none of which were ever removed, they were merely covered with more rushes The houses were crowded and ill ventilated, and the streets full of garbage and excrement. Rats ran everywhere and fleas were regarded as of no more significance than the clothes of the bed. The poet John Donne once observed a flea spring from his lady to himself, and touched by the bond of union thus set up went home and wrote a sonnet about it, ending up with the line—

> And in the flea our two bloods mingled be."

In 1553 2000 persons died of the plague in London in one week. Stratford-on Avon suffered badly, but Shakespeare's family escaped, and his father subscribed liberally to the relief fund. The first mention of John Shakespeare was his appearance before the court for having outside his door an accumulation of filth that offended even the sensitive noses of his neighbours Shakespeare suffered many things from the plague, for all theatres were closed whenever the deaths totalled more than 30 per week. In 1603 Shakespeare's company produced four plays at Hampton Court Palace since the theatres were closed for so long a time in London, and James I subscribed £30 for the relief of the distressed members of the company In this year the crosses on the doors and the wands were changed from blue to red, but this had no marked effect in checking the plague In 1625 occurred an epidemic—wherein 4000 died in London in one week—which was known as the "Great Plague" until that of 1665 effaced it In the latter year 70,000 were recorded as having perished, and this was undoubtedly an understatement, as every effort was made to conceal the true cause of death in order to avoid the restrictions Deaths ascribed to "malaria" in this year reached the unlikely figure of 5000 There were many concealed deaths from plague in the parish of St. Giles-in the-Fields in 1601, and the disease was endemic in the squalid, overcrowded, filthy "liberties" outside the city walls By the end of August, 1665, the usual flight had set in. The Lord Mayor and Aldermen and the stout-hearted Duke of Albemarle remained at their posts and stringent quarantine was enforced. The unfortunate people shut up for a month in infected houses were often robbed and sometimes murdered by the watchmen set to guard them. Eventually the quarantine orders broke down because there were too many houses to guard, and over 1000 corpses were collected by the watch-carts every night. Cats, dogs, swine, and rabbits were forbidden in the city and thousands were killed. It was thought that they absorbed effluvia from the dead bodies and carried infection in their fur. There was much dispute as to whether fires in the street were efficacious or not, and if so whether they should be of coal or of wood, and which variety of wood most possessed the mysterious antiplague properties. Finally rain fell and put the fires out, and the Lord Mayor sensibly refused to have them lit again. For 17 years after this plague deaths were recorded, and the real reason for its final disappearance was the development of a sanitary conscience among the people, producing an environment unfavourable to plague, which is essentially a disease of filth and overcrowding. All scavenging and sanitary measures were put under a central authority. The Fire of 1666 helped indirectly because the Rebuilding Act, hoping to prevent another such conflagration, forbade lath-and-plaster houses, and so sealed the doom of *Mus rattus.* Driven from the shelter of houses it encountered the rigours of the climate and, finally, the competition of *Mus norwegicus,* though this species did not become common till 40 years after endemic plague had disappeared in England. Thus the great European plagues of the eighteenth century left this country untouched.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held at the Leeds General Infirmary on Jan. 15th at which Mr. A. L. WHITEHEAD occupied the chair.

Dr. W. MACADAM read a paper on the uses and limitations of

### *Tests of Function in Medical and Surgical Practice.*

Lengthy, elaborate, and complex procedures, he said, are out of place in clinical medicine. The various tests of function are of little value if considered alone; they must always be viewed in relation to the clinical condition of the patient. Nor must inadequate function of an organ be regarded as necessarily synonymous with disease. A study of the amount of urea retention in the blood in conjunction with a comparison of the percentage of urea excreted in the urine is the simplest and safest guide to the state of renal function. But a high blood-urea is found in many conditions other than kidney disease. Even a high blood-urea plus albuminuria is not sufficient for diagnosis. Tests of hepatic function have so far not yielded the reliable results given by renal tests, and from the medical point of view they are disappointing. The most useful is the lævulose test; the value of such dye tests as phenoltetrachlorphthalein is still uncertain. van den Bergh's test, although not of much practical value in clinical differentiation of the various types of jaundice, is proving useful in detecting early or latent jaundice, and in distinguishing between hæmolytic and secondary anæmias. Dr. MacAdam emphasised the failure of basal metabolic rate as a diagnostic adjunct in those doubtful early cases of hyperthyroidism in which the clinician also is uncertain. As a measure of the efficacy of various lines of treatment and as a guide to the best time for operation the basal metabolic rate is, however, of distinct value.

### *Clinical Demonstration.*

Mr. P. J. MOIR showed two cases of hydronephrosis illustrating the usefulness of pyelography as a method of diagnosis and examination.

Dr. R. C. WALKER (for Dr. WARDROP GRIFFITH) demonstrated a case of thoracic aneurysm occurring in a man of 33 years. On admission to hospital there was a well-marked pulsating swelling of the chest, which subsided with rest and iodides. Dr. Walker expressed the opinion that the signs on admission left room for no doubt that the condition was one of aneurysm; but there was no history of syphilis, and the Wassermann was negative.—Dr. CURTIS BAIN (Harrogate) and Dr. R. A. VEALE both indicated that they were not convinced, and expressed the opinion that dilatation of the aorta due to aortic disease, probably rheumatic in origin, was a likely alternative.

Dr. C. W. VINING, in association with Mr. J. F. DOBSON, showed a child of 4 years upon whom the operation of thoracoplasty had recently been done for unilateral fibrosis and bronchiectasis following empyema at the age of 11 months. Parts of the sixth to the eleventh ribs had been removed, and Mr. Dobson believed that it would probably be necessary to remove two or three more before efficient collapse of the base of the lung was attained. Following the operation there had been an immediate decrease in the quantity of sputum.

Dr. VINING also showed a boy of 10 years with a three years' history of vomiting believed to be functional. No organic or toxic cause had been found to explain the condition, and the X ray examination demonstrated no obstruction, organic or spasmodic. A month previously the boy's condition was critical, the emaciation being extreme; he weighed only 27 lb. Following the passage of a stomach-tube the vomiting had completely ceased, and his weight was now 41 lb.

Cases were also shown by Dr. J. LE FLEMING BURROW, Mr. L. R. BRAITHWAITE, and Dr. W. H. ROWDEN.

## ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

### *Insanity from the Point of View of the General Practitioner.*

THIS Society met on two recent occasions to discuss this subject. Prof. ARCHIBALD YOUNG, the President. and Dr. W. A. PRIDE took the chair on the first and second evenings respectively.

Dr. R. O. ADAMSON said that insanity was to be regarded as a symptom and studied as such. It was in no way different from other symptoms dealt with by the general practitioner, and it should be approached along the familiar road of careful clinical investigation. The distinction between sanity and insanity was an arbitrary one, but it was important to distinguish what insanity was *not.* It was not a minor psychosis, a neurosis, or a hysteria. In family practice, he said, it was important to take advantage of every opportunity to study early cases and to treat cases, as far as possible, before certification.

Dr. J. H. MACDONALD, speaking from the point of view of an asylum physician, made a plea for earlier diagnosis of insanity and earlier removal of the patient to an asylum. Any disease was, of course, more amenable to treatment in its early stages, but it was particularly difficult to make contact with mental patients after morbid habits of thought and action had been established. Many cases of incipient insanity could be definitely checked and the onset of secondary symptoms prevented by appropriate treatment in the early stages. Not only from the individual but also from the sociological point of view the subject was of the utmost importance. Of 18,398 insane in Scotland, only 3014 were maintained by their relations and the remainder cost the State about £700,000 a year. The observation wards in the parish hospitals had proved of great service and the stigma of being "on the parish" might disappear under new health administration. Observation wards in a general hospital were not suitable, though more use might be made of out-patients' clinics similar to those already attached to some of the general hospitals. Properly organised asylums were probably the best means of dealing with the problem, but the public must be educated to regard them as "hospitals for mental disease," into which anyone, whether able to pay for maintenance and treatment or not, could be admitted as a voluntary patient. Social considerations were a powerful factor in influencing a decision against certification. Dr. Macdonald concluded by referring to the necessity for after-care to prevent relapses, and to some of the difficulties arising out of certification.

Mr. John Drummond Strathern, Procurator-Fiscal for Glasgow and the lower ward of Lanarkshire, discussed insanity as it affected criminal responsibility. There were two distinct classes of case in which acute difficulties arose: (1) cases of murder or grave crime in which a plea of insanity in bar of trial was raised; (2) cases of minor crime in which accused persons were usually certified under Section 15 of the Lunacy Act, 1862. It was frequently found that individuals of the first class had previously led a normal life and had shown no indication whatever of insanity. Such a prisoner might be examined by different medical men not unfamiliar with questions of lunacy—for example, by the divisional police surgeon soon after the crime, by the prison surgeon, and by mental specialists for the Crown—without any trace of insanity being found. Notwithstanding this, at a later stage mental specialists instructed by the defence would probably reach quite a contrary conclusion. This was an unsatisfactory state of affairs, and it was not easy to explain the reason for the conflict of opinion. The law was quite plain. An individual is responsible for his act unless he can show—the onus is upon the accused—that he was unable by reason of mental disease to know the nature and quality of his act, or, if he did know it, that he did not know that he was doing what was wrong. An insane person is held not to be responsible for a criminal act upon the ground that, by reason of his state of mind, he is incapable of formulating an intention to commit the crime. A criminal intention is essential in all acts of crime. Not only, said Mr. Strathern, was there complete conflict in medical opinion as to what constituted medical unsoundness in such cases, but very frequently there was actual disagreement among the medical specialists on the facts elicited by examination. Such a state of affairs was not creditable to the medical profession, and greater unanimity should be secured if possible. In his opinion the confusion arose from the failure of medical examiners to understand exactly what the law requires in order to establish a plea of insanity. One body of medical men appeared to be applying the legal definition of insanity, whereas those opposed to them were applying varying standards of their own and regarded a criminal lunatic rather as they would a private patient.

Many accused persons of the second class, continued Mr. Strathern, suffered from temporary insanity or insanity of a mild type from which they would probably recover; but many, on the other hand, were hall-marked criminals and dangerous to the lieges—in short, criminal lunatics and potential murderers, who should be kept under strict supervision permanently or at least for a prolonged period. Such persons might be certified and confined to an asylum, but they were often out again in a very few months by simply escaping from the asylum or by obtaining their release under a certification of soundness by the asylum physician. It was not long before their offence was repeated and they were again certified and confined to an asylum, only again to achieve their liberty by the same process. There was very marked contrast between the methods followed by the medical profession in dealing with those two classes of case. In his opinion society was entitled to be protected against lunatics of the latter class. Once crime was added to lunacy, the point of view of public interest should be paramount and the sentimental interest of the patient and his family should become subservient.

Prof. John Glaister said that there was comparatively little risk in certifying mental patients provided that the duty was exercised bona fide and with reasonable care. But a patient in whom there was some departure from normal mental health might be dealt with in another way, as long as the amount of departure did not bring him within the limits of certifiability. In Scotland such a person might be placed in a private, unregistered place, as a home, under a certificate given by a medical practitioner, under Section 13 of the Lunacy (Scotland) Act, 1866, for a period not exceeding six months. To the subject of criminal responsibility Prof. Glaister attached great importance, especially in view of the increasing frequency of pleas of insanity by persons accused of heinous crimes. The presumption of the law was that every person who had arrived at the age of discretion was sane and was accountable for his actions unless the contrary was proved. The person setting up a defence of insanity was required to prove not merely some taint of insanity, but the particular and appropriate kind recognised by the law.

Dr. Ivy McKenzie deprecated the present tendency to establish irresponsibility on what is known as modern psychological theory. It was no doubt important from the legal point of view to establish a defence, but in so doing the interests of society must not be sacrificed. Whilst admitting the desirability of recognising the various clinical types and grades of insanity, he thought that the application of the various technical terms and designations as well as the employment of vague and indefinite phraseology might, and did, prove confusing in the problem of criminal responsibility. Where, in his own practice, there was a question of plea at bar of trial, he was not guided exclusively by the legal precepts as laid down by the various authorities. His method of approach in any particular case was to consider, first, whether the symptoms presented conformed to any well-recognised syndrome, and secondly, whether the patient would have been a suitable case for admission to an asylum supposing no crime had ever been committed. Where criminals were committed to prison under Section 15 the responsibility of the doctor was even greater. About these cases, Dr. McKenzie agreed with the Procurator-Fiscal's point of view, and considered that quite a different standard was required from that governing the first type of case. Here there was an individual who repeatedly committed crimes, such as assault and indecency, on whom punishment had no deterrent effect. Such cases should be classified as insane and certified as such. The feeble-minded person could never be a criminal by reason of defect, but by something that he did—some positive harmful act—and the question here should be: Was the actual conduct prejudicial to society? The average defective was a very harmless person, but when he acquired vicious habits he might become dangerous and should then be classified as insane and dealt with accordingly.

Dr. D. K. Henderson considered that the whole question of mental disorder and defect—of crime, delinquency, and unemployment—was a problem which had as its unit individuals who, for one reason or another, had been unable to meet the stress and strain of ordinary social life. To deal with this radically an attempt should be made to get at the potentially disordered individual at an earlier stage. We must begin in the nursery and we must pay special attention to the school period. Children's teeth and eyes were carefully examined and looked after; there were special classes for cases of mental defect; but was sufficient attention paid to the "problem" child, sensitive and nervous, asocial and a dreamer? The general practitioner should always keep in mind the psychological aspects of (even physical) illness, and all such symptoms as tantrums, sleeplessness, irregularity of appetite, and nocturnal enuresis should be treated with great seriousness. The practitioner could also help by urging the value of treatment in a mental hospital, minimising as much as possible the stigma of certification. He thought that in the past asylum superintendents had not taken up a sufficiently definite attitude towards the problem of the mental health of the community. Turning to the medico-legal side, Dr. Henderson said that he believed law and medicine to be two different subjects altogether; he did not see how they could ever see eye to eye. The law dealt with the crime, whilst medicine dealt with the criminal. The law was therefore, to a certain extent, partisan, whereas medicine and medical opinion should be unbiased. Furthermore, it was constantly said that the plea of insanity in criminal cases was now completely overdone, whereas, in his opinion, quite the opposite was true. Mental disorder in relation to crime was not fully enough considered, and there were far more insane people convicted and sent to prison than there were sane people who escaped the rigour of the law on the plea of insanity. Dr. Henderson quoted statistics which made him certain that our prisons to-day were loaded with individuals in many respects not responsible, though he agreed that in major crime insanity was far too frequently pleaded.

Dr. MARION GILCHRIST thought that some provision should be made for senile dementia other than asylum care. She agreed with Mr. Strathern and Dr. McKenzie that, where homicidal persons were concerned, it was much more important to look after the interests of the sane than of the insane and that the sane should be protected from homicidal maniacs. Especially she thanked Mr. Strathern for his comments on the punishment of offenders against women and children. It was a disgrace to our civilisation that these men should be allowed to be in and out of prison, or in and out of asylums as at present, and it should be quite possible to detain them for life.

## ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Jan. 14th, when Dr. J. F. CHRISTIE, Vice-President, took the chair, and Dr. J. ROSS MCKENZIE read a paper on some advantages of

### *Gas and Oxygen Anæsthesia in Major Surgery.*

The technique of surgical operations, he said, had now reached a very high standard, but a number of early post-operative deaths were still unaccounted for. After describing a new apparatus embodying a triple sight feed for the administration of nitrous oxide, oxygen, and carbon dioxide, with or without ether, from which any combination and percentage of the gases could be obtained at will, he enumerated the operative advantages of gas and oxygen anæsthesia under the following headings: Ease of inhalation and induction, safety of patient, blood and circulatory apparatus unaffected, anoxæmia absent with normal metabolism, rebreathing with conservation of patient's own carbon dioxide, and de-etherisation with rapid recovery. Ether could be eliminated by making the patient rebreathe his expired carbon dioxide and by supplying this gas through the apparatus. Post-operative advantages included marked relief to the patient from nausea, sickness, and gastro-intestinal distension; normal functions of all the organs throughout the period of anæsthesia; and notable absence of chest complications. Dr. McKenzie put forward the suggestion that this form of anæsthesia acted as a protective against post-operative thrombosis and embolism. Surgical shock, he believes, is due more to a toxic anæsthetic, lack of oxygen, and loss of carbon dioxide, than to operative trauma and loss of blood. The difficulty experienced in inducing anæsthesia with gas and oxygen in young children could be overcome by using a face-piece with a graduated expiration valve attached directly to the gas bag.

Dr. A. OGSTON, Mr. A. MITCHELL, and Mr. W. ANDERSON were amongst those who took part in the discussion.

## LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of this Institution on Jan. 14th Dr. DINGWALL FORDYCE read a short paper on

### *Epilepsies in Childhood.*

He first referred to the difficulties of early diagnosis of epilepsy when the manifestations were those of incomplete forms such as visceral spasms. An epileptiform attack having occurred, the cause (apart from diabetes or uræmia) might be: (1) A gross intracranial abnormality such as birth trauma, infantile cerebral paralysis, or some form of amentia. Or (2) the attack might occur as a symptom of, or in conjunction with, primary amentia unassociated with gross intracranial abnormality. It was most important for prognosis to recognise whether or no amentia was present apart from the fits. He had recently had in review 129 children of school age, reported as being sufferers from epilepsy. In 35 of them there was evidence of an organic cause or of primary amentia (i.e., 18 cases of primary amentia, 10 of infantile cerebral paralysis, and 7 of birth trauma). The significance of such differentiation was shown by the figures for imbeciles. Of the 129 children, 32 were noted as imbeciles or probable imbeciles, and of these 16 were cases of idiopathic epilepsy, 9 of primary amentia, 4 of infantile cerebral paralysis, and 3 of birth trauma. In other words, half the imbeciles or probable imbeciles came from the group of 94 cases of idiopathic epilepsy and half from the group of 35 with organic lesions of the brain or primary amentia. Lastly (3) there might be no evidence of gross organic abnormality or of primary amentia. In this group were to be placed cases of (*a*) spasmophilia, (*b*) infantile eclampsia, (*c*) occasional fit or fits, (*d*) pyknolepsy, and (*e*) characteristic idiopathic epilepsy. In all the types of case in this group the presence or absence of an essential or idiopathic epilepsy might be conjectural, for a time at least.

MANCHESTER ROYAL EYE HOSPITAL.—At the annual meeting, which completes the 110th year of the hospital's activities, it was stated that the number of out-patients treated was 32,243, and of in-patients 2138. The average length of stay of in-patients in the hospital was 18·9 days, and the number of accidents treated was 8425, an average of 23·1 per day. The hospital serves an area embracing the greater part of Cheshire, all Lancashire, and beyond as far north as Carlisle, as well as the West Riding. A legacy of £10,000 is to be devoted to the new out-patient department. In spite of a rise in the ordinary income, it was found necessary to draw to the extent of £1200 on the hospital's accumulated fund.

PUBLIC HEALTH PROGRESS IN MANCHESTER.—Dr. R. Veitch Clark, medical officer of health for the city, has recently given some striking figures illustrating the marked improvement of public health in Manchester in the last generation. Public health is concerned primarily with the abolition of illness rather than with the reduction of death-rates. Among children under 5 the death-rate in 1911 was 56, and in 1922 it was 39, an improvement of 30 per cent. in ten years. Among children from 5 to 10 in the same period the death-rate fell from 3·9 to 2·9, a reduction of 25 per cent. The improvement among children from 10 to 15 years old was 27 per cent. The percentage of deaths below 5 years in 1904 was 43 per cent., in 1924 it was 24 per cent. The true index of the efficiency of preventive medicine is the increase of health and personal efficiency. About 1850 every boy at birth had an expectation of life of 39·9 years and every girl one of 41·8 years. In 1922 the expectation of a boy had risen to 54·6 years and of a girl to 58·6. At the age of 7 a child had attained more than half the height of an adult and one-third the adult weight. To make up the other half of its physical development it took 18 or 19 years. This put an undue strain on the body cells, and it is the object of preventive medicine to reduce this strain. In Manchester about 40 per cent. of the mortality occurred at the age of 25 or earlier. The conclusion to be drawn is that disease should be attacked within this period, when its influence, because of its effect upon development, was most malign. Health in childhood and youth meant efficiency in manhood.

# Reviews and Notices of Books.

## PRACTICAL PHYSIOLOGY.

Second edition. By E. P. CATHCART, M.D., D.Sc., F.R.S., D. NOËL PATON, M.D., LL.D., F.R.S., and M. S. PEMBREY, M.A., M.D., F.R.S. London: Edward Arnold and Co. 1925. Pp. 400. 18s.

THIS book is now divided into three parts, the first being devoted to experimental physiology, the second to physiological histology (a subject not formerly dealt with), and the third to chemical physiology. Among the many excellent features of the revised elementary experimental course are the important training in observation and deduction which it gives, and the large preponderance of experiments on the human subject. The authors point out that "the problem to be investigated and the methods of investigation are indicated . . . . but the results to be obtained and the conclusions to be drawn are left to the student." In the advanced course animal work naturally takes a more prominent position, but even here its application to man is never lost sight of, and whenever possible the human subject is used as the experimental animal. This part is profusely illustrated with good experimental tracings, which serve not only as a source of information to the student, but also as an encouragement to him to produce the neatest work which his limited experience in experimental technique will allow. Those tracings showing the attainment of the "steady state" in human and in frog's muscle, and the rapid exhaustion which ensues in the latter when the circulation is arrested, are especially fine. In Part II. the functions of living cells are studied as far as is possible by means of the microscope. Physiological histology, however, cannot confine itself entirely to the study of living tissues, but must include the preparation and study of tissues no longer alive. And just as the study of gross anatomy has preceded the study of physiology, so very frequently the study of minute anatomy must precede observations during life. These reasons are given for including in this course, not merely the methods of studying the living structures, but also the methods of preparing and studying these structures after death. Part III. contains an elementary course in chemical physiology, which follows the usual lines of an advanced course. The latter is to a large extent concerned with quantitative methods, and includes a description of the Douglas bag method for the determination of the basal metabolic rate.

The authors have been successful in condensing into small compass the experimental study of a wide physiological field.

## THE MENTAL GROWTH OF THE PRE-SCHOOL CHILD.

A Psychological Outline of Normal Development from Birth to the Sixth Year, including a System of Developmental Diagnosis. By ARNOLD GESELL, Ph.D., M.D., Professor of Child Hygiene, Director of Yale Psycho-Clinic, Yale University. New York: The Macmillan Company. 1925. Pp. 447. 16s.

THE main interest of this book consists as much in what it foreshadows as in what it actually achieves, though the extent of its achievement must not be under-estimated. Hitherto students of the psychology of the young child have confined themselves to careful observation day by day and month by month of individual children in their spontaneous activities. In this connexion the work of Pestalozzi, Perez, Froebel, Preyer, Sully (to mention only a few) has still much more than historical interest. But it was inevitable that the methods of estimating the average intelligence and achievement that have been applied to the school child by Binet and his successors should be extended to younger children and even to infants. This book contains an account of the work done on modern scientific lines at the Yale Psycho-Clinic under Dr. Gesell's direction, by observation and experiment upon normal children, with a view to determining the normal course of development of the child. Necessarily a considerable extension of the idea of what constitutes a "test" has been required. Some of these "tests" are really only accurate observations of a child's spontaneous movements and reactions to stimuli and of his physiological development; others are definitely tests, but more practical than linguistic. The results of the study of several hundred children are presented as cross sections of the stages of development reached at ten ages, ranging from 4 months to 5 years. The method of applying each test or "item," as the author prefers to name it, is fully described, and the comprehensiveness of the inquiry may be gauged by the large number—144—of "items" included. They are grouped under the headings of Motor, Language, Adaptive Behaviour, and Personal Social Behaviour. Very few of even a young baby's normal activities have been omitted, but it is doubtful if it is wise to accept a mother's statement regarding any particular action where the examiner has himself failed to observe or to elicit the action, the mother being scarcely ever an unbiased observer.

Those who practise mental tests of low-grade subnormal children will be grateful for the additional material put into their hands by this book; it supplements very usefully the weakness of most existing scales for the lower mental ages. It may become possible, after further standardisation of some of these tests on larger numbers of children, to arrive at intelligence quotients of some reliability for very young children. Premature grading is, of course, to be deprecated, but mental tests have tended to dispel the old notion that "late development" is anything more than a rarity. Included in the volume are some interesting studies of twins, showing remarkable correspondence of results, even in small details. Precocity and retardation are also discussed, with illustrative cases.

The book can be commended to the attention not only of medical officers who have to estimate retarded children, but also to the practitioner. He will find here means of attaining a truer estimate of a child's stage of development than he is frequently able to do when pressed by anxious parents for prophetic opinion.

## PSYCHO-PATHOLOGY.

*An Introduction to Objective Psychopathology.* By G. V. HAMILTON, M.D., Director of Psychobiological Research, Bureau of Social Hygiene, New York City. London: Henry Kimpton. 1925. Pp. 354. 21s.

ONE way of meeting the problem of the relation of body and mind is to exclude mind from our consideration and express human behaviour in mechanistic terms. Dr. Hamilton has made experimental studies of animal behaviour, has isolated certain reactive tendencies common to human and infra-human species, and then in a study of 200 nervous patients has used this classification to explain the behaviour of the patients and help in their treatment. In his therapy he employs methods which are now becoming established among psychopathologists, and the reader unfamiliar with these methods will find in the case-histories a useful introduction to practical treatment. The novelty of the author's presentation lies in the use of terms derived from his animal experiments, and we find such case-headings as "Persistent, Non-adjustive, Affective Reaction to Unsatisfied Major Cravings." But the striving for objectivity seems to fall short of its aim; "sexual-romantic cravings," for example, can scarcely be conceived in terms of animal behaviour or in any terms that exclude the consideration of mental processes. The demand that psychopathologists should exclude whatever cannot be verified by recognised methods of the natural sciences might be applied to exclude the speculative statement, concerning habit formation in the chick, that "synaptic connexions are made in its nervous system for a positive feeding-reaction to the object."

The clinical value of objective psychopathology is not clear, especially when we read, at the end of Chapter II., of a patient receiving a ten-page dissertation on psycho-analysis, which must surely leave him guessing as to the difference between the two theories. The author concludes with a denunciation of the "Freudian thesis"—frequently repudiated by Freud—that "sexual desire is, generically, the original source of all human action." The book contains many practical and original observations, but it is difficult to regard the author's theories as more than an ingenious attempt to evade a problem.

### THE HEALING GODS OF ANCIENT CIVILIZATIONS.

By WALTER ADDISON JAYNE, M.D., Emeritus Professor of Gynæcology and Abdominal Surgery, University of Colorado. New Haven: Yale University Press; London: Humphrey Milford, Oxford University Press. 1925. Pp. 509. 23s.

THE book before us is the second work published by the Yale University Press on the Philip Hamilton McMillan Memorial Fund established in 1922. It is not exactly a book to be read through, but rather an expanded dictionary which will prove useful to anyone who wishes to lay his hand on passages from both ancient and modern writers which throw any light upon the subject of healing gods. Dr. Jayne, possibly because there is so little known about definite gods of healing, has stretched his terms of reference widely. He includes deities remotely connected with healing, such as Aristaios, and the innumerable secondary deities of the Roman Pantheon, such as Prema, Vitumnus, Abeona, Adeona, Intercidona, Pilumnus, and Deverra, at whom St. Augustine poked fun in his great work De Civitate Dei. The three deities last named were personified at the birth of a child by three men carrying respectively an axe, a pestle, and a besom, with which they struck the threshold, that by the use of these signs of agriculture the wild wood spirits might be prevented from entering and harming the baby. On p. 444 Dr. Jayne refers to the portent of the birth of an hermaphrodite, and gives two references to Livy as to the procedure upon such an occasion. He would have found many other references in the Libellus Prodigiorum of Julius Obsequens, who gives about a dozen instances; the unfortunate child was disposed of by being thrown into the sea or into a river. Julius also refers upon many occasions to the birth of monsters, and upon one occasion to a child with an imperforate anus. Dr. Jayne deals not only with Roman deities, but with those of Egypt, Assyria, ancient India, Phœnicia, ancient Persia, Greece, and the Celts. Among the last mentioned was a deity named Mogons, whose name "probably means the 'increaser.'" Apparently Thackeray was not aware of this deity, or surely he would have added him to the list of ancestors of Alured Mogyns Smith de Mogyns (formerly Muggins), whose genealogical tree began with Shem and one of whose more modern forbears was Mogyn of the Hundred Beeves under Boadicea. Sir Alured had seven children, so Mogons did not forget his descendant. We commend Dr. Jayne's book, especially for the accuracy and fullness of his references.

## JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol. XXII. October–December, 1925.—In a paper on Brain Tumours in Children: their General Symptomatology, based on the analysis of 125 cases admitted to the National Hospital, Queen-square, Dr. Macdonald Critchley discusses the phenomena common to all varieties of cerebral tumour met with in pædiatric practice. The rarity of the disease in infancy is shown by the fact that only three cases in the series occurred in the first three years of life. As regards localisation, 59, or 47·2 per cent., of the tumours were situated in the pons or cerebellum; 34, or 27·2 per cent., in the cerebral hemispheres; and 14 were classified as pituitary or suprapituitary. Tuberculomata were the most frequent type encountered, the masses being often multiple, gliomata came next, and then sarcomata, while gummata, endotheliomata, and neurofibromata occurred in much smaller proportions. In addition to the triad of headache, vomiting, and papillœdema, an alteration in the child's character was often an outstanding feature. As a rule the march of the disease was progressively downhill, but in some cases, especially in tuberculomata situated in the ponto-cerebellar region, one or two remissions might occur.—Dr. E. A. Cockayne reports two cases, with photographs and skiagrams, of Hypertelorism. From consideration of the six cases now on record he concludes that hypertelorism is a congenital but not a hereditary condition.—Dr. Thomas Brushfield contributes an illustrated article on the Plantar Lines in Mental Defectives, based on the study of the feet of 918 children in the Fountain Mental Hospital. The following lines were noted: (1) Crease lines: (*a*) transverse caused by flexion, (*b*) longitudinal caused by the movement of bringing all the toes together, (*c*) a delicate network of fine lines. (2) Plantar lines or folds—viz., the oblique plantar line which was an almost constant feature in the Mongol, the transverse plantar line, and the transverse hallucial line. Dr. Brushfield maintains that, owing to the constancy and persistency of these lines in mental defectives, they should always be looked for and their presence regarded as a stigma.—Dr. F. Parkes Weber records a case of Morbilliform and Bullous Eruption with Jaundice from Luminal in a Choreic Girl. Morbilli bullosi could be excluded, as not only did the child never seem really ill and had practically no fever, but she had also a history of having had "measles" twice previously.—Dr. Parkes Weber also contributes a paper on Granuloma with Foreign-Body Giant-Cells due to the Injection of Ether into the Panniculus Adiposus.—Dr. Angelica Panayotatou, of Alexandria, reports a case of Cystitis caused by *Amœba histolytica* and *Schistosoma mansoni* in a Native Boy aged 7 years. Recovery followed treatment by intramuscular injections of emetine hydrochloride.—The abstracts from current literature are devoted to diseases of the genito-urinary system.

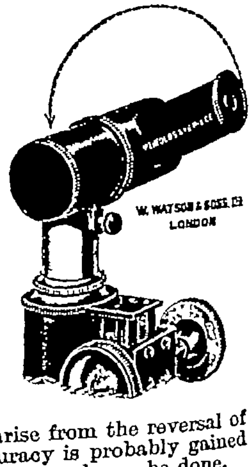
## THE PENFOLD INCLINABLE EYEPIECE APPLIED TO HÆMATOLOGY.

LABORATORY workers who have frequently to make use of a hæmocytometer have deplored the necessity for having the microscope in the vertical position, which is both uncomfortable and fatiguing. With the apparatus here illustrated the object on the stage of a vertically disposed microscope can be viewed as comfortably as if the instrument were inclined. The prisms are so adjusted as to permit of any convenient angle of inclination of the limb bearing the eyepiece. The hæmocytometer, with its liquid contents, remains flat on the stage of the vertical microscope, but the observer can perform the enumeration in the usual position for comfortable microscopy. I have not found any difficulty to arise from the reversal of the image and feel that accuracy is probably gained by the greater comfort in which work can be done.



The makers of the apparatus are Messrs. W. Watson and Son.

A. PINEY, M.D. Birm., M.R.C.P. Lond.

THE LANCET.

## MILK PASTEURISATION AND BOVINE TUBERCULOSIS.

WHOLE-HEARTED advocates of pasteurisation of milk-supplies base their faith on the fact that the reduction in the general bacterial content of the milk thereby achieved, and more especially the complete removal therefrom of occasional contaminants of high pathogenic importance, such as the bacilli of typhoid and tuberculosis, are considerations which should be fully weighed by those responsible for the public health. They are in no sense opposed to campaigns for the more general production of what is spoken of as "clean milk." On the contrary, they welcome all attempts to raise the standard of hygiene at the farm and dairy and likewise those efforts which the intelligent dairy farmer and the Ministry of Agriculture are making to eradicate tuberculosis from dairy herds. They recognise, however, that progress in these directions must perforce be tedious and that the health of the community, and more particularly of the child, cannot be allowed to suffer in the meantime if an immediate remedy is available. Their standpoint, in fact, would be precisely that of those who advocate prophylactic immunisation as an immediate remedy to be applied where general hygiene fails or lags.

Opponents of pasteurisation have complained (1) that the procedure advocated may whitewash a really grossly contaminated milk; (2) that the vitamin value of the milk is interfered with; (3) that pasteurisation does not perform what it claims to perform in the matter of germ reduction; and (4) that in particular there is no guarantee that occasional tubercle bacilli in milk are killed by the procedure in question. With regard to the first and third objections, there can, of course, be no doubt that grossly contaminated milk may acquire fictitious merit as judged by bacterial content and that certain forms of pasteurisation plant cannot effect the desired reduction in germs for the simple reason that disinfection by heat is a time process. It is certain, however, that inadequate cooling of milk after the pasteurisation process and carelessness in the preservation of milk, whether in the milk-shop or in the home or both, account for much of the subsequent rise in the bacterial content which has been alleged to take place in pasteurised milks. The difficulty can in great measure be overcome by delivery of the pasteurised and cooled milk in sealed bottles. The second objection has, we believe, a certain amount of validity, at least theoretically, by reason of the fact that the antiscorbutic vitamin does suffer some destruction during the pasteurisation process. Milk, however, is a poor source of this vitamin to start with and the defect can be readily made up with orange juice. As regards vitamin "B" and the fat-soluble vitamins, the chances of destroying these at the pasteurisation temperature are remote. The fourth objection to pasteurisation would be a very serious one if it were well founded, because we would be inclined to risk all the other alleged imperfections and disadvantages of the method if there was a certainty that the communication to children of tuberculosis of bovine type could be averted. That there should be doubt even at this time of day regarding the time-temperature factors necessary to kill tubercle bacilli in milk is, perhaps, not surprising when it is remembered that the aim throughout has been to show not that temperatures short of the boiling-point can kill tubercle bacilli in a certain time, but that these bacilli can be effectively destroyed if the milk is brought up to, and maintained for a due time at a certain minimum temperature, consistent with the preservation of the physical, chemical, and nutritive properties of the milk.

The time-temperature condition now generally adopted both in this country and in America is 62·5° C. for 30 minutes, excluding the period of time required for raising the milk to the desired temperature. Objection has been taken to much of the experimental laboratory work on this question on the ground that it has been carried out with milk artificially contaminated with cultural tubercle bacilli and that in naturally infected milk from cows with tuberculous udders the infective bacilli may be tucked away in particulate purulent or mucoid masses which the disinfecting process does not effectively reach. It has even been alleged, though without the slightest evidence, that the tubercle bacilli, if affected at all, are merely reduced in virulence. Whether a particular commercial plant can on the large scale repeat laboratory conditions of experiment is not germane to the argument, but it is obvious that unanimity in the effectiveness of a particular laboratory procedure is a necessary preliminary to any campaign designed to render commercial plants more effective and more deserving of public confidence. In a communication on this subject which we publish in our columns to-day, Dr. R. G. WHITE records a very extensive series of experiments carried out in the bacteriological department of the Lister Institute and designed to test whether naturally or artificially infected milk is rendered non-infective for guinea-pigs when subjected under laboratory conditions to a temperature of 62·5 ° C. for 30 minutes. The results of Dr. WHITE's experiments, which were all very carefully controlled, show clearly that no danger need be feared from milk, even massively infected with tubercle bacilli provided it is subjected to pasteurisation under the conditions prescribed. There is, indeed, some evidence that the period involved in raising the milk to the required temperature (about 8–10 min.) and the holding of it for periods less than the prescribed 30 minutes may suffice to annul the infectivity of the milk.

It is clear, however, that if commercial pasteurisation is to ensure freedom from bovine tuberculous infection, the plant must be so designed that the milk passing through the machine is really brought up to a temperature of 62·5° C. and maintained thereat for half an hour. Nothing less will serve.

## THE INTRAVENOUS ROUTE.

DRUGS may be administered in many ways, but, practically speaking, no matter what the portal of administration, they all reach the circulating blood. This is generally the result aimed at, for by no other method can the effect of the drug on the body as a whole be secured. If the substance be injected into a vein, then its dissemination by the blood-stream unchanged is ensured at the outset, and this would appear at first sight to be the most desirable method for the administration of remedies. Certain drawbacks, however, present themselves, of which undoubtedly the most important lies in the rapidity of the addition to the blood of a foreign substance. Quite apart from such factors as bacterial contamination and actual toxicity, there is a growing body of opinion that the injection of foreign substances into the blood-stream is in itself a risky business.

In America, where intravenous therapy is very widely practised, Dr. P. J. HANZLIK, of San Francisco, has repeatedly called attention [1] to this risk. After many experiments involving the administration of a wide range of substances he has arrived at the conclusion that there are at least two factors to consider. There is first the essential toxicity of the substance, and secondly what may be termed a non-specific toxicity. In experimental animals the intravenous injection of almost any substance is attended with definite changes which include fluctuations in the blood pressure, collapse, shock, and symptoms bordering on anaphylaxis. The seat of these changes may be at the site of injection, in the capillary bed, or in distant organs such as the liver. Further observations pointing in the same direction have been made by Dr. J. B. CHRISTOPHERSON and Dr. S. R. GLOYNE, at the City of London Hospital, and appear in the present issue of THE LANCET. They find that intravenous injection of antimony in animals produces capillary dilatation, serous effusion, and hæmorrhage into lungs and spleen, but that the chief brunt of attack falls on the hepatic cells and to a less degree on the kidney tubules. The same parenchymatous degeneration of liver and kidney was evident in the case of an accidental overdose of intravenous antimony in man, and the authors note the occurrence of hypersensitivity produced by antimony injections in doses well below the toxic limit. Whether or no the liver is associated with the non-specific toxicity is not definitely decided, but we have ample evidence that the liver suffers in the long run from the essential toxicity of the drug injected. It would almost seem as if this useful organ sets out to defeat the aims of intravenous medication by promptly absorbing and storing away the drug so administered, particularly if it be a metal. The kidney again excretes as much as possible, with the result that the concentration in the blood is rapidly diminished. The body, in fact, gets rid of the intruder from the blood as quickly as possible, no matter at what sacrifice.

At the present time intravenous therapy is chiefly used in such systemic infections as syphilis, in various tropical diseases, and in blood transfusion. In the last named a whole series of fresh and interesting factors have to be considered in addition to those already mentioned. Should lysis of the donor's blood take place, the resulting hæmoglobin is excreted by the kidney where, under certain circumstances, it may block the tubules, producing fatal obstruction and uræmia. This precipitation of hæmoglobin in the renal tubules has recently been shown by S. L. BAKER and E. C. DODDS [2] to depend on two factors in the urine—namely, its acidity and its salt concentration. Such precipitation can be avoided in animals by keeping the urine dilute and alkaline. It is therefore suggested that when there is evidence of hæmolysis in the receiver's blood resort should at once be taken to alkaline transfusion. These observations may have a direct bearing on intravenous medication and serve to confirm a recent editorial statement in the *Journal of the American Medical Association* that ignorance in this field of intravenous medication demands the greatest caution and conservatism.

## MONEYLENDING AND MEDICINE.

THE Joint Select Committee which last year considered proposals to amend the Moneylenders Act was more than once invited to detect affinities between the professions of moneylending and of medicine. One moneylender dwelt on the fact that both professions have to respect the confidence of their clients. Another was willing to see advertisement abolished because the doctors got along all right without it. There was evidence indeed of further bonds—if the word be not too equivocal—between medicine and usury. Athough one witness was shocked at the suggestion that he circularised the names in the Medical Directory, another admitted that he might sometimes address himself to all the doctors in a particular area. There was also produced for the Committee's inspection a circular which began:—

"DEAR SIR,—May we inform you that we specialise in making strictly private cash advances to medical practitioners, entirely without security, repayable by convenient monthly or quarterly instalments out of panel or other fees."

A recent pamphlet [1] places doctors third in the list of classes victimised by moneylenders, the first place being assigned to expectant heirs and the second to clergymen. Naturally, it is unlikely that the moneylending fraternity would overlook the medical profession. Its members, more perhaps than those of any other calling, have to mortgage the future by an outlay of capital—for the purchase of a practice, a house, or a motor-car—often in anticipation of the fees which will recoup the expense.

No laws have succeeded in suppressing usury. It cannot be denied that the lending of money is a valuable social service. Equally it cannot be denied that the system produces grave abuses. It seems trite and unnecessary to warn professional men not to borrow from moneylenders so long as money can be raised through a bank or an insurance company. And yet a well-known solicitor informed the Committee that he had often known "extremely clever professional men, doctors and others," entangle themselves desperately in the moneylender's toils, not because they were hopelessly insolvent at the beginning but merely because they were so unbusiness-like as not to realise that they could get the money elsewhere. He explained how he had sometimes freed them from their troubles and paid off the moneylender by raising funds from an insurance company or from a bank by means of two sureties or an insurance policy. It is probable that these men went to the moneylender because he offered the usual protestation of "strict privacy." The offer is illusory. As soon as the borrower gives his name and address the moneylender passes on the information to an inquiry firm in order to find out if there have been previous loans. Thus is explained the otherwise mysterious circumstance that as soon as a man has borrowed from one moneylender he at once receives a flood of circulars from others. When the borrower is harassed by an unscrupulous lender, the best defence is attack. Instead of waiting for the threatened writ from the moneylender, he should himself begin proceedings in the Chancery Division and ask for relief on the ground that, in the language of the Act of 1900, the rate of interest is excessive and the transaction harsh and unconscionable. The mere institution of such proceedings has been known to induce a marvellous reasonableness in the lender. But of course such action involves publicity, and publicity is a lever in the lender's hand. A shrewd observer advised the Committee that no change in the law would be satisfactory unless it deprived the moneylender of his three weapons—pressure of publicity, pressure of bankruptcy, and pressure of costs.

The Bill which the Committee's discussions evolved gives some defence against the threat of bankruptcy, but does not appear to adopt the proposal that all moneylenders' claims should be dealt with primarily in chambers and not in open court. One moneylender before the Committee frankly admitted that his trade had four abuses—misleading advertisements, preliminary fee-snatching, excessive interest, and harsh enforcement of the default clause. With all these the Bill deals faithfully. Circulars and advertisements are virtually prohibited, charges for preliminary expenses are forbidden, the force of the default clause is limited, and a savage rate of interest is mitigated It is proposed that, if the rate exceeds 4 per cent. per month, the court shall presume the transaction *to be harsh and unconscionable unless the contrary* is proved. This throws the onus of proof upon the moneylender, and (an important point) if he fails to discharge the burden he will presumably have to pay the costs of the action. The Bill goes further. It eliminates the moneylender's tout, prohibits the assignment of a loan, and requires the moneylender to be licensed, for which purpose he must obtain a certificate from the local bench of magistrates, the certificate being exposed to forfeiture or endorsement if he misbehaves. The proposed legislation will not make moneylending impossible; it is not intended to do so. It will, however, spike the guns of the unscrupulous moneylender and relieve the misery of his victims.

## THE HAGUE CONFERENCE ON SMALL-POX

AN important conference, arranged by the Health Committee of the League of Nations, met at The Hague from Jan. 4th to 7th to examine outstanding questions in connexion with small-pox, alastrim, and vaccinia. This conference was attended by Prof Ricardo Jorge (President), Prof. Madsen, Sir George Buchanan, Dr. Carrière, and Dr. Jitta, commissioners appointed by the Health Committee, with the following experts. Dr. Mervyn H. Gordon and Dr. F. R Blaxall (England), Prof. Gins (Germany), Prof Soberheim (Switzerland), Dr. Levaditi (Pasteur Institute, Paris), Dr. Terburgh and Dr. van Bonwdijk Bastiaanse (Holland), along with Dr. Norman White and Dr. Olsen representing the Secretariat of the Health Section of the League. The subjects had received preliminary consideration by the Health Committee and by the Permanent Committee of the Office International d'Hygiène Publique at a plenary session in Paris, when a draft scheme was drawn up by Prof. Jorge to form the basis of discussion at the conference As a result of its deliberations, the conference formulated a series of conclusions on the methods to be adopted for continuing and intensifying the research work now going on. It was decided · (1) To pursue the study of alastrim as fully as possible, from a clinical as well as from an epidemiological point of view. (2) To carry out certain inquiries at vaccine institutes with a view to formulating conclusions as to the essential matters over which Government control should be uniformly exercised, and also to secure data for comparison of the different tests proposed for measuring the potency of vaccine lymph. (3) To give close attention to the affections of the central nervous system which have been reported to have followed vaccination in some countries. The nature of these cases, which are extremely rare in comparison with the large number of vaccinations performed, is not yet determined, and for this very reason inquiry is needed. The conference decided to request the League of Nations to invite the various Governments with which it is in relation to collect information from their public health authorities, and to communicate it to the Commission. The Commission will then collate and report on all the data obtained, while technical investigation will be carried out by the expert members with the necessary assistance It is understood that a committee to be appointed by the Ministry of Health will carry out the work in this country in collaboration with the foreign observers.

# Annotations.

"Ne quid nimis."

## THE HEALTH OF THE ARMY IN 1923.

THE report on the Health of the Army for 1923 appears only ten months after its predecessor, and it is evident that the leeway of the war is being made up. The statistics presented all seem to be encouraging and there is evidence of a gradual lessening in disease. We may here quote some of the figures; those in decimals are proportions per 1000 men, and those in parentheses are the figures for 1922 given for comparison.

There were among officers 280 9 (298 3) admissions to hospital, for which malaria was the commonest single cause. The officers' death-rate was 3 03 (4 48); there were 10 deaths from injury and 7 from pneumonia. Losses by invaliding are unstated, as is usual in these reports Among other ranks admissions were 481·0 (515 8) and malaria was again the most frequent cause, though gonorrhœa was responsible for more time lost in hospital than any other disease. The death-rate was 2 84 (3 22) and 175 died from injury, 57 from pneumonia, and 50 from specified diseases of the digestive system. There were 41 suicides which are not included in the 2 84 per 1000 mentioned above. Invalids finally discharged were 14 50 (19 31), and this rate covers 451 men discharged for inflammation of the middle ear and 236 for tuberculosis. The proportion is almost identical with that noted in 1922. Admissions increased from malaria, sand fly fever, inflammation of tonsils, and dysentery, and decreased from influenza, venereal diseases, scabies, and diseases of the digestive system other than tonsillar and hepatic ailments. Iraq was the only important station which showed an increase of admissions, the most noticeable being dysentery, malaria, and sand-fly fever. Pulmonary tuberculosis, 2 9 (2 5), slightly increased in the Army of the Rhine. The report has been remodelled, and has now half as many pages more than formerly, and these are in larger type. It begins by discussing individually the most important diseases, and there follow special reports on medicine, surgery, hygiene, pathology, dental treatment, and the examination of recruits. Stovarsol was found to be most effective with relapsing amœbic dysentery, and tartar emetic with oriental sore. Recent alterations in the regulations for the accommodation of troops in transports have reduced tonsillitis by two-thirds, and diseases of the respiratory system by one-half. The report on pathology mentions a chronic tuberculous ulceration of the skin of the penis, for a time thought to be venereal, and a spheroidal-celled carcinoma of the appendix which recurred in the cæcum and caused fatal obstruction. The preparation of vaccines and sera at the Army Medical College is thought to have saved the State £12,050 in 1923. Dental treatment was required by 63 0 per cent. (74 23) of the men and two-thirds of them had their treatment completed. Scaling and cleaning of the teeth is done when necessary, and stomatitis and gingivitis were considerably reduced. As to recruiting, 370 04 (375 22) candidates for enlistment were refused at once and 40·09 (32·09) were rejected within six months. In this last group there were 2351 men, and it is estimated that each of them cost the State about £50. The chief causes of rejection were loss and decay of teeth, defective vision, defects of lower limbs, and deficient chest measurement. The causes of rejection which most increased in 1923 were middle-ear and heart diseases. It is observed that small-pox was very prevalent in this year in the United Kingdom, but great trouble was taken to secure necessary vaccination and re-vaccination, and no case occurred among the troops at home. Tuberculosis in the Army is thought to bear close relation to the standard of medical [illegible] It appeared twice as often, 2·9, in the Army of the Rhine as in the Army generally, 1·4. [illegible] the whole Army 56·4 (70·7) admissions to hospital for venereal diseases, which was a considerable reduction. They were halved on the Rhine, 136·3 (234·2), and this is ascribed somewhat pessimistically to the increased value of the mark. The report well repays study for its observations on the prevention and treatment of disease.

## CANCER IN TAR-WORKERS.

COMMENTING recently [1] on the death from cancer of a man who had been employed for 24 years at a municipal gas-works, we remarked that it should not be impossible to bring to the knowledge of all workmen concerned the protection which early treatment provides and the danger of delay. Sir Thomas Legge calls our attention to a leaflet on the subject issued by the Factory Department of the Home Office in June, 1924, entitled "Epitheliomatous (Skin) Ulceration as affecting Pitch and Tar Workers."

"Some pitch and tar workers develop small warts or ulcers on the skin of the face, arms, and very frequently in the neighbourhood of the private parts of the body, *especially on the scrotum, and it is these that may grow into the serious condition.*

"If a wart or ulcer appears on any part of the skin medical attention should be sought *at once*, so that a doctor can advise the proper treatment.

"All warts or ulcers do not necessarily grow into cancers, but those set up by pitch and tar and oil *may* do so, and are therefore best removed. This can be done quite simply. There is little fear of cancer developing under 10 years of employment and if the worker is under 35 years of age.

"The only treatment known to be successful at the present time is to remove the growth completely by operation, and therefore the smaller it is the more easily can this be done, and the sooner it is treated the greater the chance of success. *Delay may make all the difference between success and failure.*

"Fortunately, the form of cancer which is the most curable by operation, so that it will not recur, is cancer of the skin.

"It is, therefore, very important to keep the skin healthy and the pores of the skin open. The only way of keeping the skin healthy is by frequent washing with soap and water. The scrotum needs it as much as any other part. If this were done throughout life the trouble probably would not occur."

We are informed that 12,500 copies of the leaflet have been issued to the staff for distribution in factories in which tar is used and that it has been reproduced substantially in a leaflet issued by the Amalgamated Association of Operative Cotton Spinners and Twiners which has been twice distributed to the 30,000 mule-spinners in Lancashire.

## THE REWARDS OF MEDICAL DISCOVERY.

As our readers know, Sir Ronald Ross has long held that those who make important discoveries in medicine should receive ample pecuniary recognition from the State, preferably in the form of life annuities. He returns to the matter in the January number of *Science Progress*, and urges that part of the rather considerable sums which are now spent on encouraging research should be devoted to rewarding discoveries which have been made. In theory the proposal is so sound that it is difficult to find anything to say against it. If anyone would discover the cause of the common cold or of muscular rheumatism to be such that the knowledge gave us the means of preventing these appalling diseases, it is not extravagant to think and even to say that the State should give the discoverer anything he wanted, at any rate up to the level of dukedoms, palaces, and princely fortunes. And the man who found out how to prevent a disease such as pernicious anæmia, which by comparison produces a negligible amount of human suffering, might well have £1000 a year for life or something of that order.

The principle is sound enough; the difficulties arise only in its application. In the first place, who is it that discovers anything? Discovery is a process, not an event. The man who periodically steps out into the limelight and tells people about it and persuades them that there is something in it is only one of the links in a chain that had no beginning and will have no end. It is true that some of these links are very conspicuous and much more important to the advancement of knowledge than the average. There is, too, a good deal in the proposal that the truth and value of any theory is in proportion to the degree to which it opens up fresh fields to the imagination; this it will not do unless it wins pretty general assent, so that a higher place is rightly given to Darwin for making everybody think about natural selection than to the gentleman who anticipated his ideas in an appendix to a book on ships' timbers. But at the other end of the scale we have medical discoveries of the greatest moment for which it would be quite impossible to honour any individual by any method of selection more just than drawing names out of a hat. If the children who live by the reduction of infantile mortality in the last 15 years wanted to put up a monument to their preserver, they could not get much nearer than an Epstein panel. And in the second place, if it is possible in some instances to define discoverers, who is going to have the courage to define them and value them against one another? It might be done moderately well by a body as detached and remote as the Nobel Prize Committee but hardly by anyone nearer home. Perhaps the League of Nations would undertake it.

Such are a few of the more obvious practical difficulties. It is possible that they might in some degree be evaded and that some discoverers might be pleased, and more supposed discoverers more pleased, without the rest being dissatisfied beyond toleration. But we think Sir Ronald Ross is almost wholly wrong in thinking that such a system of rewards would "encourage" medical discovery. The synthetic idea which is nearer the common notion of original discovery than anything else generally comes by way of revelation, and like other revelations it comes to people who are not particularly looking for it. One man may by nature be more receptive than another and training may increase his sensitivity to some extent. But it seems scarcely reasonable for anyone to embark on a search for a revelation because it may be worth £10,000; there is no evidence that they are to be had that way.

## CATALOGUE OF HUMAN PROTOZOA.

TWENTY-FOUR years ago there appeared the first part of one of the most useful and comprehensive biological bibliographies which have ever been planned—namely, the "Index Catalogue of Medical and Veterinary Zoology," by Prof. C. Wardell Stiles and Mr. Albert Hassall. Begun under the auspices of the Bureau of Animal Industry, United States Department of Agriculture, the first section, comprising 35 parts, was completed in 1911. Running to over 2700 pages, it furnished a complete list of all published books, papers, articles, &c., dealing with medical and veterinary zoology, together with references to all reviews, critiques, and abstracts of these, arranged under the names of the various authors. The second, or Subjects, section of the Catalogue appeared from 1908 to 1920 as a publication of the United States Public Health Service and has, so far, dealt with the various species of parasitic worms hitherto found in man, in domestic stock, and in all other animals. In this section are to be found records of references to every known species of parasitic worm. The first part of the third section, or host catalogue, has recently been published [1] in the form of a small fascicle of 93 pages, and deals with the species of protozoa which have from time to time been recorded as parasites of man. In its original design it purported to be a guide for use by the class of medical zoology in the Hygienic Laboratory, but its scope is actually much more extensive than that and, indeed, it will prove a much-prized addition to the library of the specialist. Prof. Stiles needs no introduction to the circle of English zoologists, for his name has long been well known for his persistent efforts to stabilise modern zoological nomenclature. For the most part the entries in the Catalogue do not diverge much from the teachings of standard English text-books. The generic name of the parasitic amœbas is, however, written *Endamœba*, not *Entamœba* as so frequently occurs, and the valid species are given as *coli*, *histolytica*, *gingivalis*, and *muris*. The *Flagellata* and the *Sporozoa* are treated more or less according to rule, and we find the *Spirochætacea*, or spirochætes, included as a subdivision of the flagellates. The classification of the spirillar organisms has always provoked much debate, the trend of which is impartially indicated. The malaria parasites receive full consideration, and special attention is devoted to the somewhat difficult classification of the *Piroplasmidæ*. Not the least interesting section of the work is the last, entitled "Protozoa, Miscellaneous," amongst which we find such entries as *Chlamydozoa* (*vera* and *strongyloplasmata*), *Protobios*, *Rickettsia*, *Unicellula* and others which have in recent years become prominent in connexion with the study of cancer and the filtrable viruses.

## REPAIR OF THE URETER.

WHEN a segment of a ureter has been removed, either by accident or by operation, and the ureter can be neither implanted into the bladder nor united end-to-end, is there any method by which the urine can be conducted into the bladder? Dr. L. L. McArthur[1] reports a case in which he applied, with success, to the ureter the method which he has employed for the common bile-duct. The left ureter had been divided eight months previously by a severe blow which also fractured the left three lower ribs and the left transverse processes of the second and third lumbar vertebræ. The result was a lumbar urinary fistula. At operation the ureter was found divided 2 inches below its upper end. The ureteral ends were 1 inch apart and could not be brought into apposition. Dr. McArthur describes his technique as follows: A longitudinal slit was made in the side of the proximal portion of the ureter, sufficiently long to admit two catheters. One of these, a rubber urethral catheter, was inserted upward to the renal pelvis; the other, a ureteral catheter of good size, downward so as to pass out of the cut end of the renal portion and bridge the gap to the cut end of the vesical portion. The two cut ends of the ureter were then approximated as closely as possible by absorbable stitches. The catheters were then brought to the surface and permanently secured to the skin by stitches or other device. The urine from that kidney was thus diverted from the field of operation during the time of epithelisation. The body tissues were thus able to heal around the catheter bridging the gap between the renal end and the vesical end, the catheter simply remaining in situ until, in the judgment of the operator, an epithelial lining had had time to grow between the ends. Dr. McArthur does not claim to have determined the length of time required for epithelisation. In the case recorded, after the catheters had been placed in position, the gap between the ureteral ends was diminished by sutures to ½ inch. At the end of nine weeks both catheters were removed, when no further urine escaped from the wound, which healed immediately, the quantity of vesical urine being doubled at once. Nineteen months after operation the patient was well in every respect. Dr. McArthur considers a fascia transplant to be unnecessary for epithelisation of the gap, and believes that epithelium grows from each end of the divided ureter and lines the tissues surrounding the portion of catheter which bridges the gap. No mention is made of the possibility of ultimate stricture at the site of the gap.

## INSULIN DISAPPOINTMENTS AND HOPES.

THOSE who hoped that the administration of insulin to a diabetic might lead to the cure of the underlying disease are apparently to be disappointed. As a result of observations lasting from 11 to 18 months on five selected cases of diabetes mellitus, no evidence has been obtained by Dr. G. A. Harrison[1] of even a partial remission of the disease. The daily intake of carbohydrate, protein, fat, and calories remained fixed throughout. The dose of insulin was adjusted to the fixed diet according to the results of estimation of the blood-sugar content. All five patients needed as much or slightly more insulin at the end of the period of observation. Such fluctuations in dosage as occurred are considered to be due to the difficulties in balancing the dose accurately against the diet, to increase in metabolically active tissue, and to variations in the strength of different batches of insulin. Using the same batch of insulin, on a fixed diet, with the patient's daily routine kept as regular as possible, the blood-sugar curve remained remarkably steady. Every now and then, on changing over to a new batch of insulin, a patient suddenly appeared to relapse, or, on the other hand, suddenly developed hypoglycæmic symptoms. Simultaneously, the blood-sugar curve rose or fell. These differences between batches were much less noticeable in 1924 than in 1923, when the methods of standardisation were in their infancy. During the last six months of the investigation (September, 1924, to February, 1925) all these special patients were treated by the same batch of insulin, which arrangement Dr. Harrison describes as a great boon to the patients and to himself. He recognises that every possible care and skill has been exercised to standardise insulin, and notes that since the spring of 1925 successive batches have appeared to be of more uniform strength. This period probably corresponds with the use of the new comparative method of assay devised by Mr. Marks, of the National Institute of Medical Research. It is stated in the recently published report of the Medical Research Council that further experience with this method has confirmed its value. Quantitative clinical tests by Dr. Harrison and Dr. R. D. Lawrence on volunteer patients, compared with the laboratory findings, are said to show a correspondence so satisfactory as to warrant the conclusion that the rabbit test in the form devised by Mr. Marks is, if carefully performed, capable of detecting any difference of activity which the most elaborate clinical observation could discover, and that a supplementary clinical test ought not to be required. This is very reassuring, especially since the National Institute of Medical Research has accepted, at the request of an International Conference, the duty of preparing and keeping the international standard of reference of insulin. A large supply of insulin, received from institutes and manufacturers in different countries, was purified and converted into the form of a dry, stable hydrochloride. Simultaneous determinations were made in five laboratories in the United States of America, Canada, and this country, the results varying only from 8·4 to 8·8 units per milligramme of the dried preparation. As a result, the International Conference decided that this preparation, preserved at the National Institute, should be the international standard for insulin, and that one milligramme thereof should be taken to contain eight units of insulin. Samples of this standard have already been supplied from the Institute to the responsible authorities in 10 countries. It may be hoped that we have now reached the stage when a diabetic, even if condemned to a constant dosage of insulin, may travel abroad without fear of being unable to obtain a preparation exactly corresponding to that which keeps him well at home.

## THE UNIVERSITY OF LEEDS.

WE published in October of last year an appeal made in behalf of the Medical School of Leeds University, and the close association of the school with men whose names will ever be eminent in the medical profession made a favourable reception certain. In the same issue (Oct. 17th, 1925, p. 821) will be found a sketch of the growth of Leeds University enumerating the leading points of a striking history of development. We have received this week from a correspondent in Leeds the following plea for the University in supplement of the appeal made last October, and showing the success which has already crowned the efforts made :—

"To anyone who has had the opportunity of observing the development of the University of Leeds the present appeal for the large sum of half a million pounds will appear fully justified. The Yorkshire College of Science, widened in its scope by the formation of a department of arts and simplifying its title to that of 'The Yorkshire College,' became ripe for university status in virtue of its amalgamation with the School of Medicine, and it was in fact admitted as one of the three constituent colleges of the Victoria University in 1887. Into the changes which have led to the founding of the independent University of Leeds it is not necessary to enter. Leeds was indeed opposed to the disruption of the University, but no one can now for a moment have any hesitation in saying that the establishment of three independent universities in place of the old federal university has been the best thing for each of them.

"Many important landmarks have been passed by the Yorkshire College of Science, by the Yorkshire College—both before and after its becoming a part of the Victoria University—and by the University of Leeds, since the first-named of these began its work in temporary premises while the first portions of the permanent buildings were being put up on the site that is now so fully covered. The amalgamation with the school of medicine and the formal opening of the College buildings by the late King when he was Prince of Wales was in a few years followed by a great effort which resulted in the building of the new Medical School and the provision of a library and of the great hall of the University. These were opened in 1894 by our present King when he was Duke of York. The University was also honoured by a visit from King Edward in 1907 when some new laboratories were opened.

"The more urgent necessities of the University are as follows: The provision of a first-class library—the present accommodation for books being quite inadequate—larger and better lecture theatres, and, above all, a great extension of laboratory accommodation. The Medical School which was the expression of so much thought and care—and no one who saw it develop can forget the great work done by Mr. Scattergood, who was Dean of the Faculty of Medicine at the time it was built—is now too small, though it is satisfactory to note that very little alteration or scrapping has been required. It is clear, however, that the great development of the pathological department calls loudly for a separate pathological institute in immediate relationship with the present school buildings and with those of the infirmary. By arrangement much of the pathological work of the infirmary is carried on in the laboratories of the infirmary by the staff of the University under the direction of Prof. Stewart, who is also honorary pathologist to the infirmary. The provision of a pathological institute or block will be one of the first things undertaken under the new scheme.

"Though the appeal was launched as recently as last October at a public meeting presided over by the Duke of York, promises have already been received for £262,000. One donation calls for special comment. In connexion with the formation of a Cancer Research Centre for Yorkshire a luncheon was recently given to a representative gathering of ladies and gentlemen of Leeds and of the county by Lord Lascelles. At this luncheon Lord Lascelles was able to announce that he had received promises of £23,000 towards the project. Sir Algernon Firth then announced that his donation of £5000 which he had promised to the University Appeal Fund was to be increased to £25,000, which he was to give to the University through the Yorkshire Council for Cancer Research, on the understanding that this was to go towards the provision of a pathological institute as a part of the University with special laboratory accommodation for persons engaged in cancer research. The generosity of Sir Algernon Firth therefore ensures the very early realisation of a great hope which has been in the hearts especially of the members of the Faculty of Medicine, but which also has been an aspiration on the part of the present Vice-Chancellor and of his predecessor. Stimulated by the action of Sir Algernon, many offers of assistance came in at once and at the end of the meeting Lord Lascelles was able to announce that his promises had passed £30,000. Thus the Yorkshire Cancer Research Centre makes a good start with £55,000 towards the £75,000 which has been mentioned as the minimum required to carry on the work efficiently."

We referred last week to the magnificent generosity of Sir Algernon Firth in connexion with the Yorkshire Cancer Campaign. Such instances of individual generosity will in the end enable the evasive problems of cancer to yield their secrets—that is our assured belief. The fruits of intensive research may as yet be small, but not only are they real but they are full of broad promise.

## REVEALING UNKNOWN LONDON.

THE healthy human body is unconscious of most of its functions; the majority of its processes go on quietly without supervision or report. In the same way the healthy city shows little evidence of those activities which maintain its health, and it is only on the rare occasions when there is a failure of water-supply, an overflow of storm water, or an epidemic of food poisoning that the average citizen remembers (usually without enthusiasm) that reservoirs and drainage and sanitary inspectors do, in fact, exist. Huxley was accustomed to say that deep breathing and a stomach of which one was never conscious were the best equipment for life, and many right-minded Londoners will apply the statement to fresh air and drainage. Nowadays, however, it is felt that the more a man considers his colon the more healthy he will be, and it is not surprising that the London County Council, tired of receiving kicks instead of halfpence, should insist on London having an elementary knowledge of its main drainage. In a series of booklets the Council is justifying its existence to the ratepayer, who does not know where his money goes and has no idea how carefully he is looked after, and the latest of an attractive series entitled "What the L.C.C. does for London" is devoted to public health.[1] The booklet is exactly what is required; it is simply written, well illustrated, and thoroughly interesting. A map of the tremendous sewerage system of the county adds greatly to the fascination of unknown London, and the section of the book which describes the main drainage is pleasantly instructive. It is stated, in a summary, that in 1889 the daily discharging capacity of the outfalls under the Board of Works was 688 million gallons, and of the storm relief pumping work 30 million gallons. The Council in that year took over the management of main drainage and has increased these figures by 814 million gallons and 817 million gallons respectively, so that the total capacity is now over 2349 million gallons, as compared with 718 in 1889. This figure is being still further increased. The daily average quantity of sewage flowing to the outfalls is about 250 million gallons, which is equivalent to a stream 20 feet wide and 5 feet deep flowing continuously at a rate of three miles an hour. A total of about 100,000 million gallons of sewage is treated each year at the Barking and Crossness stations, and over 2 million tons of sludge are also dealt with. The fleet of vessels, so familiar to travellers on the river, which conveys the sludge out to Black Deep, 12 miles off the Essex Coast, is being reorganised and will comprise four steamers of 1500 tons capacity and one of 1000 tons.

The other activities of the Council—those of an active and enlightened health authority—are mostly familiar to our readers, and it is unnecessary to mention more than one or two as examples of their results. Under the heading of Medical Inspection and Treatment we learn that in 1924 the proportion of school-children requiring treatment was 30·7 per cent. compared with 44 per cent. in 1918. Children suffering from lack of nourishment accounted for 5·9 per cent.

---

[1] The London County Council and what it does for London: Public Health. London: Hodder and Stoughton, Ltd.; University of London Press, Ltd. Pp. 35. 6d.

of these, compared with 12·8 in 1913; 17 per cent. more children leave school to-day with sound teeth than in 1913, and the proportion of children with defective hearing has been halved during the past ten years. At a time when there is much misinformed public opinion on medical subjects it is gratifying to find so instructive a work issued for the education of London's citizens.

## MYOPE CLASSES.

THE report of the Council of British Ophthalmologists, a body representing the ophthalmic branch of the medical profession in Great Britain, which we print in another column, should be studied by all members of education authorities. A certain proportion of the children in our schools, without being blind, see so badly that they are totally unfitted for the ordinary school curriculum of book and desk-work. A number of these owe their defect to corneal nebulæ resulting either from corneal disease or from interstitial keratitis. Others have already become so myopic that even during school life they must be treated as partially blind. A much larger proportion of myopes, when appropriately corrected with glasses, see quite well enough to join the other children in the ordinary classes, but in their case, when the myopia reaches a certain degree, although visual acuity may remain good, it is not in the interests of the child to continue his or her education in the ordinary way because it has been proved that to do so may be prejudicial to his eyesight when he gets older (cf. THE LANCET, 1924, i., 907). For the sake of these different classes of children the London County Council so long ago as 1908 opened the first "myope school," but as the report says, it has been found that the best interests of these children are served if such classes are held in association with elementary schools where the oral teaching and physical exercises given in the ordinary classes are available. Unfortunately, the number of places in these myope classes is as yet by no means adequate to the need. Even in London, which takes the lead in this respect, there is only accommodation for 915 children, and in the rest of the country the supply is almost negligible. The reason for this, no doubt, is twofold—that such classes require special training in the teachers and that they must be limited in size, the maximum number recommended being 20. Both these essentials involve extra expenditure, and as we have been recently reminded, the present is not a time when such demands are likely to meet with a ready response. Nevertheless, the importance of the subject fully justifies the Council of British Ophthalmologists in recommending that in all large centres of population such special classes should be established, and further, that special instruction should be given to teachers and parents on the education and management of children with defective sight.

## COLLECTED PAPERS FROM THE LONDON SCHOOL OF TROPICAL MEDICINE.

WHEN the London School of Tropical Medicine became the Tropical Division of the new School of Hygiene, founded in 1924, it was decided to continue the "Collected Papers" of the older institution in a slightly altered form, and the first volume[1] has now appeared. It is under the same able editorship as the "Collected Papers" and consists of two parts, one containing addresses of a more or less general character delivered from time to time by the Director, Dr. Andrew Balfour, and the other 35 laboratory studies reprinted from various professional journals. The charm of the Director's style is well known and it is pleasing to have seven of his essays gathered here together. In the first, "New Conceptions in the Teaching of Public Health," he takes as his text a Chilian address wherein England is cited as "the cradle of hygiene," and reviews the changes in the hygienic outlook during 30 years and the aims of the new school. In his discourse before the Royal Institution that accompanied the Rockefeller cinematograph film he weaves a fairy tale from the history of malaria, tracing its destructive course from the night when "the angel of the Lord . . . . smote in the camp of the Assyrians an hundred and fourscore and five thousand," to the time when the enemy met its defeat at the hands of Ross and Manson and, still later, was harnessed to the chariots of its victors by being used as a therapeutic agent in the treatment of general paralysis. His third lecture makes live even the dry bones of the Provisional Scheme for the Diplomate in Public Health, while his fourth is a general survey—both historically and geographically—of "The Trend of Modern Hygiene." In "Vistas and Visions" he essays to attract Glasgow students to the colonial medical service by sweeping them on a magic carpet over the whole of the British Empire and giving them glimpses of the problems still awaiting solution. Into this journey he infuses a thrill and a romance that many a novelist might envy. "A Bit of the Bog" describes a journey through the Sudanese province of Bahr-el-Ghazal, while the last essay deals with the justification for the term "tropical disease."

The original papers reproduced in this volume have all been printed before, but it will be useful to the research worker to have them collected in one volume. Of particular interest to public health workers in this country are the papers by Dr. E. Hindle and Major H. C. Brown on Spirochætal Jaundice in Great Britain.[2] Mr. T. W. M. Cameron's article on Parasitic Diseases in Pigs and their Prevention, Colonel A. W. Alcock on the Anopheles Mosquito in England,[3] and Dr. Hindle on Leptospira in London Waters.

## A FACIAL REFLEX.

Dr. Filippo Modonesi, of the Ospedale Maggiore, at Bologna, published[4] as far back as 1905 a description of a facial reflex which may be of importance in the diagnosis and prognosis of cases of severe apoplexy. In such cases where there is deep coma the relaxation of the whole body and abolition of motor reaction do not permit us to ascertain which is the paralysed side, especially as the ordinary symptomatic reflexes may be absent. The reflex consists in contraction of the facial muscles of expression caused by pressure on the bulbus oculi. Even in conditions of coma this "bulbo-mimic" phenomenon persists for a long time, and may be evoked when other means of exciting motor reactions fail. Compression of the ocular bulb is a convenient method, and one which may be graduated at will to act on an extensive terminal zone of so sensitive a nerve as the fifth. When in cases of coma the bulbo-mimic reflex is present on one side while it is found wanting on the other, we are justified in admitting an organic lesion of the opposite hemisphere. On the contrary, the persistence of the phenomenon on both sides serves as a means of differentiating other comatose conditions, such as uræmic, diabetic, or toxic, from those which accompany a circulatory lesion of one hemisphere. Only in very rare cases of profound coma is there found complete loss of motor reaction to compression of both bulbs. This reflex phenomenon is in some measure analogous to cortical reflexes, for when the coma disappears and the deep reflexes reappear, the bulbo-mimetic phenomenon remains abolished or diminished analogous to what happens in the normal cutaneous reflexes or the hemiplegic side. The bulbo-mimetic reflex described by Dr. Modonesi is useful as a clinical sign for the early diagnosis of hemiplegia and for determining the site of circulatory disturbances of the brain in comatose conditions, distinguishing them from uræmic and diabetic coma, and also as a prognostic sign of grave significance in bilateral absence of the phenomenon. It may further serve as a useful sign as evidence of a peripheral paralysis in subjects in whom the ordinary method of investigation is not easy, as in the insane or alcoholic, and in children. Dr. Modonesi's publication of his observation of the bulbo-mimetic reflex preceded for some time that of other similar reflexes by Pierre Marie and C. Foix. In the latter's "Signe de la Face" the reflex action of the muscles of expression is obtained by pressure, not on the globe of the eye, but on the ascending branch of the occipital nerve. In each instance it would appear that a contraction of the facial muscles is produced by pressure of a painful character, and the two reflexes are not integrally different.

## PURU.

The specific infective disease caused by the *Treponema pertenue* is most commonly known by the name applied to it in Africa, yaws or frambœsia, but it also occurs in other parts of the world under various designations. Thus in Ceylon it is called "parangi," in Fiji "coko," in the Pacific Islands "buba," and in the Federated Malay States "puru." The committee for public health education of Malaya has recently issued a pamphlet[1] on the disease, written by Dr. A. Viswalingam, with the object of encouraging close coöperation between public health workers and the general public in that part of the world, so that this intensely crippling disease may be eradicated. It is estimated that 60 per cent. of the natives suffer or have suffered from the disease which afflicts all ages, but is more prevalent in childhood, and particularly abounds in insanitary country districts where the filth and general unhealthy conditions favour the occurrence of the disease. Spread by sexual intercourse is apparently very uncommon, the more usual course of events being the entrance of the spirochæte through trivial wounds and abrasions on exposed parts. The incubation period varies from a few weeks to months, and the initial lesion is found at the site of infection and consists of a granuloma which arises in the deep tissues of the skin. A more characteristic initial lesion is the occurrence of one or more small papules which increase in size and secrete a viscid yellowish discharge. The second stage consists of eruptions which appear in successive crops and may last for years. Small granulomata appear some weeks or months after the parent sore and are accompanied by an irregular fever. Discrete forms are common in older and confluent forms in younger people. Pitted sores upon the feet are very common, and great thickening of the skin and bones of the arms and legs also occurs. The third stage consists of an exfoliative dermatitis of the palms and soles which may go on to a more severe thickening and fissuring, while the skin loses its pigment in patches. Treatment by salvarsan and its derivatives gives excellent results, as is shown by the photographs accompanying Dr. Viswalingam's monograph. Similar results were obtained by Dr. Winckel in Java, as our Berlin correspondent reported last week. The Federated Malay States Government has placed salvarsan within the reach of all sufferers. The question of prevention is largely bound up with matters of personal and domestic cleanliness, and measures are being undertaken to eradicate the disease by hygienic means. Dr. Viswalingam points out that some of the failure to curtail the disease in the past has been due to its being confounded with such other diseases as lupus, leprosy, and syphilis. He emphasises, however, that its symptomatology renders it a distinct disease, but it is unfortunate that in his otherwise excellent account of "puru" he makes no mention of the Wassermann reaction which other observers have found consistently positive in African "yaws."

---

## CHORDOMA.

The occurrence in relation to the vertebral column of tumours derived from notochordal tissue was clearly established by Ribbert in 1894. They are rare, but probably not as rare as they seem, for a certain number are doubtless unrecognised and unrecorded. A comprehensive account of the condition in the January issue of the *Journal of Pathology and Bacteriology*, by Prof. M. J. Stewart, of Leeds, and Dr. J. E. Morin, summarises what is known in a useful way and should lead to the identification of further examples; once it is known, the tumour may often be recognised at first sight. It occurs chiefly in situations corresponding to the ends of the notochord, *i.e.*, in the neighbourhood of the spheno-occipital synchondrosis and in the sacrococcygeal region, about equally in each; only 3 cases out of 57 have been described in other places. More frequent in males than females, cases have occurred at ages from 16 to 72, the age of the sacral cases being distinctly the higher. It is usually of low malignancy, slowly infiltrative and destructive, especially of bone, and generally without metastases. The head cases give the symptoms of a slowly growing tumour of the base of the skull—headache, giddiness, failure of sight, cranial nerve palsies, &c. The sacrococcygeal cases suffer at first mostly from pain, and later pressure on nerves may give various motor, sensory and trophic disturbances in the legs; if the tumour extends mostly inwards pressure on the bladder and rectum may be very troublesome, if mostly outwards a characteristic external tumour appears and slowly extends. Anatomically the tumour is well encapsuled and divided into lobules by fibrous tissue trabeculæ; the substance is composed of translucent whitish or bluish gelatinous material, rather like a colloid cancer, which in the later stages may become almost liquid. The more malignant examples are more solid, firm, and opaque. Histologically the younger, more cellular areas have a solid epithelial aspect, alveolar in arrangement; in older parts the abundant cytoplasmic vacuolation produces the remarkable bladder-like physaliphorous cells and a sort of vacuolated syncytium, while the mucinous fluid which is formed at first cuts up the cells into columns and later forms a lake in which only a few scattered cells are visible. The microscopical structure is in this way rather various in different cases and in different parts of the same tumour, but it seems always to be recognisable. Prof. Stewart also deals shortly with the heterotopic notochordal tissue found about the dorsum sellæ—the "ecchordosis physaliphora spheno-occipitalis"—which is not so very rare if it is looked for, and which, with similar misplaced notochord in the sacral region, may possibly be the origin of chordoma. The paper gives a detailed account of the third example which has been met with in Leeds in recent years, and is followed by a description of an Edinburgh case by Drs. W. A. Alexander and J. W. Struthers. Others will doubtless turn up as the condition becomes more familiar.

## INDEX TO "THE LANCET," Vol. II., 1925.

The Index and Title-page to Vol. II., 1925, which was completed with the issue of Dec. 26th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of The Lancet, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

North Wales Mental Hospital.—The number of patients in the hospital is 1061. Of these, 935 are rate-aided cases, and the average weekly cost of maintenance during the past quarter was 19*s*. per head. The medical superintendent, Dr. Frank Jones, reports that the recovery-rate was maintained at a high level—51 per cent. for the last quarter, as against an average for similar institutions of 30 per cent.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLVIII.—THE TREATMENT OF SALPINGITIS.

### II.—CHRONIC SALPINGITIS.[1]

CHRONIC inflammation of the Fallopian tube, always associated with ovarian inflammation, may be of gonococcal, streptococcal, or tuberculous origin. Labour or abortion invariably precedes the streptococcal inflammations, but so long a time may have elapsed since pregnancy occurred that it is often overlooked as an ætiological factor. Whereas in the gonococcal cases a history of an acute attack some time previously is usually obtainable, in streptococcal cases this is usually not so, the course of the disease being insidious and chronic from the beginning. Tuberculous salpingo-oöphoritis is essentially a chronic condition, and only gives rise to acute exacerbations if secondary infection (usually of intestinal origin) occurs.

Whatever the organism may be, patients suffering from chronic salpingitis are semi-invalids, getting about with difficulty, always suffering from more or less pelvic pain, backache, dysmenorrhœa, menorrhagia, and especially dyspareunia. Examination usually reveals ill-defined pelvic swellings, on either side of or behind the uterus, having no characteristic shape, but invariably leading to more or less fixation of the uterus, which may be anteverted or retroverted. The fixation is a characteristic feature, and attempts to move the uterus in any direction always produce acute pain. This is perhaps the most important sign of chronic salpingo-oöphoritis. Tuberculous salpingitis can rarely be diagnosed clinically, unless it is associated with a general tuberculous peritonitis and ascites.

*Palliative Treatment.*

That many cases settle down and cease to cause important symptoms under palliative treatment is certain; for it is not uncommon, when operating for other diseases in women past middle age, to find tubes and ovaries fixed by adhesions, the former even containing pus, the result of a long obsolete salpingo-oöphoritis. The presence of pus in the tubes can rarely be diagnosed with certainty in essentially chronic cases, but where acute exacerbations occur—associated with fever, abdominal rigidity, and leucocytosis—pyosalpinx is probable. Even then the pus is invariably sterile, the acute exacerbations being due to secondary peritoneal infection via the intestine. Thus it happens that palliative treatment is often quite properly applied in cases even where the tubes may contain pus. Incidentally it may be remembered that intraperitoneal rupture of a chronic pyosalpinx is an exceedingly rare accident and its possibility may properly be disregarded. The reason for this is that a chronic pyosalpinx usually has very thick walls and is encapsuled by adhesions. Where a tuberculous origin is suspected—for example, in single women, in whom gonorrhœa can be excluded and pregnancy has never occurred—palliative treatment should not be adopted. The sooner a tuberculous tube is removed the better for the patient. The tuberculous inflammatory process has a great tendency to spread through the wall of the tube and to invade any adherent structure such as the small intestine or pelvic colon. If bowel is involved in the tuberculous process, removal of the tube always means damage to the bowel and subsequent rupture causing a fæcal fistula. Fæcal fistula follows removal of a long-standing tuberculous tube more often than any other operation, except that for a gangrenous appendix. The palliative treatment of salpingo-oöphoritis in general usually demands counter-irritation, and means directed towards the absorption of inflammatory products. Counter-irritation is best applied by vaginal applications of substances which have an affinity for water and set up a discharge from the cervix. In practice glycerine and ichthyol are the only substances of value. Glycerine may be applied to the vaginal roof on tampons of absorbent wool at night, whilst ichthyol is best used in the form of vaginal suppositories. Ichthyol, gr. xii., in cacao butter, gr. cxx., forms a convenient suppository. A hot plain water douche at 112° to 115° F. should first be given slowly so as to induce hyperæmia, and then the suppository passed up to the vaginal roof and left in all night. In the morning discharge and *débris* should be washed away with another plain water douche. Alternate nights for a fortnight is sufficient for this treatment, a week being allowed to elapse before repeating the course. If two courses of a fortnight do not produce decided relief from pain, it is generally useless to persist any further with palliative treatment. In combination with ichthyol treatment, radiant heat to the abdomen is often of great value. A home-made apparatus for this is easily contrived by making a cradle to cover the abdomen with two carbon filament electric lamps suspended in it. The amount of heat applied in this way can only be determined by experiment for each individual patient, since tolerance varies. The value of ultra-violet rays in these cases has yet to be determined, but it might be expected that benefit would ensue. X rays have been used and good results have been recorded. Given sufficient dosage to produce an effect, any benefit resulting is probably due to abolition of the ovarian functions and the sterilisation of the patient. Since most of these patients are already incurably sterile from closure of the tubes and disorganised ovaries, this is not a calamity. The abolition of menstruation might even be of advantage in that in most cases severe pre-menstrual pain occurs. On general grounds it is advisable that X rays should not be used in cases believed to be suffering from pyosalpinx, but should be reserved for non-suppurative lesions.

*Drugs* given internally have very little effect apart from the temporary relief of pain. Morphia, heroin, omnopon, nepenthe, in fact, any drugs containing opium derivatives, should be avoided owing to the danger of contracting a habit of taking them. Bromides are always valuable, whilst antispasmodic drugs like phenazone, especially combined with sal volatile, will often relieve pain. For menorrhagia it is best to rely on calcium lactate by the mouth, given in the form of a freshly prepared nascent solution. A mixture of pure lactic acid, gr. 200 by weight, with 75 gr. of precipitated chalk in ℥ viii. of chloroform water, gives a solution which contains 30 gr. to the ounce of calcium lactate; one ounce to be given every other night for a fortnight at a time.

*Operative Treatment.*

Although some of these cases will be permanently relieved by this treatment, the majority will prove intractable and operative treatment will have to be adopted sooner or later. This will always mean an abdominal section and removal of the affected organs. Conservative surgery must be adopted as far as possible to produce a symptomatic cure. In young women, where pre-menstrual pain is not complained of, a tube, ovary, or parts of them should be saved, if not too much damaged, in order that menstruation may be retained and the possibility of a future pregnancy not abolished. These operations are often very difficult and trying to the surgeon, but are rarely of great danger to the patient. As they are performed when active infection has disappeared, there is very little risk of general peritoneal infection even if a pyosalpinx is ruptured during removal, which, it must be admitted, is a common occurrence.

*The Risk of Damaging the Bowel.*—Very widespread adhesions will be encountered and the risk of damaging bowel during the separation of adhesions must always be borne in mind. Adhesions should be divided with the knife or scissors wherever possible, rather than

---

[1] An article on the Treatment of Acute Salpingitis by Mr. Stevens appeared in the previous issue of THE LANCET.

forcibly torn with the fingers. It is better to cut into the wall of a pyosalpinx and leave a fragment adhering to bowel than to risk opening the bowel by forcible separation of a firm adhesion. In tuberculous cases the risk of bowel injury is much greater than in any other type, and however carefully the operation is performed fæcal fistulæ will sometimes occur. In such cases the bowel may not actually be opened during the operation, but being infiltrated with tubercle may be so damaged that it perforates later. A fæcal fistula into the rectum or pelvic colon is not of so much importance, as it usually heals within two or three weeks, but a small intestine fistula is a tragedy as it may show no tendency to heal at all. When damage to the small intestine is recognised at the time, it is better to excise the damaged segment and do an end-to-end anastomosis or lateral anastomosis according to the situation of the lesion.

*Drainage.*—When the tubes contain pus and rupture occurs during removal the question of drainage has to be considered. If there is any doubt as to the infectivity of the pus the pelvis must be drained, preferably through a stab incision two inches away from the median incision, near the anterior superior iliac spine. In cases of long-standing in which the pus is certain to be sterile, drainage is unnecessary, but it is certain that in any doubtful case drainage makes for safety, and in general does no harm. As a rule 48 hours is sufficient for a large drainage-tube to be left in the pelvis, after which time it should be removed and a short length (half an inch longer than the thickness of the abdominal wall) of smaller tube substituted for another 48 hours.

*After-treatment.*—With regard to after-treatment I am convinced that early purgation prevents distension and makes for the comfort of the patient. Hence it is my custom to give calomel, gr. iii., in one dose 18 hours after the operation, a turpentine enema the evening of the day after the operation, and mistura sennæ composita, ℥iss., the evening of the second day after the operation. The calomel rarely produces an action of the bowels, but in general it starts peristalsis and prevents distension.

THOS. G. STEVENS, M.D., B.S. Lond., F.R.C.S. Eng.,
Obstetric Surgeon, St. Mary's Hospital; Gynæcological Surgeon, Hospital for Women, Soho-square.

## REPORT OF THE MEDICAL RESEARCH COUNCIL, 1924–25.

*(Concluded from p. 197.)*

### RESEARCH SCHEMES IN SPECIFIC SUBJECTS.

AMONG the special investigations being pursued we choose for notice here those whose main purport can be effectively summarised.

### *Problems of Child Life.*

In a series of over 500 infants examined by Dr. J. N. Cruickshank, Dr. J. Hewitt, and Dr. K. L. Couper at the Royal Maternity Hospital, Glasgow, it was found that neonatal death was due to disease or malformation of the child in about 16 per cent., to the complications of labour in about 33 per cent., and to maternal disease in about 50 per cent. of cases. The results of a report upon a series of 100 cases of toxæmia in pregnancy by the same workers indicate that in all forms of toxæmia in the second half of pregnancy there is disturbance of both kidney and liver functions, but the variations within each clinical group are so great that biochemical analyses of the kind made have given little help to prognosis for individuals. The most useful prognostic signs are found to be variations of the blood pressure and their relation to the degree of albuminuria present. The composition of milk in the early days of lactation is being studied by Miss Muriel Bond and Miss S. D. Widdows, working at the London School of Medicine for Women.

The collection of material towards the study of the causation of rheumatism in childhood, mentioned in previous reports, has been completed. Nearly 1000 cases have been examined from various sources, and the material is now being examined by Mrs. M. Forest Smith under the direction of Dr. John Brownlee. The results of an inquiry into the incidence of rickets among children under 2 years of age attending hospitals in London as out-patients will shortly be published. A consecutive series of children was examined at each of three hospitals, a radiograph of the wrist being taken in each case.

At the National Institute for Medical Research the mode of action of ultra-violet light in the prevention and cure of experimental rickets has been studied from several aspects by Mr. T. A. Webster. In confirmation of other workers he has found that practically any sterol-containing foodstuff can be rendered antirachitic by a suitable exposure to ultra-violet light.

### *Nutrition.*

Dr. S. S. Zilva is investigating the chemical properties of the antiscorbutic factor. He has also been superintending the preparation of large quantities of lemon-juice for the stores of the *Discovery* whaling expedition, using the knowledge he has gained of the stabilisation of the antiscorbutic factor. This juice is being tested periodically, and the results will be compared with those of clinical observations made by Dr. Marshall, the medical officer of the expedition. The unsaponifiable fraction from cod-liver oil has been investigated in detail by Dr. J. C. Drummond and others. Results appear to indicate that the active material is represented by not more than 10 per cent., and probably a good deal less, of the unsaponifiable fraction from the active oil. In other words, the quantity of active substance required to enable the young rat of approximately 100 g. in weight to grow is of the order of two millionths of a gramme per day. Dr. Drummond has collaborated during the past year with Dr. O. Rosenheim and Mr. Webster at the National Institute for Medical Research. A series of colour tests have been devised, which it is hoped will form the basis of colorimetric methods of assaying vitamin A value. Already it is possible to compare the value of a number of samples of cod-liver oil by this means in a few minutes and to obtain a result at least as accurate as that given by animal-feeding tests requiring a month or six weeks. The growth-promoting and antirachitic properties exhibited by previously deficient food-mixtures after exposure to the short wave-length radiations of the quartz-mercury-vapour lamp have also been studied, and the activation traced to an effect on the fats present in the food. The substance activated was present in the unsaponifiable fraction, and was found to be of the nature of a sterol. Experiments with highly purified preparations of cholesterol showed that this substance acquires powerful antirachitic properties, and in some cases growth-promoting action, after comparatively short exposure to ultra-violet radiations. The same discovery was announced almost simultaneously by Hess and also by Steenbock in America.

During the past year the Committee upon Quantitative Problems of Human Nutrition have continued to advise and assist both private and official investigators upon various matters within their terms of reference. The section dealing with the diets of agricultural labourers in a report published by Mr. A. B. Hill was supervised by the Committee, and assistance has been given to the Food Section of the Ministry of Health in a study of prison diets. Dr. Major Greenwood, the secretary of the Committee, has undertaken preliminary statistical work for a study of the physical and other characters of the school population which is under consideration by the Medical Department of the Ministry of Education. The Committee have been much impressed by the importance of a reassessment of the food-supply of the country comparable with but more extensive than that prepared for the Food (War) Committee of the Royal Society during the war. So soon as the data are available, the Committee will proceed with this investigation.

Two years ago work was begun in the medical unit of St. Thomas's Hospital under the direction of Prof. Hugh MacLean to ascertain what detrimental effect, if any, excessive protein diet exercised on renal function. Although medical writers are almost unanimous in declaring that high protein diet is harmful in kidney disease, yet it appeared that there is little sound evidence that this is so. Preliminary experiments gave irregular results. Ultimately it was found that the albuminuria and other evidence of renal damage claimed by various investigators to result from high protein feeding was apparently dependent on lack of vitamins or some other essential constituent of fresh food The extreme sensitiveness of the renal system to lack of vitamins was found to be striking, and it was considered probable that attention to this point might be of importance in the general treatment of nephritis.

### *Disorders of the Cardio-Vascular System.*

Under the direction of Sir Thomas Lewis at University College Hospital Medical School, Dr. A. N. Drury has made observations which throw an entirely fresh light upon the manner in which conduction deficiency displays itself in the auricular muscle. Cold, pressure, and increased acidity all depress the rate of conduction in auricular muscle and, if acting in sufficient degree, prevent the impulse from passing. These conduction defects are not due, as previously supposed, to change in the length of the refractory period, but to a phenomenon akin to that which has been described as "decrement" in nerve. The researches open up a new field of observation so far as cardiac muscle is concerned.

Miss E. P. Wolf has completed a series of observations upon local colour changes in skin deprived of its circulation, with particular reference to the nature of the red and white patches which then appear. She has confirmed Krogh's view that the red patches are due to leakage of blood into the skin through anastomoses with bone-vessels and that the white spots are influenced, but not solely, by temperature. Dr. B. Sacks has investigated the effects of intravenous injections of pituitary extracts in man. These act mainly on the capillaries and venules of the skin, producing intense paling of colour. The pallor is unaccompanied by more than a slight rise of blood pressure, but this slight rise is enough to distend the limb passively. It is probable that in man the pituitary body exerts its effects on the arterioles mainly in the visceral region. Dr. R. T. Grant and Sir Thomas Lewis have fully investigated the phenomenon called "reactive hyperæmia" in man. The hyperæmia is that which follows immediately upon the release of an occluded circulation. The reaction is independent of a nervous mechanism, central or local. It is thought to result from the accumulation of slowly diffusible substances, the products of chemical changes in the extravascular spaces. The mechanism is believed to be frequently or constantly in action in normal life and has much in common with that which locally controls the tissue circulation after injury and something in common with the vaso-dilatation which occurs in muscular exercise.

Dr. J. C. Bramwell and Dr. Sylvia K Hickson have been studying the mechanism of production of the Korotkow sounds in man by means of graphic methods. The results suggest a new hypothesis to account for the production of the Korotkow sounds, which seems to explain anomalies in the auscultatory criteria at present adopted for the clinical determination of diastolic pressure.

### *Disorders of the Excretory System.*

Dr. S. L. Baker, at the Middlesex Hospital, has described two cases of obstruction of the renal tubules caused by the excretion of hæmoglobin following the intravascular hæmolysis of transfused blood. Experiments have been made to determine the conditions under which hæmoglobin is excreted, and under which it is thrown out of solution in vitro. The results indicate that with the excretion of hæmoglobin in the glomerular transudate, which, like the blood plasma, is slightly alkaline, renal obstruction is due to the increase of the acidity and salt concentration in the tubules, which causes precipitation of the pigment probably in the form of hæmatin. This would explain the production of intrarenal obstruction in cases of the type described, and also in blackwater fever. A suggestion for the treatment of these conditions is accordingly the production of an alkaline diuresis.

The results of work by Dr. Mona Kirkhouse upon the effects of diuretic drugs show that drugs of this group, though very commonly used in current practice, are of little use in the treatment of dropsy due to nephritis, being unnecessary in mild cases and ineffective in severe ones. In œdema due to heart failure some diuretics can be used with advantage, digitalis for instance when the failure is due to auricular fibrillation, and drugs of the caffeine group when the heart rhythm is regular.

### *Mental Disorders.*

The composition of the committee dealing with this subject, in which the Council coöperate with the Board of Control, is as follows: Dr. Henry Head, F.R.S. (chairman), Dr. Thomas Beaton (secretary), Dr. C. H. Bond, Dr. Henry Devine, Prof. G. Elliot Smith, F.R.S., Sir Frederick W. Mott, F.R.S., and Prof. G. M. Robertson.

Miss L. Fildes continues to receive a whole-time grant for her work at Cambridge on mental defect. Investigations during the year have been directed mainly towards the study of those aspects of deficiency not primarily concerned with an actual lowering of intelligence, that is, towards impulsive and emotional mental factors

Dr. G. W. Pailthorpe, with the permission of the Prison Commissioners, has continued her studies of the psychology, health, and antecedents of women offenders in Holloway Prison. Dr. Philip Cloake, now working in Birmingham, is making an attempt to analyse the lethargic state and to show how this determines many of the mental sequelæ of encephalitis lethargica, while Dr. David Slight, at the University of Edinburgh, is studying the nature of the psycho-galvanic response and its use in the investigation of cases of mental disorder. The results gained from experimental work seem to confirm the belief that the response is essentially due to a change in the skin. Under the direction of Dr. F. Golla, at the Maudsley Hospital, London, Dr. Isabella M. Robertson has been investigating blood change in some conditions of insanity. In the research laboratory established under the direction of Sir Frederick Mott by the City and University of Birmingham, further studies have been made of the basal metabolism of mental patients, and upon variations in the iodine content of the thyroid gland and their possible correlation with mental and bodily conditions.

### *Tuberculosis.*

Work on the value of different oils in the treatment of tuberculosis is being continued by Dr. A. Stanley Griffiths. It has been found that animal oils are more germicidal than vegetable oils, and that the germicidal power of oils is increased by exposure to the sun's rays. Dr. A. C. Inman has made a series of further observations on the complement-fixation test, which bear out his previous conclusion that the test, when positive, is not an index of the activity of tuberculosis.

Preparations of sanocrysin received for testing purposes from Prof. Mollgaard were issued by the

Council for trial to the heads of university clinics in London, Edinburgh, and Cardiff, who are not engaged in private practice. An opinion, perhaps the only opinion, found to be common to the preliminary reports from all the observers was that the drug does exert a specific action on tuberculous tissues. Further clinical trials at other centres have been instituted, and are still in progress. Efforts made by Prof. S. Lyle Cummins to cure rabbits after virulent infection with bovine tubercle bacilli by subsequent treatment with sanocrysin have, so far, failed; nor has it been possible to reproduce in infected rabbits the phenomena of "shock" observed by Mollgaard in calves and by Secker and others in man. The conclusion drawn from experiments made by Sir Almroth Wright is that sanocrysin exerts no direct bactericidal effect upon the bacilli in human tuberculous lesions.

### *Filter-passing Viruses.*

Dr. M. H. Gordon, F.R.S., in the whole-time service of the Council and working at St. Bartholomew's Hospital, London, has continued his studies of the viruses of vaccinia and variola mentioned last year. Advantage was taken of the occurrence of various outbreaks of small-pox (variola) in different parts of the country. Comparison by strict serological methods showed that the viruses from five separate epidemics all gave positive reactions with antivaccinia serum. No difference in this respect could be found between virus from the mild type of small-pox sometimes called alastrim (or variola minor) and that from severe examples of this disease (variola major). Since comparable material from six outbreaks of chicken-pox and from other control sources has been found to give completely negative results with antivaccinia serum under the same conditions, there is good reason to believe that this serological method of identifying the presence of variola virus will give valuable aid in future in the diagnosis of small-pox, if it be used.

From a study of the immunity reactions of the virus of herpes, the main conclusions formed by Dr. J. R. Perdrau were that the virus of herpes is identical with the causal agent of encephalitis lethargica. The herpetic virus was demonstrated in the brain of the only fatal cases of encephalitis lethargica available, three in number. An antibody formed in response to inoculations of the herpetic virus has been found to neutralise in vitro comparatively large doses of the virus.

As to canine distemper, the arrangements at the farm laboratories of the Council for the breeding of a clean stock of dogs for experimental purposes continue to be satisfactory, and in the meantime many investigations have been carried out. The discovery has been made that ferrets can be conveniently used for much of the experimental work, subject to ultimate confirmation of the findings in crucial experiments with dogs. The extreme infectivity of the disease has been demonstrated, and there are strong indications of the transmission of air-borne infection, at least over short distances in an enclosed space.

### *The Biological Actions of Light.*

Prof. F. A. Lindemann, F.R.S., has accepted appointment as chairman of the committee investigating this subject in succession to the late Sir William Bayliss. Simple and accurate methods of measuring the energy of ultra-violet rays of different wave-lengths, whether in sunlight or from artificial sources, are being sought, and the therapeutic and other biological actions of light are being investigated. Dr. R. G. Bannerman, working at the Lord Mayor Treloar Hospital, Alton, is attempting to find means of measuring the clinical effects of light which might serve as a guide to the optimum dosage. Certain of his observations give fresh basis for the view that excessive dosage of light is harmful.

### *Anæsthetics.*

It is hoped in the near future to issue a schedule of simple tests which all samples of nitrous oxide issued for anæsthetic use should satisfy. It is recorded that after much difficulty, the commercial manufacture of ethylene has been taken up in England. Investigations of propylene, butylene, and acetylene are being pursued. Dr. A. J. Copeland, investigating less dangerous substitutes for cocaine for use in producing local anæsthesia, has shown that psicaine is unlikely to be useful for this purpose. With Mr. H. E. F. Notton he reached the conclusion that ethocaine borate, or "borocaine," is in many respects the ideal surface anæsthetic, and is of very low toxicity.

### *The Physiology of Vision.*

The Council have, after consultation with the Admiralty, the War Office, and the Air Ministry, appointed a committee to initiate and supervise researches in the physiology of vision, to coöperate with other Government departments, especially the Service departments, in studying problems involving questions of vision, and to encourage research in the subject generally. The personnel of the committee is as follows: Sir John H. Parsons, F.R.S. (chairman), Surgeon-Commander M. B. Macleod, Mr. F. C. Bartlett, Wing-Commander E. C. Clements, Major J. H. Gurley, Dr. H. Hartridge, Sir William Lister, Mr. J. W. T. Walsh, Mr. D. R. Wilson (secretary).

Dr. H. Hartridge and Mr. R. J. Lythgoe have completed a preliminary study of the effects of flicker on visual acuity and on peripheral perception of movement and are studying the effects of intensities of illumination upon visual acuity. During the coming year the committee propose also to investigate the effects of glare, and to initiate researches into the perception of movement, and the effects of fine industrial work on the eyesight. Miss Ida Mann is inquiring into the development and structure of the human lens with a view to explaining the phenomena observed by recent workers with the Gullstrand slit-lamp.

### *Experimental Epidemiology.*

In a first report upon the results gained in the study of long-continued experimental epidemics, by Prof. W. W. C. Topley and Dr. Major Greenwood, the data of experimental epidemics of pasteurellosis in mice, lasting for more than three years, are analysed and discussed. It has been shown that pasteurellosis will continue as a fatal infectious disease within a herd of mice for an indefinite period, exceeding at least three and a quarter years, or more than a complete generation speaking in terms of the normal lifetime of the mouse, on the sole condition that the population at risk is replenished by susceptible but non-infected animals. It is not true, so far at least as the animal and the infective organism studied are in question, that an infectious disease can be brought to a standstill in an infected community even by rigorous exclusion of infected immigrants. It is suggested that serious attempts should be made to find whether the observable data of herd sickness, naturally occurring in domestic or farm animals as well as in man, confirm or refute the teaching of this investigation. It is suggested further that this experimental work may give new guidance in the study and in the practical control of natural epidemics.

---

Post-graduate Courses in Berlin.—A series of international post-graduate courses is to be held in March in which the medical faculty of the University of Berlin will participate. The arrangements include courses in all the departments of medicine, particularly those of special interest at present: a two-weekly course on diagnostic and therapeutic technique, with practical work; a two weeks' course of clinical lectures in medicine; a one week's course on nervous diseases; a two weeks' course on the diseases of children; and a post-graduate course for ear, nose, and throat specialists. Further information can be obtained from the office of the International Post-Graduate Courses, Berlin, N.W. 6, Kaiserin Friedrich-Haus für das Ärztliche Fortbildungswesen, Luisenplatz 2/4.

# EDUCATION OF MYOPIC CHILDREN

## REPORT BY THE COUNCIL OF BRITISH OPHTHALMOLOGISTS

THE Council of British Ophthalmologists, which is a central standing committee of ophthalmological societies in the United Kingdom, has just issued a report [1] on the methods adopted in various parts of the British Isles for the education of children suffering from defective vision due to myopia or other causes (excluding the blind) For the purpose of this inquiry the Council has appointed Mr M S. Mayou (chairman) Dr W A. Anderson Mr N Bishop Harman, Mr R Beatson Hird, Dr J Kerr Mr G H Pooley, Dr W E F Thomson Mr O H. Walker, and Mr F A. Williamson Noble with the President, Mr E Treacher Collins and the hon secretary, Mr W H McMullen ex-officio Excluded from consideration were children who, on reaching adult life, would probably be economically blind, that is, 'unable to do work for which sight is essential," for in the opinion of the Council such children should be educated in schools for the blind

### *Special Educational Facilities*

The Council considers that special educational facilities are required for those who have defective vision, and for whom the ordinary school education is unsuitable—e g, cases of progressive myopia, defective vision due to corneal opacities, congenital abnormalities. Classes which give the required facilities exist, and are termed by the Board of Education schools for the partially blind." The Council thinks that this term is undesirable; it gives offence to parents and may leave a stigma detrimental to the child in after life The term ' myope class " is already in use, and connotes the purpose for which this form of education is designed Such classes were established by the London Educational Authority in 1908 It has been found that the best interests of these children are served if such classes are held in association with elementary schools, because the oral teaching and physical exercises given in the ordinary classes are available for the children. By this system association is fostered between the defective-sighted and normal children As the children in these classes are of various ages and educational standards individual teaching is essential, and therefore it has been found advisable to limit the number of children in each class The system of teaching by means of ' myope classes may seem to limit education so far as high scholastic attainment is concerned, but it has been found undesirable to encourage these children to follow a higher education, with the prospect of a sedentary occupation, thus incurring grave risks of serious breakdown later in life.

### *Existing Accommodation*

The Council has been informed that in London there are now 41 ' myope classes " providing accommodation for 015 children In the rest of England, according to the latest information available (Report of Board of Education, 1024, list 42), there are four myope schools,' and provision for other defective sighted children is made in special classes and in schools for the blind. With a view to obtaining further information a questionnaire was sent to ophthalmic surgeons practising in 76 areas of England, Scotland, and Wales, excluding London, with the following results —

*Question 1* — Are the school-children under the educational authorities of your district examined with regard to visual acuity, and those with defective sight systematically examined and treated by spectacles (when required) by a qualified ophthalmic surgeon?—*Results*: All children are examined with regard to visual acuity In nine areas no treatment is provided; in all others spectacles are ordered by an ophthalmic surgeon when required

*Question 2.*—The number of special schools for children with defective vision.—*Results*: Sixteen such schools or classes exist in nine areas.

*Question 3*—The number of classes for these children attached to (*a*) blind institutions, (*b*) ordinary elementary schools—*Results* Seven are located in blind institutions. Nine are some form of special class or school. No special school or class is provided in 07 areas.

*Question 4*—In country districts where there are not sufficient children to form a ' myope class," is any provision made for their education?—*Results*: In one area the children are sent to special educational centres. In two areas teachers are trained in the principles involved in the education o myopes and special desks, with blackboards attached, are provided. In one area special instruction is given to head teachers. *In one area all children with high or increasing* myopia are restricted in their work, the most seriously affected cases being excused school for varying periods the teachers being advised about the kind of work which is suitable for them on their return.

The Council realises that the inquiry has not been exhaustive but considers that it demonstrates that, with a few notable exceptions, the provision for the education of the affected children is seriously inadequate It is obvious that in country districts where the number of defective-sighted children is insufficient to form special classes some provision should be made either to send them to one of these classes in the nearest town or for their teachers to receive instruction in their management.

The Council strongly endorses the recommendation of the Departmental Committee on the Causes and Prevention of Blindness "that further provision should be made by education authorities for the education in myope classes or by similar methods for children with serious defects of vision requiring such facilities, and that steps should be taken to discover these cases at such an early age as will allow of preventive measures being adopted."

### *Recommendations*

The report concludes with the following recommendations of the Council —

(1) Children with defective sight should be examined periodically by an ophthalmic surgeon, who should prescribe the necessary treatment and educational régime

(2) In all large centres of population special classes should be established for children with such defective sight as renders them unsuitable for ordinary school education. These classes should be associated with the ordinary elementary schools, and limited to a nominal roll of 20 children to each class

(3) *In country districts where there are not sufficient* children to form a myope class,' instruction should be given to teachers and parents on the education and management of children with defective sight. Instructions for teachers and parents are contained in three pamphlets issued by the London County Council: (*a*) Hints for teachers of myope classes, (*b*) memorandum containing advice to parents of short-sighted children who have been recommended for admission to a myope class; (*c*) teaching of children recommended by the medical officer for "easy treatment" "oral teaching only," or to 'sit in the front row" Parents and local care committees should it is added, receive advice as to the choice of occupation for the children on leaving school.

---

ROYAL SOCIETY OF MEDICINE HONORARY FELLOWSHIPS.—At the last general meeting of the Fellows of the Society the following were elected to Honorary Fellowship Sir David Bruce, K C.B, F R.S. Sir Henry Morris, Bart. Dr Fritz de Quervain (Professor of Surgery, and Director of the Surgical Clinic University of Berne), Prof Camillo Golgi (Emeritus Professor of Histology, Royal University of Pavia), Geheim Med Rat. Prof. Dr Karl F J Sudhoff (Professor of the History of Medicine, University of Leipzig) Dr William James Mayo (Surgeon and Chief *of Staff*, the Mayo Clinic, Rochester, Minn., U.S.A.) and Dr Charles Horace Mayo (Professor of Surgery University of Minnesota, and the Mayo Clinic). Prof Golgi's death was announced shortly after the meeting.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *The Cultivation of Babies.*

ON account of his status as oldest member—he was born in 1844—Prof. Pinard again presided at the reassembly of the Chamber of Deputies. As a political representative he has never forgotten that he is primarily an obstetrician and a *puériculteur,* and in his address on the promised social reforms he did not fail to draw attention to those points which he considers vital—namely, the improvement of the French birth-rate both in quantity and quality and the reduction of infantile mortality. "And it must not be forgotten," he said, "that everything which separates a child from its mother makes it suffer—nay, more, endangers its life. Yet every year in Paris nearly 10,000 children are removed from their mothers only a few days after birth. In 1925 9349 children were put to nurse outside Paris. Is there anything more urgent than to rid our country at once of this social disgrace?"

The diminution in the French birth-rate, aggravated greatly during the middle period of the war, is now being reflected among children who have arrived at school age. In Paris the diminution in the number of children of the primary school grades is so obvious that it has been found necessary to reduce the teaching staff by 700. A serious effort is, however, being made to reduce infantile mortality. As an illustration may be mentioned a poster now displayed with official encouragement in bakeries and elsewhere which reads: "Mothers and Expectant Mothers! Do not forget that sickness and death among children are often due to parental ignorance. For securing normal development of your children, you should have them regularly examined by your physician. If you are unable to pay for such medical service, the free clinics and consultations are at your disposal."

### *The Oculo-Cardiac Reflex.*

Compression of the eyeball normally produces a slowing of 5–13 beats per minute in the cardiac rhythm, but this slowing is said not to occur in locomotor ataxia. The reflex is of some value, but may be obscured or rendered variable and inexact by failure to observe correct technique in eliciting and recording it. Largeau and Laignel-Lavastine have recently pointed out this source of error. They employ only digital compression, using the pulp of the thumbs. Compression should not be continued for more than 20 seconds, but the pulse should be noted for about a minute after compression has ceased, in order to detect variations which may still occur. Strict attention to this technique assures, according to the authors, uniformity in results, as proved by graphic registration made in a number of tests.

### *Toxic Foods at the Halles.*

Investigation of 24 cases of food poisoning in Paris in 1923 has shown that the causal organisms were all of the *suipestifer* (Salmonella) group, and that the infection was conveyed by contaminated cream and eggs. At the Halles, or great central market of Paris, food is supposed to be inspected, but this inspection service is really insufficient. A goodly proportion of food, moreover, is distributed in Paris without entry at the Halles. In 1922 30,000 cases of eggs escaped inspection. It has been found that dangerous infection is especially conveyed through the soiling often present on the shells of eggs.

### *Success of Tuberculosis Stamp Sale.*

The Christmas stamp sale of 10-centime tuberculosis stamps, tried in the Department of Meurthe-et Moselle by the French National Committee of Defence against Tuberculosis, has proved an immense success. More than 3 millions of the stamps sold secured the sum of about 300,000 francs to be devoted to anti-tuberculosis work in France. Henceforth the stamp sale will be conducted throughout France.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Workmen's Compensation.*

Mr. T. Hennessy, medical secretary of the Irish Medical Committee, has been giving interesting evidence before the departmental committee which is investigating the question of workmen's compensation. Dealing with treatment, he said that many injuries were inadequately treated owing to the want of facilities in every district. A medical practitioner of ordinary skill could not be considered to have the necessary knowledge to treat certain injuries by massage and electricity. Mr. Hennessy advocated training for workmen permanently disabled. Use might be made of institutions set up by the Ministry of Pensions, but no attempt should be made to dispense with the patient's own doctor. He recommended that disputes due to conflicting medical evidence should not be heard in open court, but should be submitted to a State medical referee, with a right of appeal to a board of medical referees. The State medical referee should be available for consultation if required by the injured person's doctor. He should also have power to enforce treatment after consultation with the injured person's own doctor, and to reduce benefit if treatment was refused. A medical assessor would not be necessary if this procedure were adopted, but should present arrangements hold, whereby disputed cases were heard in open court, then the medical assessor should be summoned in all cases where medical evidence was to be taken. The judge should not have the option of saying whether or not the medical assessor should be present. Mr. Hennessy believes that the difficulties of establishing a percentage scale of incapacity are very great, though the adoption of such a scheme might be possible in such specific instances as the loss of an eye or total or partial loss of a limb.

At a subsequent session of the departmental committee Dr. G. Pugin Meldon, certifying surgeon for Dublin City, suggested that there should be a probationary period for the medical examination of persons between the ages of 14 and 16, as it often happened that poor children who were badly housed and fed showed much improvement after being at work for some time. He inspected factories and examined all young people between 14 and 16, and his duty was to satisfy himself that they were suitable for the work they were doing and the work they would have to do later on. At present he had no power to re-examine them. He had also to decide that the work was suitable, and that they were not likely to be a source of danger or infection to other workers. All big factories had now first-aid squads amongst their workers, and he thought that every factory, no matter how small, should have a first-aid case, and that some of the workers should be taught the principles of first-aid.

### *Proposal for a State Medical Service.*

Prof. M. G. O'Malley, professor of surgery in University College, Galway, delivered a lecture recently before the Chamber of Commerce of Galway, in which he urged the establishment of a State medical service. He suggested that entrance to the service should be by competitive examination, and that the successful candidates should be graded according to their suitability. There should be compulsory retirement at the age of 65 and all members of the service should be whole-time officers. The hospitals should be under State control. Mr. O'Malley looked to "a gigantic scheme of insurance" to finance the scheme.

### *Experience for County Medical Officers.*

As has already been indicated in THE LANCET,[1] the Local Government Act, 1925, lays down that every county shall appoint district medical officers of health who must hold the D.P.H. or some corresponding degree. With a view to promoting the training of candidates with special knowledge the Rockefeller Foundation is sending three men to the U.S.A. to familiarise *themselves with the* latest developments of public health procedure there. It has been recognised that the position of the existing tuberculosis officers holding the D.P.H. is entitled to special consideration, and arrangements have been made with the Society of Medical Officers of Health to enable such officers seeking appointment as county medical officers to acquire further administrative experience. The society has selected suitable county areas where Irish medical officers can acquire experience of English methods of health administration, and the following nominees of the Department of Local Government and Public Health of the Irish Free State, who have been granted travelling Fellowships by the International Health Board of the Rockefeller Foundation, have already been attached to county health departments in England. Dr. Thomas Reynolds (Leitrim) to Shropshire; Dr. J. J. Dennehy (Waterford) to West Suffolk; Dr. T. P. O'Reilly (Cavan) to East Sussex; Dr. B. O'Beirne (Galway) to Lindsey (Lincs.); Dr. P. J. Burke (Sligo) to Wiltshire; and Dr. J. J. O'Connell (Tipperary) to Buckinghamshire. In addition to these official nominees Dr. G. Fitzgerald, of Tralee, has been attached to the East Berks U.S.D., and Dr. D. J. O'Regan (King's County) will shortly be attached to the West Sussex health department.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. T. T. Jeans is placed on the Retd. List with rank of Surg. Rear Admiral.

Surg.-Comdr. E. A. G. Wilkinson is placed on the Retd. List with rank of Surg.-Capt.

Surg. Lt.-Comdr. J. D. Bangay to be Surg.-Comdr.

D. Bell to be Surg.-Lt.

Surg.-Comdrs. F. L. Smith and R. H. McGiffen to *President*, addl., for the Medical Department of the Admiralty. W. H. Murray, to *Victory*, addl., for R.N. Hosp., Haslar, for specialist duties; G. R. McCowen and E. Moxon Browne, to *President*, addl., for three months' post-graduate course.

### ROYAL NAVAL VOLUNTEER RESERVE.

*Surg.-Comdr.* A. D. Cowburn is placed on the Retd. List with the rank of Surg.-Capt.

## ROYAL ARMY MEDICAL CORPS.

### ARMY RESERVE OF OFFICERS.

Lt. I. S. Thomson, late R.A.M.C., Def. Force, to be Lt.

### MILITIA.

Maj. J. C. Hall retires on attaining the age limit and retains the rank of Maj.

### TERRITORIAL ARMY.

Maj. R. G. *Badenoch resigns his* commission and retains his rank.

Capt. J. C. Andrews (late 9th Lond. R.) to be Lt. and relinquishes the rank of Capt.

Lt. R. S. Creed (late R.H.A., T.A.) to be Lt.

J. Cook to be Lt.

2nd Lt. R. J. P. McDowell (late R. Fus.) to be Lt.

*Sanitary Companies.*—F. W. Bury to be Lt.

## ROYAL AIR FORCE.

J. Magner is granted a short service commission as a Flying Officer for three years on the active list.

*West African Medical Staff.*—Dr. D. Duff, Medical Officer, Gold Coast, has been promoted to be a senior medical officer in that Colony in succession to Dr. H. W. Gush.

# Public Health Services.

## A PUBLIC MEDICAL SERVICE FOR LONDON.

COMPULSORY insurance at present by no means covers the medical needs of the poorer section of the community, for there is still a large class above the Poor-law level and yet unable to pay ordinary medical fees. *Mainly the dependants of insured persons,* they include also the families of those who do not come within the scope of the Insurance Acts. In some parts of the country these classes are provided for by clubs on contract lines or by provident dispensaries of various kinds. It is the persistent attempt in some places to perpetuate club practice in its less desirable forms, and the real demand in other places for medical attendance on a contract basis, as well as the delay in extending medical benefit to the dependants of insured persons, which accounts for the initiation of public medical services which are becoming quite common. The public medical service for London, projected by the Local Medical Committee, appears to be on the usual lines. It is based on voluntary contributions, the public are canvassed by salaried officers called collectors, who will enrol members and collect subscriptions of 3*d.* a head each week. The subscribers become eligible for treatment a fortnight after being enrolled. The services available are roughly the same as those under the medical benefit provision of the National Insurance scheme. Confinements and *special services* are excluded. Medicine is provided by the practitioners. There is an income limit of £250. Administrative expenses are to be met by an entrance fee of 1*s.*, and a quarterly charge of 9*d.* per member. In other words, 3*s.* out of the capitation fee of 13*s.* goes to the administration account. The scheme as set out will provide a basis for the extension of the medical benefit to dependants of insured persons, and will meet the demand on the part of friendly societies and others for contract service to the families of their members. Incidentally *it will remove from London practitioners any* temptation to take on cheap contract work. Whether the scheme as devised will meet these contingencies must depend upon the enthusiasm with which it is taken up. Its financial basis is voluntary, and success will wait on the ability of the collectors to persuade potential subscribers of the advantages to be gained by joining the service. The Essex scheme, run on similar lines, has certainly made good in the first two years of its existence. From the professional point of view, although the scheme may be a paying proposition, it will necessarily increase the work *of the already* busy practitioner. The experience of societies, such as the temperance organisations which have always had sections for children, shows that dependants are the most exacting members. To take over dispensing, as is suggested in the scheme, would further add to the work of the doctors. There is no reason to doubt that the coöperation of the chemists could be secured in providing medicines on lines similar to those of the insurance service. The projected service should then prove a boon to a large class of people who cannot pay doctors' bills, and who at present *crowd the* out-patient departments of our hospitals. The 300 or more practitioners who attended the recent meeting at the B.M.A. House appear to be keen on it. It remains to be seen whether the London public will realise the advantages of voluntary insurance *sufficiently to join in adequate* numbers.

## A GROWING SPECIALIST SERVICE.

In a report which has just appeared Dr. J. Middleton Martin states that increasing use is being made of the opportunities offered in Gloucestershire for treatment under the "Scheme for the Extension of Medical Services," and that the county council have been encouraged to enlarge its range. The advantages of the out-stations for the examination of children who live at long distances from the *general* hospital are being more and more appreciated. Arrangements have now been entered into with the Chepstow hospital and the cottage hospitals at Fairford and Winchcombe, and work will soon be begun at the new out-station at Soundwell. A table shows that during the last four years the work has increased in all directions, thus diminishing the average total cost per attendance. In 1921 the total cost per attendance was £1 13*s.* 6*d.*, the cost per case of specialist's services £1 18*s.* 6*d.*, the cost of medical officers per attendance 5*s.* 6½*d.* In 1924 the three items mentioned were reduced to 6*s.* 10½*d.*, 9*s.* 6½*d.*, and 1*s.* 11*d.* respectively; and it is expected that as the scheme develops there will be a further reduction. Requests for the opening of more out-stations have been received. The orthopædic service has been begun and will shortly be extended. Other services of almost any kind can be grafted on the scheme. The whole area of the county can be covered by the opening of 11 further out-stations in more or less populated areas and by the use of about 13 doctors' surgeries in the more sparsely populated parts of the county. The estimated capital expenditure for 1925 is between £6000 and £8000. The total maintenance expenditure for 1925 is £5050 and only exceeds the figure for 1924 by two-thirds, though it makes provision for an area more than twice as large. This last-named maintenance figure "works out at 2*d.* per head of the population in respect of rates per annum." The following are the details of the specialist services during the four years 1921–24: visits, 12, 45, 63, 80; cases seen 179, 705, 1091, 1485; operations 56, 159, 312, 412. There is therefore every indication of steady progress.

---

[1] THE LANCET, Jan. 2nd, p. 42

### The Control of Food and Drugs.

The report of the Salford public analyst, Mr. G. D. Elsdon, shows that there is at any rate one sanitary authority which administers with energy the Sale of Food and Drugs Acts. In proportion to the population the number of samples taken in Salford is high. Competition among food manufacturers is constantly bringing up new points, and Mr. Elsdon is of opinion that it is unfair for the local sanitary authority to be saddled with the cost of litigation to settle points which are of national importance. Many local authorities, he says, refrain from taking action, not because they think action in a particular case is undesirable, but because they are not prepared to face the possibility of protracted legal proceedings. To take a case to the House of Lords at a cost of £5000 would involve Salford in the equivalent of a 1*d.* rate. Mr. Elsdon thinks there should be some machinery by which the cost of necessary and desirable prosecutions should not fall entirely upon one local authority. The substance in the 1924 report which calls forth this suggestion is lemon cheese, and some of the facts given about this substance will serve to illustrate Mr. Elsdon's case. According to all cookery books lemon cheese should consist of sugar, butter, eggs, lemon-juice and rind, in the (approximate percentage) proportion of 54, 11, 25, and 10 respectively. Some manufacturers still make lemon cheese of this composition, while others sell cheap substitutes containing no eggs, but margarine, glucose, tartaric acid, &c. The defence is that the public would not buy an article if it were not palatable, but Mr. Elsdon's question is: Are manufacturers at liberty to describe an article by the name of some other article, merely because the flavours are similar and because the inferior substitute is not actively injurious to health? A good example is given of a shop-keeper who once had a large trade in lemon cheese made by herself according to a formula of Mrs. Beeton and labelled "home made." She now sells one of the cheaper substitutes which she purchases from a manufacturer, but still continues to label it "home made." Other points brought out in Mr. Elsdon's report are as follows:—

1. If a Salford milk purveyor collects his milk by motor from a Cheshire farm, the Salford authority has no power to take samples at the place of delivery.

2. Owing to the decision in Anness *v.* Grivell, margarine may still be sold under a fancy name. Thus the Salford authority took proceedings with regard to a sample described as margarine blended with butter which only contained ½ per cent. of butter fat. According to Section 8 of 1899 Act margarine may contain as much as 10 per cent. of butter but is still margarine. The decision in the case of Anness *v.* Grivell has therefore had an extraordinary effect.

3. Six out of 55 samples of Cheshire cheese were found to be adulterated, and Mr. Elsdon thinks it is probable that cheese imported from Holland and made from half-cream and three-quarter cream milk is sold as "Cheshire" cheese.

4. Eleven samples of diabetic foods were examined and contained in some cases over 60 per cent. of starch. A prosecution would probably have failed, because a booklet containing analyses was supplied at the time of sale. A diabetic flour of which the analysis corresponded almost entirely with an ordinary wheat flour was sold at 7*s.* 6*d.* for a bag containing 6 lb.

5. Peach-kernel oil was sold for almond oil in five cases out of 34.

6. Six out of 12 cases of paregoric contained no opium.

7. One sample labelled "blended turpentine excellent for household cleaning purposes, &c.," contained not more than 5 per cent. of turpentine.

It is gratifying to read in Mr. Elsdon's report that there is a great improvement in the efficiency of the dispensing service under the Insurance Acts, and that the use of arsenic in the ink of paper used for food wrapping has been discontinued. Throughout his report Mr. Elsdon stresses the fact that the Food Manufacturers' Federation, and reputable food manufacturers generally, wish to do the right thing, although there may be a difference of opinion as to what is the right thing. Better results might be obtained if a central authority such as the Food Commission had the whole matter entrusted to them and endeavoured in the first instance by coöperation with the traders concerned to come to some understanding as to the standards which should be adopted. The admittedly high standard reached in the American canned-meat trade may fairly be attributed to coöperation between the Government and the trading associations.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 16TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 341 (last week 255); scarlet fever, 1717; diphtheria, 991; enteric fever, 24; pneumonia, 1337 (last week 1761); puerperal fever, 63; cerebro-spinal fever, 6; acute poliomyelitis, 3; acute polio-encephalitis, 2; encephalitis lethargica, 67; dysentery, 5; ophthalmia neonatorum, 122. There were no cases of cholera, plague, or typhus notified during the week.

Of the 341 cases of small-pox, 60 (last week 25) were reported from the county of Derby, 57 of them from Derby C.B.; 143 (last week 140) from the county of Durham, 13 of these from Gateshead C.B., 4 from South Shields C.B., and 1 from Sunderland C.B., the large remainder widely scattered over urban and rural districts; 21 from the county of Northumberland; 16 from the county of Nottingham, 11 of these from Sutton-in-Ashfield; 2 from the county of Stafford (Stoke-on-Trent C.B.)—a new focus; 9 from the East Riding of Yorkshire (Kingston-upon-Hull); and 90 from the West Riding, 77 of which (last week 58) occurred in Rawmarsh.

*Deaths.*—In the aggregate of great towns, including London there were no deaths from enteric fever (an unusual and very gratifying event), none from small-pox, 94 (58) from measles, 14 (1) from scarlet fever, 59 (4) from whooping-cough, 31 (9) from diphtheria, 51 (18) from diarrhœa and enteritis under 2 years of age, and 81 (16) from influenza. The figures in parentheses give the numbers for London itself. The number of deaths from influenza is still diminishing, the figures for the last three weeks, working backwards, being 81, 114, 123.

New Whitehaven Hospital.—Princess Mary Viscountess Lascelles, accompanied by Lord Lascelles and Lord Lonsdale, opened the new Whitehaven and West Cumberland Infirmary on Jan. 22nd. Formerly the building was Whitehaven Castle, the seat of the Lowther family since the seventeenth century. It was purchased five years ago from the Lonsdale trustees and presented by an anonymous donor to the governors of the old infirmary for conversion into a modern hospital. In addition to this gift the donor gave £20,000 towards the necessary alterations, which cost £50,000.

"Audi alteram partem."

## THE STATUS OF THE CLINICAL PATHOLOGIST.

*To the Editor of* THE LANCET.

SIR,—The thanks of the private pathologist are due to you for your championship of his rights in the leading article on the County Pathological Service (THE LANCET, Jan. 16th). The progress of research in clinical pathology has opened up fresh fields of inquiry in the matter of diagnosis and treatment of disease, and a large number of medical men have specialised in this branch during the past 20 years. As the demand increased various institutions were established, and now this kind of work is being catered for by public health authorities, pathological departments of medical schools and hospitals, combinations or companies under the control of medical men, and business firms who employ qualified medical men. We are in a transition period, and as the demands for the pathologist's services increase year by year, some form of unification of centres will have to be made. But this centralisation may take a long time to establish, and in the meantime, in order to keep up and increase the standard of knowledge required of pathologists, their interests must be safeguarded. Otherwise the class of men and women entering this field of medicine will deteriorate. It cannot be expected that the best men and women will specialise in pathology if the prospect held out to them is only that of laboratory workers with a fixed salary and little, if any, chance of obtaining clinical experience. Whatever method of centralisation is established in the future, I hope the necessity of combining clinical medicine with pathology will be kept in the foreground, for the very essence of progress and advancement in pathological knowledge depends upon this combination. I am, Sir, yours faithfully,

Jan. 20th, 1926. E. H. SHAW.

## HEDONAL ANÆSTHESIA.

*To the Editor of* THE LANCET.

SIR,—In a paper in THE LANCET of Jan. 16th Dr. R. K. Lambert suggests, as a result of experiments on animals, that some of the aliphatic non-volatile compounds might be used as a preliminary to general anæsthesia, and more particularly he mentions a mixture of isopral and hedonal. For the last six months I have been using hedonal in this sense, given by the rectum about one hour before operation. The solution I use is 100 gr. of hedonal in 5 oz. of 33 per cent. alcohol. The enema is given by the nurse and in 15 minutes the patient is in a sound sleep and is quite unconscious of anything until some six hours after the operation is over. He remains asleep during transit to and from the theatre and knows nothing of the administration of the general anæsthetic, whatever it may be. Usually it is quite sufficient to give gas and oxygen. I have performed gastrectomy, colectomy, hysterectomy, and gall-bladder operations under this combination of anæsthetics, and have found the muscular relaxation greater than with the ordinary preliminary injection of morphia, &c., and subsequent ether. This relaxation is so marked a feature that I think the hedonal must have some special effect on the somatic, or more probably on the sympathetic, innervation of muscles.

I have taken blood pressure readings during operation, and because hedonal belongs to the urea series, I have made blood-urea estimations before and after operation, but neither of these has been found to follow any course differing from what is seen under the usual conditions of anæsthesia. My observations do not quite coincide with those of Dr. Lambert on animals, for I find that given by rectum there is only a very short period—namely, 15 minutes—before the patient is asleep. As might be expected, the effects are not quite uniform. In the human subject, for example, a big man requires more than a thin, wasted one, and though most of the patients sleep on for several hours after operation and need (or rather receive) careful attention to ensure that pressure sores shall not arise, others have been found to be unusually restive. I think this is merely a question of learning the right dose for the type of patient. Pulmonary complications are, if anything, less frequently seen than after the ordinary method of anæsthesia. Occasionally the patients have a few hours of inefficiency of the anal sphincter, which may render the giving of continuous rectal fluid impossible, but this soon passes off.

I should hesitate to give hedonal when the kidneys and liver are known to be functioning deficiently, but I do not know that it increases the risk in these conditions over the more usual methods. All my patients have expressed great satisfaction with the merciful unconsciousness of the pre-operative affairs, and from the surgeon's point of view the remarkable relaxation of muscles in abdominal operations is a great convenience. I think that post-operative flatulence is less evident, too, but I am not sure about this; it might be expected, however, as handling can be more gentle if the surgeon is unhampered by stiff muscles.

I am, Sir, yours faithfully,

Leeds, Jan. 20th, 1926. E. R. FLINT.

## DETERMINATION OF THE BASAL METABOLIC RATE.

*To the Editor of* THE LANCET.

SIR,—The interesting article by Mr. T. C. Hunt on the above subject in your last issue induces me to mention a very simple but not very accurate method which I have long employed. The determination of the basal metabolism has been chiefly employed in hyperthyroidism, and in this affection accuracy is not of much importance as a guide to treatment. Moreover, all the methods for determining the excretion of carbonic acid and the absorption of oxygen are very complicated and liable to many errors. I make the patient take two or three deep breaths to get rid of any excess of carbonic acid in the alveoli and then suspend the breathing in inspiration or expiration. When a patient who has fairly normal lungs can hold his breath for 30 or 40 seconds you can safely conclude that there is no excessive basal metabolism. I think the estimation of the excretion of the nitrogenous waste products through the kidneys is of more importance than that of the carbonic acid through the lungs.

I am, Sir, yours faithfully,

*Liverpool, Jan. 25th, 1926.* JAMES BARR.

## GLYCOSURIA AND LIFE ASSURANCE.

*To the Editor of* THE LANCET.

SIR,—Dr. Arthur Davies states that it is no part of the duty of the assurance company to spend time and incur expense, even with the applicants' approbation, on special examinations for determining the prognosis in cases of glycosuria. Surely this is a matter to be decided in each individual case. The benefits of assurance are derived not only by the policy-holders but also by the companies, and the latter often risk losing remunerative business by the rejection of glycosuric cases on insufficient evidence. The important point would appear to be that both the proposer and the company should know that more precise information may allow of acceptance, after which the extent of the sum to be involved under the policy will probably determine in whose interest it will be to pay the necessary costs of the laboratory examination.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 24th, 1926. T. IZOD BENNETT.

## IGNITION OF ETHER AT LOW TEMPERATURES.

*To the Editor of* The Lancet.

Sir,—The Joint Anæsthetics Committee of the Medical Research Council and the Royal Society of Medicine recently learnt from Prof. H. B. Dixon, F.R.S., that mixtures of ether vapour and oxygen would ignite at relatively low temperatures. Arrangements are being made for Prof. Dixon to carry out further researches into the ignition temperatures of various anæsthetic gases. but in view of the fatal accident which occurred in London some months ago, the Committee does not feel justified in delaying publication until this work is completed. Prof. Dixon has therefore sent me a preliminary report which I am instructed to make public.

It should be understood that this Committee does not wish to give an opinion as to the actual cause of the particular fatal accident referred to as it is without sufficient detailed information to warrant such a course. It must, however, be admitted that the metal tube of a dental dressing syringe used for drying purposes might easily be at a temperature above the danger point (200° C.) without such a possibility occurring to the mind of an operator unacquainted with the facts given below.

I am, Sir, yours faithfully,
Charles F. Hadfield, M.D.,
Hon Sec., Anæsthetics Committee.
London, W., Jan. 20th, 1926.

[The following passages are taken from Prof. Dixon's report to which Dr. Hadfield refers :—

"May I take the opportunity of urging the desirability, in the public interest, of issuing some warning as to the high inflammability of mixtures of ether with oxygen? It is curious how little information is given in text-books on the temperatures at which gases inflame, and there are some puzzling discrepancies between results that have been published in scientific journals. . . .

I have tested ether vapour by bringing it into heated oxygen through a silica tube equally heated, and have found a delayed ignition at 220° C. (428° F.)—a figure I believe to be too high (as a minimum ignition-point) rather than too low. Other observers have put the ignition-point of ether in oxygen as low as 100° C. (374° F.). A peculiar difficulty exists in the determination of the ignition-point of ether mixtures, because the vapour itself decomposes rather rapidly in contact with heated surfaces, and secondly, because the mixture may undergo a partial combustion with an almost invisible flame, and this may develop into the normal luminous combustion. The late Sir William Perkin found that ether vapour began to show this incomplete burning in air at 260° C., and Mr. A. G. White, of Messrs. Nobel's Explosives Co., has observed a "cool flame" to start under certain conditions below 190° C. Now the normal ignition of the most inflammable mixture of ether and air has been found by several observers to occur about 360° C.—the ignition not being violent. But ether and oxygen form highly explosive mixtures in which the detonation-wave may be rapidly set up once the flame is started. The lowest ignition-point of such ether-oxygen mixtures has yet to be determined precisely, but it is obvious that there is a special danger in bringing a heated body in contact with such mixtures. That the heated body is not visible red-hot is no guarantee of safety; the danger-point begins at least 300° C. below visible redness."]

## "DAILY MAIL" HOSPITAL BALLOT.

*To the Editor of* The Lancet.

Sir,—In your issue of Jan. 2nd you report that the British Charities Association, of which I happen to be president, "allocated last year £15,000 and this year £20,000 to the London Hospital." No such luck! though I have little doubt that you will yourselves make up for the printer's error. The B.C.A makes no grants direct to any London hospital. The money allocated to London hospitals—note the "s"—is paid to the King's Fund, who distribute it as they think fit.

I am, Sir, yours faithfully,
Knutsford,
Chairman, London Hospital.
Jan. 22nd, 1926.

---

## GOLD SALTS IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

*To the Editor of* The Lancet.

Sir,—In his contribution to the discussion on the Treatment of Pulmonary Tuberculosis with Sanocrysin at the Royal Society of Medicine on Jan. 12th, Prof. T. R. Elliott mentions (The Lancet, Jan. 16th, p. 126) that sanocrysin is a soluble thiosulphate of sodium and gold. I should like to remind your readers that over eight years ago Mr. Henri Spahlinger, acting on the suggestion of the late Dr. Arthur Latham, used gold as well as bismuth and other mineral salts in the treatment of tuberculosis, publishing his results in the *Revue Médicale Suisse* of December, 1917. Mr. Spahlinger summed up his experience in the sentence: "So long as the doctor has not at his disposal a series of different bactericidal salts which will penetrate to the centre of the lesion, chemotherapy will be powerless to cure somewhat advanced tuberculosis."

I am, Sir, yours faithfully,
Bruce Bruce-Porter.
Grosvenor-street, W., Jan. 15th, 1926.

---

## INTRA-URETHRAL NEGATIVE PRESSURE DURING COITUS.

*To the Editor of* The Lancet.

Sir,—Mr. Wansey Bayly quotes, and agrees with, Mr. Charles Gibbs's statement that "the meatus opens in the introducing movement . . . ." But is this so? I suggest *only in the absence of the frenum.* Examination of the frenum and its attachments will, I think, readily show that "the introducing movement," when engagement with the vaginal wall occurs, must exert traction on the frenum and draw tightly together the lips of the meatus, firmly closing it. There happens a close engagement of the frenum region of the penis with the vaginal wall. One proof of this is the fact that the V.D. clinic M.O. sees torn frenums noticed by the patient immediately after coitus. In a clinic for seafarers, such as the writer's, the complaint that "the bobstay has carried away" is not very rare. In no case has the patient with torn frenum admitted that the union had been with a virgin, or intromission difficult.

That the gonococcus is somehow deposited on the surface of the male urethra, remains there for a time, and spreads first along that surface, has always been nothing but a careless assumption. It receives no support from the mechanics of sexual congress as here suggested; nor from the common experience that the first few days' tingling thin discharge of an early case, though repeatedly examined with care, seldom indeed reveals any gonococci. As a rule these are found only later when the discharge has become macroscopically purulent. Were it mainly, or even at all, a surface infection, should not the bacterium be found readily from the start? Mr. Kenneth Walker has shown that in the male urethra the deeper lymphatic spread can at least outstrip the superficial original implantation.

I suggest that one thing appears as certain in gonococcal infection of the male urethra—viz., that it is from the very first an infection of the deeper lymphatics of the mucous membrane, and beyond the immediate reach of antiseptics.

I am, Sir, yours faithfully,
H. M. Hanschell.
Albert Dock Hospital, Connaught-road, E., Jan. 22nd, 1926.

---

*To the Editor of* The Lancet.

Sir,—Mr. Wansey Bayly's letter is interesting to me as I have been one of those who put forward the argument that septic material is carried down the male urethra during coitus by means of a suction action (*Practitioner*, February, 1922). Mr. Bayly's comparison to the piston and cylinder is erroneous. The head of a metallic piston is not a living organ nor is it possessed of muscular action. The *rigid* penis may resemble a piston, but fortunately a penis possesses a contractile power of its own; thus, during coitus there is the body working the piston and the piston undergoing rhythmical contractions. Female hormones are undoubtedly absorbed by the male urethra during intercourse, why not infected material?

I am, Sir, yours faithfully,
M. W. BROWDY.
Harley street, W., Jan. 22nd, 1926

## AN EASY METHOD OF PERFORMING TRACHEOTOMY.

*To the Editor of* THE LANCET.

SIR,—Some 15 years ago I performed tracheotomy in an adult on lines very similar to those described by Prof. Kenelm H. Digby in the LANCET of Jan. 16th. The trachea was obscured by an unusually wide thyroid isthmus which was clamped on each side with long-bladed forceps, and then divided. The operation, as stated by Prof. Digby, was simple and almost bloodless.

I am, Sir, yours faithfully,
C. HAMILTON WHITEFORD.
Plymouth, Jan. 21st, 1926

## PRIVATE NURSING HOMES.

*To the Editor of* THE LANCET.

SIR,—Is it not most desirable that consultants and general practitioners, before recommending patients to a private nursing home, should invariably have a good knowledge of the home, as regards the nursing staff and the food; and that patients or their relatives should make more careful inquiries on these points than is usually the case?

Pay wards in a hospital are under the control of a responsible hospital board; but private nursing homes are usually not under the control of any such responsible body. Of course, most private nursing homes are good, or fairly satisfactory; but not all. When we think of those we have loved and lost, it is most distressing to know that the last weeks of their lives were made miserable by the unkind and unsympathetic treatment of the nurses, and by the bad food in a private and expensive nursing home. Worse defects I do not desire to discuss.

I have ventured to write this letter owing to my own sad experience, and the experiences related to me by numerous reliable friends. Also it is desirable that disrespect for the medical profession should not be tolerated in any private nursing home. Recently the lady director of a large and well-known private nursing home in London calmly informed me (without any provocation) that most medical men were not straight, and were more suitable for tram-drivers than doctors, and that nurses were badly and unfairly treated by medical men. As general statements these remarks are, of course, untrue and unfair.

I was also informed at this home that patients were ungrateful. I have the diary of a patient who recently died as the result of treatment in this nursing home; and it is very painful reading indeed. I can understand that for the nursing and treatment in such a home patients cannot feel grateful

I am, Sir, yours faithfully,
M.D., F.R.C.P.
London, Jan. 26th, 1926

⁂ Private nursing homes vary from the good to the inadequate and—judging from communications we have received at different times—even to the bad. It is certainly right that the doctor in charge of the case should be responsible for the diet, and his inquiries as to the possibility of the home supplying the diet ordered in proper substance and in proper manner would be accepted in well-run nursing homes as perfectly reasonable. Where a consultant is in question, the home having been selected by the doctor in charge of the case, the support of the consultant should be insisted upon. Where the consultant is responsible for the choice of the home, he should in every case listen to representations of faults, either in diet or service. We are aware of difficult and delicate situations which may arise, while we are also well aware that the stories of large profits made by private institutions have been very generally baseless. —ED. L.

## ORGANOTHERAPY IN SEXUAL PERVERSION.

*To the Editor of* THE LANCET.

SIR,—In your annotation concerning sexual offences against young persons (THE LANCET, Jan. 2nd) you draw attention, rightly it seems, to the absence of mental defect as a cause. In this age of organotherapy it might be well to consider the possibility of other causative defect than a mental one in these cases of sexual abnormality and in other forms of sexual perversion. It is quite conceivable that deviation from the normal sexual impulses is connected with hormone lack. Two French physicians, L.-M. Pierra and A. Jouve,[1] claim to have effected good results in sexually abnormal females by spermatotherapy, injection of orchitic extract of the spermatogenic portion of the gland. If this be so, then possibly ovarian extract would have a similar effect on male perverts. The victims of abnormal sexual desires might be induced to disclose themselves were there a prospect of treatment by other than punitive methods.

I am, Sir, yours faithfully,
D. T. BARRY.
Physiological Department, University College, Cork,
Jan. 19th, 1926

## PROFESSIONAL CRITICISM OF THE GENERAL MEDICAL COUNCIL.

*To the Editor of* THE LANCET.

SIR,—It seems to me that the present criticism of the General Medical Council in the public press at home is not due to any lack of appreciation by the public of the need of such a body to prevent the growth of abuses which would inevitably arise were the Council non existent, but to the methods of its judgments. It is one of our national characteristics to regard with suspicion the decisions of tribunals empowered to pronounce summary judgments without appeal, and for this reason those of a professional tribunal like the General Medical Council which can to all intents and purposes determine without appeal the career of a professional colleague are particularly suspect. I have been in the habit for many years of reading the proceedings of the Council as reported in THE LANCET, and am convinced that its decisions are almost invariably both just and tempered with mercy. Nevertheless I am in agreement with the great majority of my fellow countrymen who resent the practical absence of appeal from the judgments of the Council. The General Medical Council being under the Privy Council, any practitioner struck off the Register has, it would appear, the right of appeal to the Privy Council itself. This being so I would suggest that it should be arranged that in future such appeals should be referred for consideration by the Privy Council to its Judicial Committee—that very illustrious body which is the highest court of judicature in the Empire. Were this done public opinion would be reassured and much irrelevant criticism of the Council obviated.

I am, Sir, yours faithfully,
HINDUSTAN.
Bengal, India, Jan. 7th, 1926.

⁂ Our correspondent may not have seen a recent leading article in THE LANCET setting out the legal position. There seems no doubt that the Judicial Committee of the Privy Council would not act in the way suggested; the actual question of their doing so has been raised before.—ED. L.

---

[1] Journal de Médecine de Bordeaux, 1925, p. 101.

## THYROID GLAND AND CALCIUM THERAPY

*To the Editor of* THE LANCET.

SIR,—In your issue of Jan. 9th appears a letter from Dr. D. C. Nasmyth which raises a point of great clinical importance—namely, the advisability of administering thyroid substance to individuals suffering from chilblains. Dr. Nasmyth contends that any benefit which results from such treatment is due to the contained parathyroid element, and that, in her experience, the "administration of thyroid often causes chilblains where they have not previously existed."

There is, I think, ample evidence that the salts of calcium are of great value in the treatment of chilblains, and the work of Groves and Vines showed that the parathyroid apparatus and the calcium metabolism of the body stand in close relationship. In the experiments of MacCallum and Voegtlin on the effects of calcium salts on tetany, they showed that both in animals and human beings the administration of lime salts caused the symptoms to disappear. The exhibition of calcium salts in the treatment of chilblains dates back to days before the rôle of the parathyroids was understood. It is now, in conjunction with parathyroid substance, an accepted method of treating this troublesome, if somewhat petty, complaint. That many sufferers from chilblains are also hypo-parathyroideics is probable; it is also likely that some of these individuals are lacking an adequate supply of thyroid secretion, and they would therefore benefit by thyroid feeding.

The whole question of the inter-relationship of the thyroid and parathyroid apparatus is still so undecided that, clinically, it is only possible to pick out the outstanding symptoms in an individual case and prescribe accordingly. I do not see any good grounds for objecting to the dual prescription of thyroid and parathyroid in a given case, so long as the symptoms support such a prescription. I cannot personally recall any patients who have developed chilblains for the first time after taking thyroid substance; but it is not improbable that this might occur in what may be called "potential" sufferers, if their calcium elimination was briskly stimulated.

I am, Sir, yours faithfully,
IVO GEIKIE COBB.
Queen Anne street, W., Jan. 12th, 1926.

## CHARING CROSS HOSPITAL INSTITUTE OF PATHOLOGY.

*To the Editor of* THE LANCET.

SIR,—In your issue of Nov. 22nd, 1924 (p. 1102), you published details of a scheme under which the Hospital for Epilepsy and Paralysis placed its pathological facilities at the disposal of general practitioners in the neighbourhood, for the benefit of those patients who could not pay private fees, and in the same issue (p. 1097) a letter signed by the pathologists of three London hospitals, of whom Dr. Alfred Piney was one, protesting against the hospital's policy. Their argument was carried on by Dr. J. A. Murray, President of the Pathological Section of the Royal Society of Medicine, and you were good enough to publish a reply from the hospital on Dec. 6th (p. 1206).

A circular dated Nov. 1st, 1925, from Charing Cross Hospital Institute of Pathology has reached me, from which it appears that this hospital's scheme, which was criticised a year before, has been in the main adopted by the Institute. In an accompanying schedule of fees the statement is made that Dr. Alfred Piney (one of the signatories of the above-mentioned letter) will sign all reports, and I venture to ask, through your columns, if Dr. Piney will state what has influenced him during the past 12 months to change his views, and whether his present opinions are shared by his co-signatories.

I am, Sir, yours faithfully,
H. W. BURLEIGH,
Secretary and General Superintendent, Hospital for Epilepsy and Paralysis.
Jan. 25th, 1926.

## THE SPECIAL DIPLOMAS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

*To the Editor of* THE LANCET.

SIR,—The younger generation can now obtain diplomas in otology, ophthalmology, and other subjects at the Royal College of Surgeons of England as an evidence of their competence to practise these branches of their profession as "specialists." This is a step in the right direction, but to senior men it may seem hard that, after years of hard work, they should be without such a special diploma unless they pass the necessary examination. Many men hesitate, lest failure should occur to prejudice them in the eyes of their patients. They feel that such an examination would be at the hands of their contemporaries, possibly even of their juniors, and that differences of personal opinion might hazard their success. Would it not be an expedient and graceful act if the Royal College could see its way to granting its special diplomas to those who have been practising their specialties for, say, 25 years? Of course, on payment of the necessary fee.

I am, Sir, yours faithfully,
F.R.C.S. AND SPECIALIST OF THIRTY YEARS STANDING.
Jan. 22nd, 1926.

⁂ Our correspondent, whose position as a specialist requires no strengthening, puts forward a view that must command sympathy, but we believe that the College would decline the responsibility suggested. The task of discrimination would be too difficult because there are no standards on which the withholding the diploma without examination from claimants to the position of specialist could be justified, at any rate, in the eyes of the disappointed. And injustice might be done unwittingly.—ED. L.

# Obituary.

## IRIS FOX, M.D. LOND.

WE deeply regret to record the death of Dr. Iris Fox from septicæmia. She pricked her finger at an autopsy on an accident case on Christmas Eve and this was followed by severe local infection, which it was hoped for several weeks would not become generalised. Her death occurred on Jan. 21st.

Iris Fox was the youngest daughter of Dr. R. Fortescue Fox and was born at Strathpeffer Spa, of the sixth medical generation in direct line of the Fox family. She was educated at Queen's College, Harley-street, and the Mount School, York, and then studied for two years at the Slade School of Art before entering the London School of Medicine for Women with a scholarship. After qualifying in 1915 she held a series of resident appointments at the Royal Northern Hospital, the South-Western Fever Hospital, and the South London Hospital for Women. Towards the end of the war she spent some months at Samoëns, in French Savoy, in charge of women and children *sinistrées*, sent there by the Friends' War Victims' Committee. In 1918 she became medical registrar at the Royal Free Hospital before definitely taking up the pathological work which was to become her chief interest in medicine. After 18 months as second assistant pathologist at St. Mary's Hospital and a further year as assistant pathologist at the Swansea General Hospital, Dr. Iris Fox was appointed senior assistant pathologist at the Royal Free Hospital, which carried with it the assistant directorship of pathological studies in the London School of Medicine for Women. Just before doing so she took the M.D. Lond. with pathology as the special subject, and worked for some months on endocrine glands in relation to mental disorder, at the Maudsley Hospital, under the guidance of Sir Frederick Mott. Her time at the Royal Free Hospital was largely spent in organising an efficient bacteriological department, what remained being devoted to a study of the streptococci, especially in relation to infective arthritis, which she was about to collate and prepare for publication at the time of her death. "The fact that so little of her work has seen the light was due," writes one of her colleagues, "to a confirmed habit of careful preparation and a certain diffidence of mind. The years spent in clinical work before her specialising in pathology had given her experience and a sense of proportion, and she was laying the foundations for really useful bacteriological investigation. In the earlier years of her work pathology had to compete for the mastery of her mind with books, people, and the countryside. Her friends never felt it necessary to remember her scientific attainments, for she was essentially an artist, and though a feeling that she lacked technical ability led her to abandon painting as a profession she had the best of taste in literature and art."

We hope that it may prove possible still to publish the work on the *streptococci, to the study of* which Dr. Iris Fox had devoted the best years of her life and to which by a melancholy coincidence her early death was due.

## JOHN ASTLEY BLOXAM, F.R.C.S. Eng.

Mr. J. A. Bloxam, who died on Jan. 12th at the age of 82, was a surgeon of the old school, who gained a considerable reputation in plastic surgery. As a student at St. Bartholomew's Hospital he was a pupil of Sir James Paget, and after qualification as M.R.C.S. Eng. in 1864, was so fortunate as to be appointed house surgeon—and later private assistant—to that great man. Becoming F.R.C.S. in 1871, he acted for a time as assistant surgeon to the Royal Horse Guards (Blue), and when he left the Service, which gave him hardly enough scope for his talents as an operator, was appointed surgical registrar at St. Bartholomew's. In 1873 he became assistant surgeon to Charing Cross Hospital, and for more than 30 years gave devoted service to this institution and its medical school.

Mr. Bloxam's remarkable dexterity and neatness made him an excellent plastic surgeon. His methods, so far as antiseptic or aseptic technique were concerned, *might be conservative, but his results were remarkably* good, and it has been regretted that a man with such gifts for general surgery should have early specialised in venereal disease. The repair of tertiary syphilitic destruction, however, gave him many opportunities for exercising his ingenuity. The transplantation of part of a finger to form the basis of a new nose was one of his successes, and created a sensation at a time when plastic surgery was hardly even in its infancy. In course of time Mr. Bloxam became senior surgeon to Charing Cross Hospital and was also senior surgeon to the London Lock Hospital. Although he regarded himself as a disciplinarian he had the kindest of hearts and made very many friends. On his retirement to Bourne End, Buckinghamshire, where he inherited a small estate, he took a prominent part in the public life of the district, and was a justice of the peace and chairman of the Little Marlow Parish Council. For recreation he took delight in fishing and shooting.

Mr. Bloxam was a Knight of Grace of the Order of St. John of Jerusalem. He is survived by his wife, a son, and two daughters.

The Educational Health and Food Campaign.—This campaign was inaugurated in 1907 and has since been carried on with the help of numerous medical, philanthropic and other bodies. The intention of the organisers has been to spread information on how to keep healthy and on the choice and preparation of food. No special system of diet has been advocated, but attention has been directed to those foods which nourish best at least cost; the value of finely-ground wholemeal bread has been emphasised. At the request of the Bread and Food Reform League the campaign is now being continued by the People's League of Health. Funds are urgently needed to fight the widespread ignorance of the public. Local health authorities are being urged to arrange meetings and to publish and distribute educational pamphlets. The signatories of the appeal, issued from 12, Stratford-place, London, W. 1, include many distinguished medical men. Subscriptions may be sent to the hon. organiser.

# Medical News.

University of Oxford.—The Rolleston Memorial Prize, which is now worth about £100, will be awarded in the Trinity term for a memoir of original research in animal or vegetable morphology, physiology, pathology, or anthropology. The prize is open to Bachelors in Arts or Medicine at Oxford and Cambridge within six years of graduation and ten years *of matriculation, and also to certain others* who have been candidates for such graduation or for the B.Sc. at Oxford. Work already published is admitted to the competition, and candidates must forward their memoirs to the Registrar of the University of Oxford before March 31st next.

University of London.—A course of six lectures on the Physiology of Muscle will be given by Prof. A. V. Hill at University College, Gower-street, W.C., at 5 p.m., on *Monday, Feb. 1st,* and *on the following Mondays.* Admission will be free without ticket.

*University College Hospital.*—A series of four lectures on the History of Medicine, illustrated by lantern slides, will be delivered at University College Hospital Medical School by Dr. Charles Singer, on Thursday, Feb. 4th, and the three following Thursdays, at 4.15 p.m. The subjects of the lectures will be the History of Malaria, of Gout and Diabetes, of Rickets, and of Small-pox; they will be open to medical students.

Territorial Army Medical Officers' Association.—Medical officers, both active and retired, are reminded that the first annual dinner will be held on Friday, Feb. 12th, at 8 p.m. in the Café Royal, 68, Regent-street, W. Many distinguished guests are expected. Tickets may be obtained from Colonel M. B. Ray, D.S.O., M.D., at 37, Russell-square, London, W.C. 1.

Fellowship of Medicine and Post-Graduate Medical Association.—Dr. J. W. McNee will lecture for the Fellowship, on the Treatment of Renal Disease, on Feb. 4th, at 5 p.m., in the lecture hall of the Medical Society, 11, Chandos-street, London, W. A comprehensive course in Venereal Diseases begins at the London Lock Hospital on Feb. 1st and will continue throughout the month. From Feb. 8th to 27th a combined course in Diseases of Children will be given by the Paddington Green Hospital, Victoria Hospital, and the Children's Clinic. There will be morning and afternoon sessions in all *departments of the hospitals.* For the convenience of the general practitioner, the London Temperance Hospital has arranged to hold an evening course from Feb. 8th to 19th. A general intensive course in medicine, surgery, and the specialties will take place at the *Queen Mary's Hospital, Stratford,* from Feb. 15th to 27th. Daily sessions will be given at 10.30 a.m. to 5 p.m., including demonstrations of clinical methods and groups of illustrative cases. The following courses will be held in March: Medicine, Surgery, and the Specialties at the Hampstead Hospital (for the general practitioner); Bacteriology, Westminster Hospital; Diseases of the Chest, Brompton; Gynæcology, Chelsea Hospital for Women; Ophthalmology, Royal Eye Hospital; and Tropical Medicine at the London School of Tropical Medicine. All the syllabuses and the General Course programme, which also appear in the *Post-Graduate Medical Journal*, may be had on application to the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

James Mackenzie Institute for Clinical Research, St. Andrews.—On Jan. 10th Prof. David Waterston resumed his consideration of Mackenzie's position in regard to general medicine. In his earlier works a provisional classification of symptoms into structural, functional, and reflex was adopted, the term reflex being limited to such manifestations as the viscero-motor and viscero-sensory reflexes. But in his later work he pointed out that the functional activity of each organ is regulated and controlled so that it is adapted to the needs *of the whole* body from moment to moment, and that this regulation is effected by reflex activity. He therefore included functional symptoms in the class reflex. The view put forward that the majority of symptoms, other than structural, are due to the disturbance of normal reflexes *is of the* greatest value to clinical medicine. It draws attention to the fact that symptoms are end-results, and that for their proper investigation it is essential that the intermediate processes concerned in their production be detected. A particular symptom *such as breathlessness may* occur as a normal event, as a result of experiment, as the result of administration of a drug, or in disease. The process concerned is, however, the same in each case. The basis of medicine must therefore be a knowledge of the processes by which organs are regulated.

RONTGEN SOCIETY.—A meeting will be held on Tuesday, Feb. 2nd, at 32, Welbeck-street, London, W., at 8.15 P.M., when R. J. McCallum Tozer will read a paper on a Gas Tube with Variable Penetrating Power, and M. A. Codd will describe a New Regulator for a Gas Tube.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—A concert will be given by the Stock Exchange Male Voice Choir at the Wigmore Hall on Feb. 23rd, at 8.15 P.M., in aid of the Guild. The Choir will be assisted by Miss Dorothy Silk, Miss Margaret Fairless, Miss Kathleen Markwell, and Mr. Norman Stone, and a very attractive programme has been arranged. Tickets, from 10*s.* 0*d.* to 2*s.* 6*d.*, may be obtained from the secretary of the Choir, Stock Exchange, E.C. 2, or at the Wigmore Hall.

PRESENTATION TO PROF. RUTHERFORD MORISON.—On Jan. 21st a portrait of Prof. Morison was presented to him at Newcastle in recognition of his great services to British surgery. We are asked to state that any subscribers wishing to have a photogravure should apply immediately to Mr. R. J. Willan, 6, Kensington-terrace, Newcastle-on-Tyne, as copies will shortly be unobtainable. On page 265 is described a Russian modification of the bipp method of treating infected wounds which Prof. Morison introduced in 1916.

THE CHILD OF SCHOOL AGE.—A series of lectures on the Health of the Child of School Age is to be delivered under the auspices of the Institute of Hygiene at 28, Portland-place, London, W., on Wednesdays from Feb. 10th to April 21st, at 3.30 P.M. The first three lectures will be on the Dental Problem in Relation to School Children, by Sir Harry Baldwin, on Feb. 10th; on the Prevention of Nervous Affections in the Young, by Dr. Risien Russell, on Feb. 17th; and on Diet in Schools, by Dr. L. R. Lempriere, on Feb. 24th. A number of seats will be kept for Fellows, Members, and Associates of the Institute, but there will be ample accommodation for others interested in health problems, and seats will be reserved for the whole course on application to the secretary.

WELSH HOSPITALS REUNION DINNER.—The first reunion dinner was held at Cardiff on Jan. 16th. Colonel A. W. Sheen, who commanded the Netley and Overseas Hospitals, presided, and was supported by Lieut.-Colonel H. G. Cook, who succeeded Colonel Sheen in the command of the Netley Hospital; by Sir W. J. Thomas, the greatest benefactor of the hospital; by Alderman J. Robinson, who as Lord Mayor of Cardiff supported the hospitals throughout, and by a representative company of over 100 of all ranks. Colonel Sheen said that the Welsh Hospital was the first voluntary hospital in the war, its inception dating from August 8th, 1914. After a reference to those who lost their lives on service, he spoke in detail of the work of the Overseas Hospital in India with its 3000 beds. It was felt that a dinner which had produced so many interesting meetings should be repeated.

BUREAU OF HYGIENE AND TROPICAL DISEASES.—By decision of the hon. managing committee of the Tropical Diseases Bureau, and with the approval of the Secretary of State for the Colonies, the Bureau's name has been changed to "Bureau of Hygiene and Tropical Diseases." The Bureau traces its history back to 1908, when, as a result of the International Sleeping Sickness Conference of 1907, the Colonial Office founded the Sleeping Sickness Bureau which, for four years, carried on its work of preparing and publishing the *Sleeping Sickness Bulletins* in a room put at its disposal by the Royal Society. Towards the end of this period it brought out also the *Kala-Azar Bulletin*, and in 1912 it outgrew its accommodation and moved to the Imperial Institute. Here its scope was widely increased and it became the Tropical Diseases Bureau, publishing in place of the journals named the *Tropical Diseases Bulletin*, now in its twenty-third volume, and the *Tropical Veterinary Bulletin*, of which 13 volumes have appeared. In 1920 it again outgrew its quarters and removed to what was then the new building of the Seamen's Hospital Society at 23, Endsleigh-gardens, where it occupies rooms put at its disposal by the new School of Hygiene and Tropical Medicine. Last year the managing committee, recognising the advances made in the practice of preventive medicine and the increasing need of the tropical and other Colonies for recent information on all branches of hygiene, decided to replace the Sanitation Supplements of the *Tropical Diseases Bulletin* by a monthly *Bulletin of Hygiene*, planned to meet the needs of the Dominions as well as the Colonies. The new journal will make its appearance this week. Dr. J. F. C. Haslam, recently Government medical officer of health of British Guiana, has replaced Colonel A. Alcock as assistant director and is in editorial charge of the new bulletin. The Bureau's name is now co-extensive with its activities.

THE LATE DR. THOMAS BERRY.—Whilst attending a dance arranged by the Woolwich Tuberculosis Care Committee on Jan. 22nd, Dr. Thomas Berry, who was a well-known practitioner in the Woolwich district, collapsed and died within a few minutes. Dr. Berry was a graduate of Glasgow University and was about 60 years of age.

MIDDLESEX HOSPITAL ON THE FILM.—A Pathé film of scenes in Middlesex Hospital has been prepared in support of the appeal for the rebuilding fund. The film shows the museum, work proceeding in the laboratories, the wards strutted to prevent collapse, the preparations for an operation, and so forth. Twelve minutes are required for its exhibition.

POOR-LAW HOSPITAL AT ROMFORD.—Last week Mr. Charles Rhys, M.P., opened two additional hospital blocks and a new nurses' home which the Romford Guardians have erected at a cost of nearly £100,000. There are 112 beds in each of the new blocks and accommodation has been provided for 100 nurses. The extension is necessitated by the development of the Becontree estate and other large adjacent areas.

"GOUT" AND ORTHOPÆDICS.—The Flintshire County Council is establishing a clinic for the treatment of orthopædic cases, the staff of which will be provided by Miss Hunt, the founder of the Shropshire Orthopædic Hospital. At a meeting explanatory of the scheme, Miss Hunt said that girls frequently complained to her of gout in the feet, whereas they were suffering from shoes with pointed toes and high heels.

LAW OF INQUESTS: CORONER URGES REFORM.—At an inquest on Jan. 21st, Mr. C. W. Surridge, the Manchester city coroner, drew attention to the unfortunate fact that inquests have to be held at the place where the body lies. In an accident case, such as the one he was dealing with, the proper place to hold the inquiry was the place where the accident occurred—where the coroner and jury were familiar with the locality. What prevented this common-sense procedure was the law enforcing the viewing of the body by the coroner. "I deeply regret," said Mr. Surridge, "that the draft of the new Coroners' Bill perpetuates this useless anachronism."

THE LATE DR. ROBERT BELL.—Dr. Bell, who died at his home in Kensington, on Jan. 20th, in his eighty-second year, had been physician to the Glasgow Hospital for Women for a period of 21 years, when, in 1896, he turned his attention to the problems of cancer. The direction which that attention took is well known. He came to London in 1901, became physician at the Battersea or Antivivisection Hospital, and published his view that cancer was a preventable disease due to contravention of the laws of nature, and that the disease was only made worse by operative interference. He wrote a book in which he submitted that complete disappearance of the disease occurred in the majority of cases of those who submitted themselves sufficiently early to his method of treatment, and he seems to have honestly believed that the rest of the medical profession would have adopted his views had they not been prevented by the loss of pecuniary returns.

MILK INEFFICIENTLY PASTEURISED.—A summons, stated to be the first of its kind in the country, was dismissed at the Wigan police court on Jan. 11th, for the alleged selling of pasteurised milk which had not undergone efficient pasteurisation. Evidence was given that a consignment of milk was received from the defendants at Wigan by a local retail firm, and that samples taken at the station had been submitted to Mr. Ernest Melling, analytical chemist to the corporation, who stated that although they were of very good quality the samples had not responded to the special colouration test to which he had submitted them, as efficiently pasteurised milk should have done. The milk had not been retained at a temperature of 150° F. for half an hour to complete pasteurisation which purchasers might expect. The manager of the Dalbeattie and District Farmers' Association, which supplied the milk to the defendants, admitted that since Nov. 2nd, at the request of customers, they had heated the milk to 150° F., but had not retained it at that heat for the usual half hour. It was not sold as pasteurised milk. Mr. Gilbert Hicks, Barnard Castle, who appeared for the defence, said that the case was extremely interesting and was novel for a police court. It was submitted that if there had been an offence—which was not admitted—the proceedings had been taken under the wrong Act—viz., the Food and Drugs Act instead of the Milk and Dairies Act of 1922. The magistrates after consultation dismissed the case.

GLASGOW ROYAL MATERNITY HOSPITAL.—Lady Blythswood last week opened new laboratories and administrative offices. The laboratories will provide facilities for research as well as for the ordinary work of the hospital.

HOSPITAL, HEALTH, AND NURSING EXHIBITION.—The sixteenth annual exhibition is to be held in the Central Hall, Westminster, from April 13th to 16th, and will contain a hospital section organised by the Hospital Officers, Association. Applications for space should be made immediately to the Secretary, 12B, Belsize Park-gardens, London, N.W. 3.

DONATIONS AND BEQUESTS.—Mr. Williamson Lamplough, underwriter, Blackheath and Bishopsgate, E.C., besides many other bequests, gave £1000 to the new medical fund of the Wesleyan Missionary Society.—Miss Agnes Marie Jacobina Zimmermann, of Devonshire-street, W., composer and musician, besides other bequests, left to the Hospital of St. John and St. Elizabeth, Grove-road, N.W., £1500 for an Agnes Zimmermann bed; £1200 to the New Hospital for Women, Euston-road, N.W., for an Agnes Zimmermann bed; £100 each to the Middlesex Hospital; the Royal Hospital for Incurables, Putney; the Metropolitan Convalescent Institution, the St. Marylebone Dispensary, the Seamen's Hospital, Greenwich; and £50 each to the Dental Hospital, Leicester-square, the Royal Hospital for Diseases of the Chest, City-road; and the Florence Nightingale Hospital.—Mr. George Frederick Spittle, Solihull, Birmingham, who left estate of the value of £32,433, after certain bequests, left his property to his wife, and on her death he made further bequests, and gave two beds in the Birmingham General Hospital to be endowed at the cost of his residuary estate, and to be named after his wife and himself; also £2000 to the Birmingham Bluecoat School, £1000 each to the Birmingham and Midland Eye Hospital and the Birmingham and Midland Hospital for Women; £500 each to the Birmingham and Midland Ear and Throat Hospital, the Royal Orthopædic and Spinal Hospital, Birmingham; the Royal Institution for the Blind, Birmingham; the Birmingham Children's Hospital; the Queen's Hospital, Birmingham; the Jaffray Branch Hospital, Birmingham, and the Birmingham Medical Mission, and the ultimate residue of his property for charitable purposes as his wife may appoint.—Miss Mary Elizabeth Norman, Rugby, left £1000 to the Hospital of St. Cross, Rugby, for the endowment of a bed.—Mr. Alfred Davies, Handsworth, Birmingham, left £500 each to the Birmingham and District Cripples Union and the Birmingham Royal Institution for the Blind.—Mr. William Heming Way, of Leeds, brewer, left £2000 to the Leeds General Infirmary, £1000 to the Leeds Public Dispensary, and £500 each to the Hospital for Women and Children, Leeds; the Leeds Maternity Hospital, and the Leeds Workpeople's Hospital Fund for the convalescent homes.—Mr. Henry Griffith Thomas, mining engineer, of Swansea, besides bequests to other institutions, left £1000 each to St. Dunstan's Hostel for Blinded Sailors and Soldiers and the Swansea General and Eye Hospital.—The Government of British Guiana has sent a second donation of £100 to the Ross Institute Hospital for Tropical Diseases, Putney Heath.—The late Sir Charles Brown by will left £50,716. The proceeds of his residence and effects will go to the Harris Orphanage. Preston Royal Infirmary's convalescent home, Lostock Hall, is to get two-thirds of the residue of his estate, about £30,000 or perhaps more, and Preston Borough Police Poor Children's Convalescent Home at Lytham, the income from the investment of the other third on the death of his sister. This will be about £15,000. He left £1000 to Cambridge University Research Hospital.—Mrs. Sarah Martha Grove-Grady left, among other large bequests, £4000 to the British Home and Hospital for Incurables, Crown-lane, Streatham, S.W.; £1000 to the Royal Blind Pension Society of the United Kingdom, of Southwark Bridge-road, S.E., for the benefit of female pensioners only; and £1000 to the Royal Society for the Indigent Blind, Leatherhead.—Mrs. Mary Margaret Fair Menzies or Maxwell, of Bangholm Bower, Trinity-road, Goldenacre, Edinburgh, left £1000 to the Edinburgh Cripple and Invalid Children's Aid Society and £500 to the Edinburgh District Branch of the Scottish National Society for the Prevention of Cruelty to Children, among other bequests.—Miss Elizabeth Nicholson, of Leonard-street, Keswick, Cumberland, left £2100 to the Westmorland County Hospital for three cots.—Colonel Gilbert Omerod Spence, Kirklevington, Yarm-upon-Tees, Yorks, besides other bequests, left £1000 each to the Stockton and Thornaby Hospital and the District Nursing Association.—The Royal Manchester Children's Hospital has received £1000 from the executors of Mr. John Chadwick Barlow to endow a bed.—A private donor has offered to give £5000 if the remaining £15,000 of the bank overdraft of the West London Hospital can be quickly subscribed.

RETIREMENT OF DR. G. S. MIDDLETON.—On Jan. 14th, to mark his retirement from active consultant practice, some 120 medical men from different parts of the British Isles entertained Dr. G. S. Middleton to dinner at the Central Station, Glasgow. Dr. William Sewell presided; Dr. William G. Dunn, Dr. J. B. Mackenzie Anderson, and Dr. George MacFeat acted as croupiers, and Dr. John Fergus as secretary. Dr. Sewell, who proposed the health of Dr. Middleton in a speech reminiscent of old college and hospital days, referred to the personal qualities of Dr. Middleton, to his loyalty of heart, his integrity of purpose, his fine judgment and ripe experience, and his unswerving devotion to the highest traditions of his profession. He had been a valuable assistant to the late Sir William Gairdner, and his connexion with the Royal Infirmary and the Royal Hospital for Sick Children, to which institutions he was now consulting physician, and with the Western Infirmary, had made for him many friends, several of whom were present that evening. At the end of his speech Dr. Sewell presented Dr. Middleton with a handsome solid silver salver and coffee service. Sir Hector Cameron supported the toast, to which Dr. Middleton replied. The toast of the Glasgow Medical School was proposed by Dr. C. O. Hawthorne and replied to by Dr. W. R. Jack.

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Feb. 1st.—8.30 P.M., Social Evening. 9.30 P.M., Dr. F. J. Poynton: The Part Taken by Doctors in the Early Days of Aeronautics.
TUESDAY.—5.30 P.M., ORTHOPÆDICS. (Cases at 5 P.M. by Mr. W. Rowley Bristow, Mr. P. Bernard Roth, Mr. Rocyn Jones, and others. 8.30 P.M., PATHOLOGY. Laboratory Meeting at University College Hospital, W.C.
WEDNESDAY.—4 P.M., SURGERY. Clinical Meeting at St. Bartholomew's Hospital, E.C. Operations at 4.15 P.M., and demonstrations in other departments.
THURSDAY.—8 P.M., OBSTETRICS AND GYNÆCOLOGY. Specimens by Dr. McCullagh and Dr. Everard Williams. Short communications by Dr. Abercrombie and Mr. Herbert Paterson. Demonstration by Dr. Barnard. Prof. Louise McIlroy: Pulmonary Tuberculosis Complicated by Pregnancy.
FRIDAY.—5 P.M., LARYNGOLOGY. Cases and specimens will be shown at 4 P.M. 8.30 P.M., ANÆSTHETICS. Dr. C. F. Hadfield: Nitrous Oxide: Its Impurities, and the Establishment of Tests Suitable for Official Adoption.
SATURDAY.—10.30 A.M., OTOLOGY. Cases by Dr. Dan McKenzie, Mr. F. W. Watkyn Thomas, Mr. Archer Ryland, and others at 9.45 A.M.

ROYAL INSTITUTION, 21, Albemarle-street, London, W.
TUESDAY, Feb. 2nd.—5.15 P.M., Mr. Eric Rideal, D.Sc.: Surface Action.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Feb. 1st.—5 P.M., Prof. Arthur Edmunds: Pseudo-Hermaphroditism and Hypospadias and their Surgical Treatment.
WEDNESDAY.—5 P.M., Prof. J. E. Adams: The Surgery of the Jejunum.
FRIDAY.—5 P.M., Prof. Musgrave Woodman: Malignant Disease of the Œsophagus.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.
MONDAY, Feb. 1st, to SATURDAY, Feb. 6th.—Fellowship of Medicine lecture, Medical Society, 11, Chandos-street. Thurs., 5 P.M., Dr. McNee: The Treatment of Renal Disease (free to members of the medical profession).—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E. Instruction in the O.P. Department from 2.30 P.M. Tues. and Fri., 5.30 P.M., Venereal Clinic.—LONDON LOCK HOSPITAL, Dean-street, W. Comprehensive course. Instruction in the O.P. Department daily and lectures dealing with the various aspects of V.D.—LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. Thurs., 2 P.M., Mr. H. J. Paterson: Special clinical demonstration for members of the Fellowship of Medicine. Further information from the Secretary of the Fellowship of Medicine.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Feb. 5th.—3 P.M., Mr. Watkyn-Thomas: Swellings of the Upper Jaw.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.
WEDNESDAY, Feb. 3rd.—Dr. Harrison: Blood-Sugar Curves and their Interpretation.
THURSDAY.—4 P.M., Mr. Doyne: Ocular Torticollis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE will be held from FEBRUARY-MARCH, 1926.

*CLINICAL LECTURES AND DEMONSTRATIONS.*

MONDAY, Feb. 1st.—12 noon, Pathology of the Nerve Cell: Dr. Greenfield. 2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Hemiplegia: Dr. Risien Russell.

TUESDAY, Feb. 2nd.—2 P.M., *Out-patient Clinic*: Dr. Walshe. 3.30 P.M., Disseminated Sclerosis: Dr. Grainger Stewart.

WEDNESDAY, Feb. 3rd.—2 P.M., Clinical Demonstration: Dr. Gordon Holmes.

THURSDAY, Feb. 4th—12 noon, Anatomy and Physiology of the Nervous System. Dr. Walshe. 2 P.M., Out-patient Clinic Dr. Kinnier Wilson. 3 30 P.M., The Paralysed Bladder. Dr. Gordon Holmes.

FRIDAY, Feb. 5th—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., Demonstration of Re-educative Exercises: Mr. Elmquist

Additional particulars will be given in further announcements.

J. G. GREENFIELD, Dean of Medical School.

NORTH EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Feb. 1st.—10 A.M., Surgical Out-patients: Mr. W. E. Tanner. 10.30 A.M., Gynæcological Operations: Mr. A. E. Giles; Throat, Nose and Ear Operations: Mr. W. Ibbotson. 2 P.M., Medical, Surgical, and Gynæcological Clinics, Operations. 6.30 P.M., Venereal Department.

TUESDAY.—2 P.M., Medical, Surgical, Throat, Nose and Ear Clinics, Operations. 4.30 P.M., Mr. T. H. C. Benians. Specimens illustrating Diseases of the Breast.

WEDNESDAY.—10.30 A.M., Surgical Operations: Mr. E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 6.30 P.M., Venereal Department.

THURSDAY.—10.30 A.M., Dental Out-patients: Mr. E. S. Pierrepont. 2 P.M., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

FRIDAY.—10.30 A.M., Eye Operations: Mr. N. Fleming. 2 P.M., Surgical, Medical, and Children Clinics, Operations. 3 P.M., Gynæcological Clinic. 6.30 P.M., Venereal Department.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

THURSDAY, Feb. 4th.—5 P.M., Mr. L. C. Rivett: Infant Feeding.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THURSDAY, Feb. 4th.—4 15 P.M., Dr. Charles Singer: The History of Malaria (first of four lantern lectures, open to medical students of the University of London).

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester square, W.C.

TUESDAY, Feb. 2nd—5 P.M., Dr. H. MacCormac: Lupus Erythematosus.

THURSDAY.—5 P.M., Dr. A. M. H. Gray: Xanthoma. Herpes.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.

WEDNESDAY, Feb. 3rd.—5.30 P.M., Mr. F. Coleman: The Value of "Set" Operations on the Jaws and Teeth.

ROYAL SANITARY INSTITUTE.

FRIDAY, Feb. 5th in the Town Hall, Bradford).—3 P.M., Discussion on Child Welfare Centres and their Adjuncts. 5 P.M., Discussion on Town Planning and Improvement Areas.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.

FRIDAY, Feb. 5th.—3.30 P.M. (at the Royal Hospital). Mr F. Wilson Demonstration of Surgical Cases.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE.

FRIDAY, Feb. 5th.—4.30 P.M. (at Whitworth street West Branch), Dr. F. H. Lacey: Common Ailments of Pregnancy.

## Appointments.

WHITMAN, H. D. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Roath medical district and the Roath and Cathays Children's Homes, S. Wales.

## Vacancies.

*For further information refer to the advertisement columns.*

*All Saints' Hospital, 49/57, Vauxhall Bridge-road, S.W.*—Non-Res. Jun. H.S. £100.

*Barnsley County Borough.*—Asst. M.O.H., &c. £600.

*Barrow-in-Furness, North Lonsdale Hospital.*—H.S. £175.

*Bolingbroke Hospital, Wandsworth Common, S.W.*—Res. M.O. £200. Also H S. At rate of £120.

*Bootle Borough Hospital.*—Jun. H.S. £125.

*Bristol Eye Hospital.*—H.S. £150.

*Dorset Mental Hospital, Herrison, near Dorchester.*—Deputy Med. Supt. and Pathologist. £575.

*East London Hospital for Children and Disp. for Women, Shadwell, E.*—S. for Nose, Throat, and Ear.

*Exeter, Royal Devon and Exeter Hospital.*—Sen. H.S. £200.

*Hertford County Hospital.*—H.S. At rate of £150.

*Hospital for Sick Children, Great Ormond-street, W.C.*—Res. Med. Supt. £300.

*Isle of Wight County Council.*—Two Asst County M.O.'s. £730 and £750 respectively.

*Leeds City.*—Chief Clin. Tuberculosis O. £1000.

*Leeds Public Dispensary.*—Sen. Res. M.O. £200.

*Liverpool Children's Hospital, Heswall Branch.*—Res. M O At rate of £150.

*Liverpool Children's Hospital, Myrtle street.*—Two Res. H.P.'s and Two Res. H S.'s. All at rate of £60.

*Liverpool Open-Air Hospital for Children, Leasowe, Cheshire.*—Res. Jun. M.O. £200.

*Liverpool Royal Infirmary.*—Hon. S. to Lock Dept.

*London Lock Hospital, 91, Dean-street, W.*—Surg. Reg. £100.

*Manchester, Ancoats Hospital.*—H.S. At rate of £100.

*Manchester Ear Hospital.*—Hon. Radiologist.

*Manchester, Ministry of Pensions Hospital, Grangethorpe.*—Jun. M.O. £350.

*Mildmay Mission Hospital, Austin street, Bethnal Green, E.*—Hon. Emergency S.

*Northampton County Mental Hospital, Berry Wood.*—Sen. Asst. M.O. £500.

*Northampton General Hospital.*—Third H.S. At rate of £150.

*Northamptonshire County Council.*—Tuberculosis Officer. £750.

*Northern Hospital, Winchmore Hill, N.*—Asst. M.O. for Encephalitis Lethargica Unit. £550.

*Nottingham General Dispensary, Broad street.*—Res. Surg. £250

*Nottingham General Hospital.*—H.S. for Ear, Nose and Throat Dept. At rate of £150.

*Queen's Hospital for Children, Hackney-road, Bethnal Green, E.*—Cas. O. At rate of £100.

*Royal Northern Hospital, Holloway, N.*—Cas. O. At rate of £90. Also Asst. Surg. O. £75.

*Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.*—Part-time Pathologist. £200.

*St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.*—H.S. At rate of £75.

*Salford Union Infirmary, Hope, Pendleton, near Manchester*—Two Asst. Res. M.O.'s. £300 and £275 respectively.

*Sheffield City.*—Jun. Asst. Tub. O. £350.

*Sheffield Royal Hospital.*—Ophth. H.S. £80.

*Southampton, County Borough Isolation Hospital.*—Res. M.O. £360.

*Swindon Borough.*—Asst. to M.O.H. £600.

*Warrington, Lancashire County Mental Hospital, Winwick*—Deputy Med. Supt.

*West Bromwich and District Hospital.*—Res. H.S. £220.

*West London Hospital, Hammersmith, W.*—Asst. Path. £250

*Wilts County Council, Venereal Diseases Clinic, Swindon.*—Part-time M.O.'s. £1 11s. 6d. per session.

THE Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments for Certifying Factory Surgeons at St David's, Pembrokeshire; and at Plymouth, West, Devonshire.

## Births, Marriages, and Deaths.

### BIRTHS.

GIBB.—On Jan. 19th, in London, the wife of James Gibb, M.A., M.B., Ch.B., Downham Market, Norfolk, of a daughter.

HINE.—On Jan. 18th, at The Ivies, Carter Gate, Newark-on-Trent, the wife of Dr. Hine, of a son.

PEGGE.—On Jan. 18th, at Elmfield-avenue, Leicester, the wife of Dr. A. Vernon Pegge, of a son.

SHIRES.—On Jan. 25th, at Welbeck street, W., the wife of Dr. Bertram Shires, of a son.

### MARRIAGES.

GREEN—ROBERTSON.—On Jan. 22nd, at All Saints' Church, Willian, Dr. Frederick Norman Green, to Margaret Campbell, third daughter of Mr. and Mrs. J. Campbell Robertson, of Nutleigh Grove, Hitchin, Herts.

### DEATHS.

BELL.—On Jan. 20th, at Thorney Court, Hyde Park gate, Dr. Robert Bell, aged 81.

DURDIN.—On Jan. 16th, at King's Lynn, Robert Charles Garde Durdin, M.D., L.R.C.P.I., L.R.C.S.I.

FOX.—On Jan. 21st, at the Royal Free Hospital, of septicæmia, Iris Fox, M.D. Lond.

MAWHOOD.—On Jan. 20th, at Green Meadows, Ascot, Reginald Hawksworth Mawhood, M.B., B.C. Cantab., F.R.C.S. Eng., aged 41 years.

PANTIN.—On Jan. 21st, at a nursing home, Boscombe, Dr. Mabel Pantin.

ROBINSON.—On Jan. 16th, at Harpur street, Bedford, George Robinson, M.R.C.S., L.M., J.P., aged 87 years.

SCORESBY-JACKSON.—On the 20th Jan., at a nursing home in London, Arabella Mary, younger daughter of the late Robert Edmund Scoresby-Jackson, M.D., F.R.S.E., &c., and sister of Dr. Margaret Scoresby-Jackson, 28, Weymouth-street, W.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## THE TREATMENT OF CONTAMINATED WOUNDS WITH BIPP AND A MODIFICATION.

By *Elizabeth L. Thal, M.D.*,

ASSISTANT AT THE HOSPITAL SURGICAL CLINIC OF THE SECOND MOSCOW STATE UNIVERSITY. (DIRECTOR: PROF. P. D. SOLOVIOFF.)

In 1916 Prof. Rutherford Morison suggested the treatment of contaminated wounds with a paste made up of bismuth, iodoform, and paraffin, and called bipp. He proposed that *septic wound cavities should be bathed with methylated* spirit and plugged with bipp, and closed by primary suture. Subsequently Morison himself only plugged small cavities and in larger ones spread the paste along the walls, whilst various modifications are in use by other surgeons, many of whom ignore the fundamental idea of the treatment—namely, cleansing and direct suture. In Germany and America the method is not much in use, and in Russia it has not been tried until recently.

### *A Modified Method.*

In the surgical clinic of the Second Moscow State University we applied Morison's method for about a year, *at first carrying out the instructions exactly and later* modifying and simplifying its details. We now use the following technique, which is simple to carry out and permits the sewing up of almost any contaminated wound:

1. The operative field is prepared by coating it with tincture of iodine.

2. The cavity is opened wide and pus and sequestra are *removed. There is no necessity, however, for any deep or* rough excision of the walls or the removal of the pyogenic membrane.

3. After careful examination of the cavity it is cleansed with pure alcohol. Excess of alcohol is removed and bleeding vessels are ligatured.

4. The walls of the cavity are mopped with a liquid of the following *composition: 8 parts of iodoform dissolved* in 25 parts of ether and 75 parts of alcohol. The ether instantaneously evaporates, the alcohol passes off, and the cavity is left uniformly coated with a thin covering of exceedingly minute crystals of iodoform which have been just precipitated. We do not traumatise the cavity *of the* abscess by rubbing in the paste, and the tissues are not eroded by a more or less massive layer *of foreign* substance. Such a mass has either to be dissolved and absorbed, or—*which is more unpleasant*—must fall out piecemeal, and it can only gradually be replaced by cicatricial tissue; the cicatrix under these circumstances is, of course, massive and indurated. When only solutions are used *the tissues* may be brought into contact by means of a sunk suture or, if preferred, by the aid *of a properly* applied compressing bandage or a plaster dressing.

5. The final act is complete suture of the skin. For the sunk stitches we use catgut, for the skin stitches silk; both these substances are previously coated with *the original* Morison bipp paste of the following composition: 8 parts of subnitrate of bismuth, 16 parts of iodoform, 8 parts of liquid paraffin.

### *Reduction of Tension.*

The whole of this process is exceedingly simple; it is reduced to the bathing of the cavity with two liquids, and occupies not more than three to five minutes. There are, however, two facts to be taken into account. *First, that* during the time of the *operation there* is a succession of a dirty and a clean moment, and it is *necessary* to cleanse oneself, the instruments, and the field of operation, as is done in any intestinal *operation. Omission of* this precaution is a cause of failure. Secondly, careful apposition of the edges *of the* skin wound must be effected without stretching them in any way For this *purpose* slight incisions into the skin in order to relax it may be made at the sides of the operative suture. It should be made a rule that *the loosening* cuts into the skin are made in all those cases where the skin at the moment of operation is *found to be* involved in the area of infiltration, because stitches in highly infiltrated skin must, of *necessity, break through* quite soon after the operation, before the infiltration has had time to complete its *retrogression*. In addition to reducing strain in the region of the suture, parallel cuts in *the skin at once remove* the high tension existing in the area of the infiltrate and ward off the formation of œdema in the *region* of operation; so that this insignificant interference should never be omitted wherever the least indication for it *exists*.

Usually after the closure of a large cavity, as above described, there is *at first a more or less* copious sero-sanguineous secretion which oozes between the stitches but does not impair the general course of healing. It does not influence the temperature curve, and only necessitates changing the gauze which covers the line of the suture, once every three or four days. *If, however, there is but little* secretion or none at all, re-dressing must be done as rarely as possible.

### *Pharmacological Considerations.*

I shall not dwell on the chemical and pharmacological properties of iodoform and alcohol and will merely point out that we were entitled to exclude bismuth not only on account of its unpleasant mechanical influence, but also because it does not *produce any considerable healing effect*. A detailed examination of bipp, carried out by Chambers and Goldsmith,[1] has shown that its bactericidal power by no means depends on the nitrate of bismuth contained in it. The latter, or rather the inconsiderable quantity of free nitric acid given off from it, is probably only a *catalyst which* accelerates the liberation of free iodine from iodoform under the influence *of oxygen*.

The modified method which we use does *not produce* iodism, nor is there any poisoning from the inconsiderable quantity of pure alcohol introduced into the body. The only question of essential importance is *whether we do not* create considerable local injury—*whether we do not* impair vital activity and hinder the progress of healing. Only if *we are able to answer this question in the negative* are we entitled to adopt so radical an antisepsis of the wound. Neither we nor other writers (few it is true) who have dealt with the bipp method have *observed* any mishap. *I will* quote two examples in which unhealthy tissues of low healing power were involved:—

(*a*) An ulcerating *cancer* of the skin on the site of previous lupus; extirpation. Extensive flap formation, the flaps being cut out of the cicatricially modified lupus skin. Careful twice-repeated "bipping" of the base and the flaps. Smooth union. A year later the patient attended again *with secondary* deposits of cancer, but the flaps were in an excellent condition.

(*b*) A purulent and diffuse tuberculous lympho-granuloma *on the neck* was opened; the cavity was treated with our modification of the bipp method and closed with sutures. It was difficult to replace in the cavity of the abscess the abundance of fungous *masses* which *had developed*. The silk stitches were passed through highly sclerosed œdematous tissue. On the ninth *day* they were removed and the wound had healed up by first intention. Two and a half weeks after the operation the patient attended and the sutured line was found in good condition. We do not know how the patient fared after this and what was the further course of his fundamental disease, but the direct *power* of healing and cicatrisation of the tissues had not suffered to any noteworthy extent.

Judging therefore by practical results, antisepsis with immediate closure of infected wounds is thoroughly justified, and we believe that theoretical considerations *afford similar* justification.

Inflammation in the tissues is *manifested* by two fundamental processes—viz., excessive osmotic *pressure*, and excessive hydrogen-ion concentration at the site of injury, which may be 50 times increased. By incision the pressure is *relieved*, and just as we do not wait to *allow an abscess* to rupture spontaneously, so we need not refuse *to alter* the chemical and physico-chemical reactions of the inflamed tissues so far as we are able. Only *on the basis of* some alteration of reaction can we explain the fact observed by Morison and others, that for a *long time* after operation cultures from the sero-sanguineous discharge from *the* wound which oozes out between the stitches will still produce a scanty growth of organisms, although all signs of inflammation disappeared from the first day.

### *Results of Trial.*

Our clinic is exceedingly poor in pyogenic material, *and the treatment above described* was applied to only 40 cases during a year. All of them were infections *by Staphylococcus aureus*. No definite deductions, therefore, can be made, but the *impression* we have received *is unquestionably* favourable. We applied the method in abscesses of the soft tissues and in varied plastic *operations* on the skin, and the flaps in these cases always united well and we did not have to concern ourselves beforehand with the asepsis of the region of transfer. Our rule was to apply it in *osteomyelitis and chondritis and* in suitable cases of tuberculosis of the bones and joints, complicated by mixed *infection*. After the operation for osteomyelitis we never observed the *sequestration of the bones which* was previously so frequent.

The regional lymphatic glands never gave any observable reaction *in our cases*, the stitches could be *removed* on the ninth to fourteenth day. The reduced local and general reaction and the comparatively early function of the operative region make clearly evident the advantages of this method, whilst even in the case of failure all that is necessary is to loosen the stitches and the patient is in the same position as a subject treated without plugging, except that his infection is more or less reduced.

## COLONIAL HEALTH REPORTS.

### *Gold Coast.*

A report by Mr. A. A. C. Finlay, acting Colonial Secretary, for the year ending March 31st, 1924, states that the population of the Gold Coast and its dependencies at the last census was 2,299,961. The number of Europeans resident in the Colony in 1924 was 3043, of whom 994 were officials, 97 missionaries, 1425 engaged in mercantile occupations, and 527 in mining. 2911 births and 117 still-births were registered during the year, and 3285 deaths, these figures including Europeans. The number of births stated is lower than it should be, as birth registration is still unpopular amongst the illiterate classes. The figure for deaths is approximately accurate, for no burial permits are granted without registration, the issuing of permits and registration of deaths being done by the same officer. The chief causes of death were pulmonary and intestinal diseases. The death-rate per 1000 among the European population was 7·88 and the invaliding rate 28·59. The ten deaths amongst European officials were due: two to yellow fever, two to blackwater fever, three to heart failure, and one each to chronic myocarditis, rupture of thoracic aneurysm, and cerebral embolism. Of the 14 deaths amongst European non-officials, eight were due to yellow fever, two to blackwater fever, and one each to alcoholism, fracture of skull, cerebral malaria, and cyanide poisoning. The average daily number of European officials on the sick list compared to the average daily number resident in the Colony was 2·42 per cent. Treatment was given in 5963 cases of malaria, 551 of dysentery, 534 of pneumonia, 111 of tuberculosis, 14 of plague, two of small-pox, and six of sleeping sickness. The sanitary condition of most of the large towns was fairly satisfactory. 190,513 houses were inspected during the year and the average larval index was 0·94 per cent. There were 3726 prosecutions under the Destruction of Mosquitoes Order. There was an outbreak of relapsing fever of a very mild type and low mortality-rate. Plague broke out in Sekondi, and up to the end of the year the case-mortality of the known and suspected cases worked out at 60 per cent. There has been no outbreak of small-pox, though nine cases were reported, eight in the Northern Territories and one in the Colony. The number of vaccinations performed was 82,425, and 36,468, or 44·24 per cent., were reported as successful. The efforts of the medical and sanitary authorities in promoting the treatment of disease and the knowledge of general hygiene continue to exercise a beneficial effect on the general health of Europeans. The climate, though hot and damp, is cooler than that of most tropical countries situated in the same latitude. It is not in itself unhealthy; but an evil reputation has been earned for it in the past by the prevalence of mosquito-borne diseases against which all possible precautions have constantly to be taken. The Gold Coast is peculiarly free from many of the discomforts associated with tropical countries; hot nights and intense heat by day are the exception rather than the rule, while insects are comparatively unobtrusive. The rainfall in 1923 varied as follows at the different stations: Accra, 21·16 inches; Aburi, 43·14; Sekondi, 39·29; Axim, 109·18; Tarkwa, 71·72; Kumasi, 55·75; Tamale, 36·03. At Accra the mean shade temperature was 81° F., at Kumasi 79·4°, and at Sekondi 79·8°. The mean daily range of temperature in Accra was 15·6°.

### *Gibraltar.*

Mr. C. W. J. Orr, Colonial Secretary, in the annual report, states that the estimated total civil population at the close of 1924 was 17,324, of whom 16,177 were fixed residents. These figures represent the population between sunset and sunrise; to calculate the daily population it would be necessary to add some 8000 aliens and 1500 British subjects resident in the neighbouring Spanish town of La Linea, who come into Gibraltar daily. The number of births during the year 1924 was 360, being at the rate of 22·25 per 1000, among the fixed population only; under the Aliens Order in Council no alien may give birth in the colony; 254 deaths were registered, and the crude death-rate was 14·66 per 1000. Infantile mortality was 91·6 per 1000, and deaths from pulmonary tuberculosis 1·5 per 1000. The number of deaths from cancer was 27, an increase of nine over the previous year. The general health during the year was very satisfactory. There was no disease in epidemic form. The climate of Gibraltar is in general mild and temperate, though somewhat hot and oppressive during the months of July and August. The meteorological record for 1924 showed 70·88° F. as the mean maximum temperature, the highest shade temperature being 91° on July 17th and August 19th, and the lowest, 38°, on Feb. 28th. The rainy season spreads over the period from September to May; the annual average rainfall is 35 inches, but in 1924 44 inches were registered, of which 15·17 inches fell in February.

## Public Health in West Indian Islands.

### *Cayman Islands.*

These three small islands in the Caribbean Sea are situate north-west of Jamaica (of which colony they are a dependency), and approximately midway between that island and the south-west of Cuba. Mr. H. H. Hutchings, the Commissioner, in his report for 1924, gives the estimated population as 5365. There were 139 births (26 per 1000) and only 55 deaths (10 per 1000). The general health is good. The staple food of the people consists of cassava, yams, sweet potatoes, and bread fruit, all locally grown, and the ordinary wheat and corn products by way of imports. These constitute an almost entirely starchy diet which induces mild digestive disorders. There were no epidemics in 1924. Of the 55 deaths, 16 were returned as infants, two under 20 years, and 31 between 50 and 103, 27 being persons over 70 years of age. There were three deaths from pulmonary tuberculosis and two from cancer, all persons in early life.

### *Grenada.*

The estimated population at the end of 1924 was 68,057, its density being 518·17 per square mile. The birth-rate for the year was 31·86, and the death-rate 16·8 per 1000, the latter comparing very favourably with that in other West Indian Colonies. The death-rate per 100 births of infants dying under 1 year was 11·10. Through the efforts of Lady James, an infant welfare centre was established towards the end of the year, and a creche has now been opened. The principal causes of death during the year were: diarrhœa and enteritis, 296; malaria, 108; enteric fever, 22; dysentery, 34; pulmonary tuberculosis, 52; and syphilis, 16. Grenada, in the extreme south of the Caribbean Sea, is the nearest British island to the mainland of South America, with the exception of Trinidad and Tobago. Its area is about 120 miles, but including Carriacou, an island to the north, 133 square miles. The country is mountainous and well watered by streams. St. George's Harbour, landlocked and deep-watered, is one of the most beautiful in the West Indies. The mountain spurs, clothed with forests to their summits, intersect the island into numerous picturesque valleys. There are two small lakes, formed in extinct craters, one called the Grand Etang, being situated near the centre of the island, 1740 feet above sea-level, while the other, Lake Antoine, is near the sea on the eastern coast. A sanatorium is established near the former. The climate can be classed as excellent, and from December to May is delightful. The trade winds are steadily prevalent during this period, but occasionally fail in the autumn months which are somewhat damp and hot. The range of temperature is small and tends to make the climate equable and healthy. The thermometer seldom reaches 90° F. in the shade or drops below 70°, and these occasions occur so rarely that they are specially recorded. The rainfall in the lowlands of the south is as low as 30 inches; in the mountainous centre it approaches 110 inches. At St. George's, midway between the two, the rainfall in 1924 was 81·51 inches, as compared with an average over 30 years of 74·83 inches.

### *St. Vincent.*

The general health of the island throughout the year 1924 was (states Mr. R. Walter, the administrator, in his annual report) good. The total population at Dec. 31st was 47,591. The birth-rate for the year was 37·72 per 1000, and the death-rate 16·49. The latter showed a considerable decrease as compared with 1923 when it was 22·1. Thirty cases of enteric occurred with ten deaths. Infantile mortality showed a considerable decrease, deaths of children under 1 year (excluding still-births) numbering 169 as against 237 in 1923, and the mortality-rate per 1000 births 99 as against 128. It is noteworthy that illegitimate births amounted to over 75 per cent. of all the births, and that out of 93 still-births 79 were illegitimate. The campaign against yaws was continued with success, a total of 3377 cases being treated, of which 1813 were cured. A residence was built for the district medical officer residing at Chateaubelair—a long-felt need—and various sanitary improvements were effected in the smaller towns, but the colony is still in need of a qualified chief sanitary officer to train and supervise the work of the sanitary inspectors. St. Vincent is one of the healthiest of all the West Indian islands. The climate may be divided into two seasons, wet and dry—the dry season from January to May, and the wet season from June to December. The coolest months are December to

April. The temperature throughout 1924 varied from 78·1 to 81·8° F. The mean monthly temperature was 80·2°. The rainfall at the Agricultural Experimental Station in Kingstown, 80 feet above sea-level, was 85·07 inches. Rain fell on 277 days, and the greatest fall for one day was 3·03 inches on July 29th.

## FINANCE OF VOLUNTARY HOSPITALS.

Mr. L. G. Brock, Principal Assistant Secretary of the Ministry of Health, addressing the Manchester Statistical Society on Voluntary Hospital Statistics, said that in Manchester the hospital statistics were more complete than in any other city outside of London. The report of the local voluntary hospitals committee was a model of its kind. Hospital statistics must supply answers to three vitally important questions: (1) Is the public doing its duty to the hospitals? (2) Are the hospitals solvent, judged by ordinary business standards? (3) If they are not solvent, in what directions can expenditure be reduced or income increased?

In 1924 more than 200,000 patients were treated at Manchester hospitals, but in spite of this at the end of the year upwards of 3100 persons were awaiting admission as in-patients. In general, the answer to the first question was satisfactory. The public was doing its duty to the hospitals. As regards income and expenditure, taking the voluntary hospitals of England and Wales, in 1922 there was a deficit of £203,000; in 1923 a surplus of £497,000; and in 1924 a surplus of £177,000. Industrial depression did not provide a sufficient explanation of recurring deficits. Sheffield, which had suffered from trade depression acutely, had steadily increased the income of its hospitals. Manchester was one of the black spots. The deficits on the ordinary income of the three years, 1922–23–24, were respectively £19,121, £30,378, and £18,072. In the Manchester hospitals in 1924 the percentage of the total ordinary income derived from endowments was 21·8; from patients' payments and public authorities, 32·3; and from voluntary gifts, 46·1. In Manchester the cost per bed in the various hospitals compared very favourably with the costs of similar hospitals elsewhere. It was doubtful if special whirlwind campaigns to reduce debts were really a sound method of raising revenue. They were almost always followed by a period of reaction. A steady increase of income was much more valuable than an occasional boom year. The total subscriptions to the Manchester hospitals in 1922 amounted to £55,169, and in 1924 to £81,026. If the hospitals were to retain the support of the middle classes, they must do something for them.

There was much to be said for paying wards, not as a means of raising revenue but as a means of maintaining interest in the voluntary system. If any unified appeal for new subscriptions was to be made in Manchester, it would be powerfully reinforced if some part of the proceeds could be marked for the provision of accommodation for middle-class patients, either on the lines of the Forbes Fraser scheme at Bath, or on the lines of St. Chad's Hospital at Birmingham. A most important possible source of increased revenue was workmen's contributions. The most hopeful method of developing this source of income was to establish some kind of mass contribution scheme. In urban areas probably the best known was the Sheffield scheme. At Sheffield, said Mr. Brock, the workers undertake to contribute a penny per pound a week of their wages, and the employers add 25 per cent. of the employees' contributions. In 1921 the contributions from workmen was £7,810, and from employers £2,500, and the estimated corresponding amounts in 1925 were £101,000 and £28,000. It is said that in the majority of cases the cost of collection did not exceed 3 per cent. of the gross amount collected.

## THE CLIMATES OF THE UNITED STATES.

CLIMATE may influence health in two ways: first, it may affect more or less directly the life, development, and virulence of the micro-organisms which are the specific cause of disease; and secondly, it may strengthen or weaken the individual's power of resistance against the attacks of these organisms. It must be remembered that a change of climate usually involves a change of residence, habits, occupation, and food; these are often of as great significance as the change of climate itself. Indeed, this has been recognised since the time of Hippocrates who wrote, "In chronic diseases it is advisable to go to another country."

Not since 1857, when Lorin Blodget's "Climatology of the United States" was published, has any attempt been made to give a concise and systematic account of the climates of the United States. Prof. Ward, of Harvard University, who has studied the subject for 25 years, has now given us a handy and readable volume,[1] well illustrated with graphs and maps, suitable for the purposes of teachers and students of climatology. The book also supplies such information as may be required by medical men, foresters, agriculturists, and the general public. The chapter headed Climate and Health gives a brief and unbiased synopsis of the general medical aspect of the climates of the United States. The States are fortunate in having a fair variety of climates, so that during the cold winters of the northern States one may travel south—for instance, in the eastern province to Florida. Again, during the heat of summer, one may travel to a cooler resort in the north. The western mountain and plateau region is of special interest in that it embraces the districts of Colorado which have become famous for the altitude treatment of pulmonary tuberculosis. The Pacific slope, with its great latitudinal extensions, includes a great variety of climates. It is, however, the southern coast of California which is its best known health resort, winter and spring being the favourite seasons.

The author deals only briefly with local differences between health resorts. The main part of the book deals chiefly with ordinary questions of meteorology such as temperature, frost, winds, rainfall, snowfall, humidity, sunshine, clouds, fog, thunderstorms, tornadoes, blizzards, and heat waves. There are also special chapters on Climate and Crops and the Climates of Alaska. Amongst the phenomena of more general interest discussed are heat waves, tornadoes, the Indian summer, and the Chinook wind. Spells of excessively hot weather, occurring at irregular intervals and lasting for various periods of time, are characteristic of the summers of the central and eastern United States, especially of the great Mississippi lowland, of the Ohio valley regions, and eastward to the immediate Atlantic coast. In connexion with these heat waves heat prostration and sunstroke are common. The numbers of deaths, especially those of infants and young children from cholera infantum, may become appallingly large. Dr. W. F. R. Phillips found that during the three weeks ending August 22nd, 1896, there were 2038 known deaths directly due to sunstroke, and the list was doubtless far from complete. Probably more than 12,000 cases of varying degrees of severity actually occurred.

The tornado is stated to be the most violent atmospheric phenomenon with which man has to contend. Its wind velocities are greater than those of the dreaded tropical cyclone. Its strength is superior to that of any structure which may be built to withstand it. In its fullest development it is peculiarly and characteristically American. It finds its real home in the great central lowlands of the eastern portion of the United States. Nowhere else in the world do tornadoes find equal opportunities for development. They resemble the great summer thunderstorms of the eastern United States in being typically American. They cause great damage and loss of life. The Indian summer is a more pleasing phenomenon. It comes in October or early in November after the equinoctial storms. It is usually described in poetic terms; the calm sunny days; the dry, mild, and genial atmosphere; the smoky haze which lends to the distant view a soft, indistinct, impressionistic tone and paints the sunset a glorious but subdued red; the wonderful colouring of the autumnal foliage; the welcome return, for a short space, of summer warmth following the first frosty nights and cool days of advancing winter. The Chinook wind is a characteristic feature of the eastern slope of the Rocky Mountains in Montana and Wyoming and as far south as Colorado. It is also noted elsewhere. It is a warm and dry wind, similar in all respects to the Swiss "foehn." It begins at any hour, day or night. In velocity it varies from a gentle breeze to a gale. It may blow steadily for hours or for three or four days. Extraordinary stories are told regarding the warmth of the Chinook, and we may well imagine what a welcome it receives when the preceding temperature has been 20° to 30° below zero. It is described as soft and balmy "like a summer zephyr."

## INSULIN ON THE DISTRICT.

THE work of the Cicely Northcote Trust has already been reviewed in our columns.[1] The Trust works in connexion with St. Thomas's Hospital, London, and in its sixteenth annual report, issued by the hon. secretary at 15, Chesham-street, Belgrave-square, S.W., an interesting account is given of the valuable after-care offered to diabetic patients requiring insulin. The subject of self-injection of insulin and its dangers has already been briefly discussed,[2] but the proper administration of the drug is far from being the only problem in the after-care of diabetics. These patients have to be supervised for an unlimited period; not only must they have a continuous supply of insulin, but sufficient income to obtain the necessary diet. Under the Trust's management the procedure is as follows: As early as possible the ward sister notifies the Northcote Trust worker of the probable date of discharge, and the dose the patient is needing, supplying when necessary a copy of the diet sheet. Very often special diabetic bread and biscuits and sufficient insulin for the patient to use for a week or two are given, together with a syringe, as no risks can be taken. But much planning hereafter is necessary to see that the supply is continuous. Even the need for accurate scales must be considered, and these have sometimes to be lent as they do not always form part of the household's equipment. Although the patients are instructed in the wards how to give their own injections, only in rare cases is it considered safe for this to be continued without supervision, and the services of the district nurses are enlisted to witness the injections. These injections are given twice daily, at 9 A.M. and 6 P.M., and as the patients may not have a meal until after they have had their insulin, these times have to be adhered to as rigidly as possible. This is sometimes no easy matter for the hard-worked nurse in a scattered country district.

---

[1] The Climates of the United States. By Robert De Courcy Ward, Professor of Climatology in Harvard University. Boston: Ginn and Company. 1925. Pp. 518. $4.00.

[1] THE LANCET, 1925, i., 828.

[2] THE LANCET, 1925, ii., 765 and 803.

The invariable recommendation for diabetic patients is that they "must have no cause to worry." Sometimes this means a complete change of environment—perhaps a visit to the country or sea—with the necessary proviso that insulin and diet shall be provided. The economic consideration needed may be illustrated by giving two fairly typical cases.

CASE 1.—The patient required a special expensive diet and insulin. She needed a room to live in, a fire and gas or oil to cook by. The budget for these simple necessaries worked out as follows: Insulin, 6*s.*; room, rent, and storage of furniture, 11*s.*; diet, as inexpensively worked as possible, 25*s.*; fuel, oil, 3*s.* This gave a total of £2 5*s.*, which left no margin for clothes, soap, and the hundred-and-one tiny things which are scarcely counted in the budgets of those who have no financial worries. At the time of the recommendation the patient's assured income was £1 10*s.* weekly. She was uninsured and therefore could not obtain the insulin through a panel doctor, and the guardians were unable to help because her income was over scale. Had the diet been no problem, the patient could have existed without undue worry; but with the expense of a special diet this became impossible.

CASE 2.—B, aged 12. Father, labourer in country district, two sisters in service, four other brothers and sisters at school. The family shares a cottage of three rooms and there are seven mouths to feed. B returned from hospital on a large dose of insulin and an expensive diet. He is a difficult little boy to feed in any case. The mother has not only to provide the diet, but to persuade him to take the correct quantity of the correct food at the correct time. This task was cheerfully faced by his busy mother, but the question of the provision of sufficient butter, eggs, cream, and bacon was a difficult one as it could not be met out of the family budget.

It is in such cases as these that the work of the Cicely Northcote Trust and similar bodies is invaluable and irreplaceable. Such workers require cordial support and assistance.

## PECULIAR PAIN IN APPENDICITIS.

*To the Editor of* THE LANCET.

SIR,—The following cases were recently under my care.

CASE 1.—Male, aged 55. No previous history of ill-health. When called to see him at 3 A.M. he complained of vomiting and a "pain in his stomach." His bowels had moved some hours previously. Pulse 70, temp. 98·2° F. Hernial orifices normal. He was lying on his back with both legs slightly flexed. His abdomen was slightly distended. There was no rigidity or tenderness, but on deep pressure over McBurney's point he complained of great pain. No swelling or tumour of any sort could be detected, and rectal examination revealed nothing abnormal. On percussion a tympanitic note was obtained all over the abdomen. On rotating the extended right leg internally (Cope's sign) there was no increase of the pain, but on internally rotating the extended left leg he complained of pain around the umbilicus. I gave him ¼ gr. of morphia by mouth and called to see him six hours later, when the vomiting had stopped, but the paroxysms of pain in the appendix region continued, but in a milder form. He still complained of pain around the umbilicus on internally rotating the left leg. A soap and turpentine enema gave good results. He was kept in bed for a week on a light diet, with one tablespoonful of liquid paraffin twice daily. Under this treatment the pain almost ceased and his bowels moved daily. Two weeks later he was perfectly well.

CASE 2.—Boy, aged 12. Previously healthy. When called at 10 A.M. he was lying in bed in the typical appendix attitude. He complained of pain in his right side and had vomited several times. Temp. and pulse were normal. His bowels had moved the previous day. On examination the only abnormality that could be made out was pain on deep pressure over McBurney's point. He also complained of pa around the umbilicus on internally rotating his left le He was given a glycerine suppository, and hot poultices we applied to the right side of his abdomen. At 4 P.M. the pa was less, the vomiting had stopped, but his temperatu was 99·4° F. and his pulse was 100, but the pain on internall rotating the left leg persisted. The parents refusing the consent to an operation, the boy was kept in bed for a wee on a light diet, with liquid paraffin when necessary. At th end of this time he was quite recovered.

Can any of your readers tell me if these were cases of tru appendicitis, or of what used to be called perityphlitis What is the explanation of pain around the umbilicus on rotating the left leg internally? I can find no reference to this sign in the literature.

I am, Sir, yours faithfully,

Dublin, Jan. 18th, 1926. SYLVIA B. WIGODER, M.D.

## INOCULATION FOR SMALL-POX.

*To the Editor of* THE LANCET.

SIR,—Dr. John Macqueen does not point out in his article (THE LANCET, Jan. 23rd, p. 212) that, although Lady Mary Wortley Montagu *may* have made fashionable in England after 1717 the practice of inoculation, others can lay claim to priority of description in this country. Weld, in his "History of the Royal Society" (1818), details the whole affair and draws attention to two early papers in the *Philosophical Transactions.* The first paper was published in 1714: An Account, or *History,* of the Procuring the Small Pox by Incision or Inoculation, being the Extract of a Letter from Emanuel *Timonius,* Oxon., & Batav, M.D., S.R.S., dated at Constantinople, December, 1713 (*Phil. Trans.,* xxix., April, May, June, 1714, pp. 72-82). The second paper is entitled: Nova et tuta Variolas excitandi per Transplantationem Methodus, nuper inventa & in usum tracta. Per Jacobum Pylarinum, Venetum, M.D. & Reipublicæ Venetae apud Smyrnenses nuper Consulem (*Phil. Trans.,* xxix., January, February, March, 1716, pp. 393–399). It was not until June, 1716, that Lady Mary's husband was appointed ambassador to the Porte, and in a letter to England, dated April 1st, 1717, she described the practice of inoculation as she had seen it at Adrianople.

I am, Sir, yours faithfully,

E. G. T. LIDDELL.

Trinity College, Oxford, Jan. 25th, 1926.

## OLD AGE MUST COME. . .

MUCH has been written and said of the increased expecta tion of life enjoyed by the child born to-day as compared wit 50 or 100 years ago. Life insurance tables have bee readjusted and public health activity has been credited wit the extra 10 years or more to which our grandchildre may look forward with some certainty. There is, however another side to the picture, and it is not only the cynics wh have declaimed against this attempt to postpone the inevitable end. The idea of an extra 10 years of enforced idleness after a busy and interesting life does not appeal to everyone, even if hobbies and other pleasant occupations can still be enjoyed, and on reading a booklet by a life insurance company dealing with the period of old age, the thought may arise that while insurance firms may have a certain interest in keeping us alive, there is something to be envied in those fortunate individuals who meet the "old man's friend," pneumonia. The primary object of Dr. Leonard Williams's latest pamphlet "The Sere and Yellow Leaf," issued by the Legal and General Assurance Society, Ltd., is to inculcate the idea of periodical health examinations, which commends itself to all health workers and is fully in keeping with the modern slogan of prevention. With his recommendation to the elderly man of walking and other exercises, and with his emphasis on cultivating outside interests, all sane people will be in agreement. Less convincing is the impression conveyed by Dr. Williams's remarks that comfort in old age is to be eschewed. "It is the fur-lined basket by the cosy fireside which is the real enemy of man," he writes. But is not this the just reward of the professional octogenarian? And if "therein lies the secret of the sere; therein lurks the canker of the yellow leaf," the restful autumn scene on the cover of the booklet should reassure any such who is beginning to feel uncomfortable in his fireside seat. Obviously a healthy old age will be more enjoyable than one troubled by sickness and disease which might have been prevented if discovered in time at a periodical medical examination, and this sentence contains all that the booklet intends to convey.

---

HOSPITAL AREAS IN EAST KENT.—A conferenc at Canterbury of representatives of the East Kent hosp has decided to appoint a joint committee for the delimit of areas and the collection of money, and to con arrangements for reciprocity of treatment.

# Some Clinical Aspects

OF

# SIMPLE GOITRE,

## WITH REMARKS ON ITS CAUSATION.

*Being the Hunterian Lecture delivered before the Hunterian Society on Jan. 25th*

BY SIR JAMES BERRY, B.S. LOND.,
F.R.C.S. ENG.,
CONSULTING SURGEON TO THE ROYAL FREE HOSPITAL.

IN the days of the great John Hunter the thyroid gland had but little interest for surgeons. It was thought to be an organ of little or no importance, its diseases were ill-understood, and surgical interference with it was hardly ever demanded. Hunter himself, I believe, never wrote anything about it. But one can easily imagine with what zeal and enthusiasm Hunter, had he practised in Switzerland at the present day, would have thrown himself into the fascinating study of the thyroid and its diseases. Their operative treatment, which modern methods alone have rendered feasible, would have been, I am sure, of special interest to him.

I do not propose, however, to speak to you of the operative surgery of the thyroid; I have already written and said much on various occasions upon this subject. But I desire to discuss some of the clinical aspects of that most common of all diseases of the thyroid—namely, simple or endemic goitre—and to deal also with its pathology and causation.

### VARIETIES OF GOITRE.

If we leave aside malignant disease, acute inflammation, and certain of the rare forms of thyroid enlargement, we are left with two main varieties of goitre. The first is characterised by excess of the cellular elements of the gland and by diminution or absence of colloid. This is exophthalmic goitre in its various forms. It appears to be essentially a hypertrophy of the gland, although this is probably not the whole explanation of the condition. Of this form of goitre I propose to say but little in this lecture. I have written about it before, and the main symptoms of the condition are well known.

The second variety is that of simple or endemic goitre, and the first point that I want to emphasise is that *simple endemic goitre is not a hypertrophy of the gland. It is essentially a degeneration.* The enlargement of the gland in the earliest stages in which I have been able to observe it consists primarily in a distension of the organ with colloid, with atrophy of the epithelial elements. In this respect it differs entirely from the goitre of Graves's disease, in which, as mentioned above, the enlargement is due to an increase in the cellular elements of the gland. This misuse of the term hypertrophy as applied to simple goitre is very widely spread in literature at the present day. It is especially found in the writings of experimental laboratory researches and in those of physicians, who presumably have fewer opportunities of seeing the inside of a goitre than have surgeons who operate upon them.

If the cause that produced the increase of colloid, almost certainly an irritant of some kind, be removed, the gland quickly returns to the normal. We see this frequently in practice. But if the cause persists, a fibrosis due to slight chronic inflammation sets in and the condition gradually becomes a permanent one. In goitres of considerable size or long duration this interstitial fibrosis may be most marked, and it is frequently accompanied by calcification. The retention of the colloid leads to the presence of small cysts which may coalesce into large ones. But nearly all the larger cysts of a goitre are formed by the breaking down of so-called adenomata. These "adenomata" are masses of ill-formed thyroid tissue, surrounded by a more or less well-marked capsule. On account of their encapsulation they play an important part in the operative treatment of goitre. The term "adenoma" is not a very correct one, but it is convenient for practical purposes. The same may be said of the term parenchymatous, which most surgeons, including myself, are in the habit of employing loosely for the general enlargement of the whole gland, as distinguished from local enlargement caused by adenomata.

### *Differential Diagnosis.*

It will thus be seen that the pathological picture of the two diseases, exophthalmic and simple goitre, is widely different. Similarly, their clinical features in typical cases are markedly dissimilar. Difficulties of diagnosis, however, arise occasionally in the early stages of both, as well as in those mixed cases which present some of the characteristic symptoms of both forms. For instance, the characteristic symptoms of exophthalmic goitre may supervene upon a pre-existing simple goitre. To this the term of "Basedowified" goitre is often applied, especially by continental and American writers. Similarly there are cases of simple goitre, especially of the adenomatous or cystic forms, which may show symptoms that are usually characteristic of the exophthalmic form—such as tremor. As long ago as 1907[1] I pointed out the existence of a group of thyroid cases which, then as now, I usually treat by operation. These display tremulousness, palpitation and some of the other symptoms of Graves's disease, but never exophthalmos. They are not cases of genuine exophthalmic goitre. Most of them are cases of more or less encapsuled tumours, cystic or solid. So far as my observations go, it is a goitre lying deeply behind the sternum which presents most often these misleading symptoms, and which is apt to be confused with true exophthalmic goitre. From an operative point of view they present few or none of the special risks attendant upon operation in cases of Graves's disease.

Many surgeons call them cases of hyperthyroidism, but I doubt whether this is really a correct term. In some the tumour is nothing but a cyst with a thick, fibrous wall or a solid mass of almost inert tissue, which can have little or no secreting action, and is certainly not a cause of hyperactivity. Some surgeons boldly include these cases in their statistics of exophthalmic goitre merely on the ground of persistent tachycardia, but I think this is quite wrong. Their inclusion leads to confusion and tends to impart an unduly rosy hue to statistics of operations. Certainly many such cases which really belong to the simple variety come to me with a ready-made diagnosis of hyperthyroidism or Graves's disease. It is important also to bear in mind that the not uncommon occurrence of a sudden hæmorrhage into a soft encapsuled adenoma may also produce a good deal of temporary tachycardia and irregularity of pulse, which produces a superficial resemblance to exophthalmic goitre. Acute catarrhal conditions may also sometimes have the same effect.

It should never be forgotten that a simple goitre may be accompanied by tachycardia which is not due to the goitre at all. I have seen numerous cases of this kind in which the tachycardia was due to an unsuspected lesion in the appendix, gall-bladder, uterus, or kidney. There appears to be but little doubt that septic foci in distant parts of the body may lead to a hyperplasia of the thyroid, but without colloid distension, and may be accompanied by tachycardia. Experiments on animals seem to confirm this view. It is noteworthy that all the forms of thyroid enlargement which were produced in animals by my friend Colonel R. McCarrison by food contaminated with fæcal matter appear to have been of the hyperplastic form only. He tells me that it was only when he added an excess of lime to the food that he succeeded in obtaining colloid distension of the vesicles.

---

[1] Proceedings of the Royal Society of Medicine, Section of Surgery, Nov. 12th, 1907, pp. 36, 37.

The *differential diagnosis* between early cases of simple goitre and Graves's disease, before any exophthalmos has set in, is often difficult. Points which assist are: in Graves's disease, excitability of the patient, aspect of the face, and a preference for cold weather rather than hot; while placidity and a dislike of cold are more characteristic of a patient suffering from simple goitre. A slightly subnormal temperature, which is raised to normal by small doses of thyroid extract, shows hypothyroidism, and confirms the diagnosis of simple goitre.

In concluding this part of my subject I may say that it seems to me evident that, as far as simple goitre is concerned, we are dealing not with hypertrophy or hyperplasia of the thyroid, *but with a condition that is essentially a degeneration*. This view is in direct opposition to that which seems to be adopted by most of those who perform experiments on animals without having had much opportunity of investigating the pathological conditions of the disease as it occurs in man.

[A series of pathological specimens and photographs was here shown to illustrate the gradual transition from the early colloid goitre, with but slight fibrosis, through mixed forms with adenomatous nodules, up to the later, completely degenerated fibrous or cystic forms, often with much calcification.]

### ENDEMIC GOITRE.

I now come to the next part of my subject—namely, endemic goitre. It may be asked why should a general surgeon like myself, who has practised all his life in London, venture to express any opinion on the conditions and causation of endemic goitre. I will explain. It is just 40 years ago since I first began to take an interest in goitre, when as a very young man I was working for the Jacksonian prize of the Royal College of Surgeons. After various investigations into the anatomy and pathology of the thyroid I spent many weeks wandering about different parts of Switzerland with note-book and camera in hand, talking to Swiss surgeons and country doctors, interviewing the subjects of goitre in Swiss villages, and examining pathological specimens in Swiss museums. Since that time during 35 years I have rarely passed a year without wandering for some weeks about Europe, usually on foot or bicycle. I have visited nearly every European country, most of them repeatedly, and wherever I went I kept my eyes open for goitre. Moreover, in the pursuit of geological studies and from love of climbing, I have often been on the higher Alpine glaciers both of Switzerland and Tyrol, on the rocky summits of the Pyrenees and the Carpathians, and amid the snowfields of Norway. In this country I may also claim that there is no county that I have not visited, and from which I have not obtained some information connected with the occurrence of goitre. I have at least enjoyed unusual opportunities for learning where goitre is common and, what is equally important for our purpose, where it does *not* occur.

#### *Causation.*

This leads me to a consideration of the difficult and much-discussed problem of the causation of endemic goitre. It is needless for me to mention the numerous theories that have from time to time been put forward on this subject. They are to be found in most text-books. One of the most complete modern summaries is that of Crotti in his excellent book on goitre.

But I must say a few words about a theory that has attracted a good deal of attention lately. This is the theory that a "lack of iodine" either in food or water (or even in the air!) is the essential cause of goitre. An immense amount has been written about this both by those who know something about goitre and by those who, from their own personal observation, know little or nothing, but who copy the remarks that have been made by others. This theory, the most fashionable one at the present day, and to my mind one of the wildest, is a revival of an old view, put forward at least 75 years ago, based upon the fact that iodine is a well-known remedy for some forms of goitre. This modern revival, which comes from America, seems to depend upon chemical investigations of normal thyroids and of the enlarged thyroids of goitre. It is asserted that a goitre contains less iodine than a normal gland. This may well be the case, but in itself does not prove anything as to the causation of goitre. It is quite possible that a certain intake of iodine may be necessary for health. There is also no doubt that in some diseased conditions of the thyroid gland iodine treatment is beneficial. But to deduce from this that absence of iodine is the main, if not the only, cause of endemic goitre is, to my mind, wholly unjustifiable and totally opposed to observed facts as to the distribution of the disease. I should not have thought it worth while to devote any time to this theory were it not that it has been widely accepted in this country, not only in medical circles but also by the lay press.

In the latest (1925) edition of so excellent a book as Taylor's "Practice of Medicine" we actually read: "It has been conclusively demonstrated that endemic goitre results from lack of iodine and tends to occur among people who live far away from the sea." The writer of this statement, like many others who maintain this theory, seems to have overlooked such facts as that goitre is far more common in the Maritime Alps of France, which are close to the Mediterranean, than in many places in the centre of that country far away from the sea. Moreover, it is by no means unknown close to the sea in South Wales and parts of the Italian Riviera, as well as in many other places on the sea-coast, as I can testify from my own observations. If this part of the theory were true we should expect to find the endemicity of goitre increasing steadily as we went inland. This is certainly not the case. As far as the other part of the theory is concerned, no one has ever shown that iodine is less common in notoriously goitre-producing waters than in waters that do not produce it.

The most convincing single proof of the baselessness of the "lack of iodine" theory is afforded by what occurred in connexion with goitre at Sanawar in North India, investigated by Colonel McCarrison and fully reported by him in the *British Medical Journal* of June 7th, 1924. At a large school in an institution at that place, where a high incidence of goitre had been present for many years, he found in 1913 that over 80 per cent. of the children were affected. By his advice a new and pure water-supply was introduced in 1918. In 1922 "goitre was reported to have disappeared from the school." In the autumn of 1923, when he revisited the school, the incidence of goitre was only "2·2 per cent., or no greater than the incidence of thyroid enlargement among school-children residing in a non-goitrous district such as Delhi." He was assured by the principal that no changes had been made in the food. Samples of the new water-supply were analysed by the chemical examiner to the Punjab Government, who reported that it contained no iodine. Not satisfied with this, Colonel McCarrison "caused 25 gallons of the water to be evaporated to dryness after the addition to it of sodium carbonate. The residue thus obtained was sent to the chemical examiner for estimation of its iodine content. He reported that it contained no iodine." It was clear, therefore, "that the disappearance of goitre was not due to an increased intake of iodine either by way of the new water-supply or of food." Surely this well-attested instance of endemic goitre, ended by the introduction of a water-supply devoid of iodine, should alone be enough to demolish the "lack of iodine" theory altogether.

#### *Geological Considerations Bearing on Endemic Goitre.*

I turn now to some geological considerations which are, I think, not without importance in connexion with our subject. I will first of all point out where the great centres of endemic goitre throughout the world are to be found, places where in some parts everybody has goitre to a greater or less extent. [Maps were here shown.] In Europe there is a good deal in the Pyrenees, and then along the whole length of the Alps, from the Maritime Alps, through Savoy and right along the Swiss and Italian Alps and far into Eastern Austria, gradually decreasing until we come to the great Hungarian plain from which, as far as my observations go, goitre is, in the main, absent. In the northern parts of the Carpathians I have seen but little of it, but in Transylvania there is again a good deal. It must be noticed, however, that it is not so much in the higher regions of all these mountains that goitre is most prevalent, but rather in their lower parts and in the foot hills that slope away from the central axis. In the case of Switzerland, so far as published maps are concerned, and in this respect my own limited observations tend to confirm them, it is in the lower portion of the upper Rhone Valley above Martigny, and in the cantons of Berne, Fribourg, and Aargau, that the disease is most prevalent. Passing on into Asia, although no maps of goitre distribution (so far as I am aware) have been published, I have overwhelming information, both from published and private sources, that goitre is extremely prevalent along the whole length of the Himalayas from Cashmere to Assam and beyond and on the lower ground sloping away from these mountains, and even sometimes far out into the plains The Andes, the Cordilleras, and the Rocky Mountains in America, as well as the Alps of New Zealand, are notable centres of endemic goitre All these mountains are, as every geologist knows, young mountains in the geological sense—i.e , mountains in which active denudation or erosion is taking place In the composition of practically all of them there is much limestone.

Turning for a moment to other mountains, there are three groups on which goitre is not markedly prevalent First, the older worn-down mountains, where the process of denudation is usually only slightly active and which are mainly the remnants of vanished higher ranges An instance of this is seen in the Highlands of Scotland Secondly, the older crystalline rocks, seen, for example, in Western Norway Thirdly, mountains composed entirely of volcanic rocks, such as active and extinct volcanoes It is worthy of note that the two last varieties possess *no limestone*

Let us return now to the characteristics of the younger mountain chains already mentioned, in most of which endemic goitre abounds. Most of them are crowned by glaciers, especially in the regions where goitre is most common No student of geology need be reminded of the constant grinding and denuding action of these slowly moving rivers of ice. Even the casual traveller in Switzerland must have noticed the turbidity of these glacial rivers that bring down into the lakes an immense amount of mineral matter in the form of finely ground up rocky material in suspension. He can scarcely have failed to notice the discoloration of the water of all the Swiss lakes, varying in hue from a greenish tinge to the beautiful blue of Lake Geneva. This discoloration is due, of course, to the extremely fine sediment suspended in the water How different from the mechanically pure and therefore clear waters of the lakes of such a mountainous country as the Highlands of Scotland, the geologically old mountains already alluded to This is possibly, I might say probably, one of the reasons why Glasgow, which gets a pure supply of water from a highland lake, is immune from goitre A similar state of affairs seems to exist in the Himalayas Over and over again do we read of the turbidity of the waters descending from these mountains.

But it must not be supposed that I am claiming that glaciers are essential to the production of a goitre-producing water In Switzerland plenty of the smaller streams and springs do not come directly from glaciers. Many of them come from the great accumulations of glacial debris overlying the central plain of that country, or from the great series of sandstone and limestone that underlie it. On a smaller scale erosion and consequent sedimentary pollution of streams occurs in any hilly country where the rocks are comparatively soft and easily eroded, as in the case of calcareous marls and many others.

The geological structure of the rocks on which goitre occurs is a very difficult subject into which I cannot now enter It must suffice to say that there is in general a connexion between the distribution of goitre and the water derived from calcareous soils of various kinds But many errors have arisen from hasty conclusions drawn merely from a comparison between geological maps and those of goitre distribution It is the water derived from these rocks and not the geological names of the geological formations that we have to take into consideration. England is not a very good country for the study of the geological distribution of goitre, partly for the above reason Partly also because of the widespread distribution of the disease throughout this country, and the complex geological structure of the land, which has led to the description of the country as the paradise of geologists, since practically no formation is unrepresented All this makes the study particularly difficult.

To my mind there is abundant evidence that the *cause of endemic goitre is to be found in drinking* water, and though I fully admit that the actual nature of the poison is not definitely proved, I am inclined to think that in the minute particles of inorganic mineral matter (probably calcareous), suspended in the water, we find, even if not the actual poison, at any rate an essential accompanying factor When visiting various goitrous districts I have been struck by the frequency with which the disease occurs among people who habitually drink turbid waters, and time after time I have been told the same story—that in certain districts goitre has disappeared or has greatly diminished since the introduction of a new and better water-supply Undoubtedly much more attention is directed nowadays to the importance of the water-supply in connexion with endemic goitre, but whether the action taken in consequence is always wise is questionable. For instance, the adoption of the "lack of iodine" theory by medical officers of health has led to the practice of adding iodine to public water-supplies both in America and Switzerland and also in this country Whether this is a good method of administering iodine for the prevention or cure of goitre has led to much controversy both here and abroad. Some advocate the alternative method of giving it in sweets or chocolate to school-children, or adding it to salt. This practice of the *indiscriminate* administration of iodine, though it may be suitable to places with high endemicity like many parts of Switzerland, is hardly necessary in England.

I may refer to an excellent paper on the subject by Dr James Wheatley,[1] M.O.H for Shropshire, who gives the preference to the iodisation of salt, and to another by Sir Alexander Houston,[2] Director of Water Examinations, Metropolitan Water Board. It is to be regretted that both these writers appear to accept fully the lack of iodine theory There is at least some evidence that iodine poisoning may occur from the indiscriminate administration of iodine

### CONCLUSIONS.

In conclusion I will sum up the points upon which I have tried to lay stress, as follows:—

1. Simple endemic goitre is not a hypertrophy but essentially a degeneration of the thyroid gland. The gland is not over-active, but under-active.

2 Whatever may be the connexion between iodine and the thyroid gland, there is no reason for believing that a lack of iodine has anything to do with the causation of endemic goitre, as found in the human subject.

3 It is quite certain that, at least in the vast majority of cases, the disease is produced through the *agency of drinking water*

4 There is much evidence that practically all waters which produce goitre contain frequently,

---

[1] Journal of the Royal Sanitary Institute 1926, xlvi., No 7

[2] The Medical Officer, Jan. 24th, 1925, p 41

although not necessarily at all times and seasons, mineral matter in suspension, usually in an extremely fine state of subdivision.

5. There is also a good deal of evidence that this mineral matter is generally of a calcareous nature.

6. Organic matter in suspension, although capable apparently of causing a hyperplasia of the gland, at least in animals, has not been proved to be the cause of endemic goitre as seen in man.

# NEW FACTS CONCERNING THE FAT-SOLUBLE VITAMINS.

*Delivered at a Meeting of the Section of Comparative Medicine of the Royal Society of Medicine on Jan. 27th, 1926,*

BY J. C. DRUMMOND, D.Sc., F.I.C.,
PROFESSOR OF BIOCHEMISTRY IN THE UNIVERSITY OF LONDON.

CONSIDERABLE progress in the study of the fat-soluble vitamins has been made since McCollum and Osborn and Mendel in 1913 first observed the marked influence on growth which certain animal fats exhibit in contrast to the inactivity of the majority of vegetable oils.

For a number of years it was considered that this physiological action of animal fats was due to the presence of a substance to which the name "fat-soluble A" was given. It was demonstrated quite clearly by extensive experiments in America and Great Britain that this substance, whatever its nature, is essential for the growth and well-being of young animals, but it was not until E. Mellanby carried out his well-known researches on the causation of rickets that the influence of certain foodstuffs in facilitating the deposition of lime in developing bone was traced to a dietary factor of the same type.

### *The Ætiology of Rickets.*

It will be remembered that at the time Mellanby published his researches there were two conflicting schools of thought regarding the ætiology of rickets. On the one hand a considerable number of authorities regarded the disease as being primarily due to defective hygienic surroundings, in particular lack of sunshine and exercise, whilst on the other certain observers were inclined to regard it as due to defective diet. The experiments of Mellanby made it clear that rickets can be produced at will in experimental animals by depriving them of a dietary constituent similar as regards its distribution in natural foodstuffs and its general properties to the vitamin that had been discovered by the American investigators in 1913.

Mellanby was careful not to assume the identity of the two factors, and for a period there was some confusion in the minds of scientists as to whether the growth-promoting and antirachitic properties of a foodstuff such as cod-liver oil were due to one or more than one factor.

We owe it to the researches of McCollum at Johns Hopkins University, Baltimore, that a clear differentiation between the substances responsible for these two effects was made. McCollum demonstrated that the rate of destruction of the growth-promoting and antirachitic potency of cod-liver oil were destroyed at very different rates by subjecting the oil to oxidation. Furthermore, he ascertained that certain natural foodstuffs may show powerful activity in preventing rickets without any marked effect on growth or vice versa. It appeared very probable, therefore, that at least two substances of the fat-soluble vitamin type occur in cod-liver oil, and for purposes of classification these are to-day termed vitamin A and vitamin D, the former term being applied to the substance more particularly affecting growth, and the latter referring to the factor playing a part in the deposition of lime in bones.

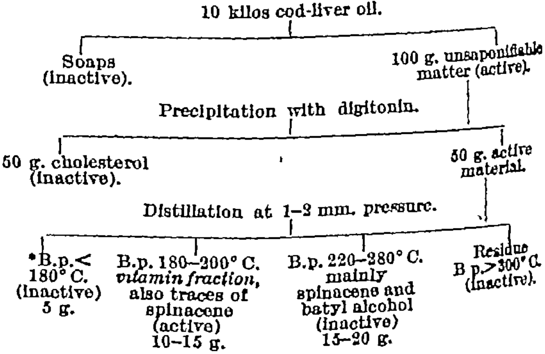
### *A New Fat-soluble Vitamin.*

Before passing on to consider in detail recent investigations regarding these two interesting subjects, I should like to draw attention to the important researches by Prof. H. E. Evans, of California, which have proved the existence of a third vitamin of the fat-soluble class playing an extremely important part in reproduction. As yet information concerning the chemical nature of this substance is meagre, but in my laboratory we have satisfied ourselves that the factor discovered by Evans is distinct from either vitamin A or D, and we have confirmed his main conclusions regarding its action. This newly discovered factor is now termed vitamin E. It is, I think, a most interesting fact that the attention of both biochemists and physiologists is at the present time being turned away from the true fats themselves, and is being directed to the examination of the small traces of substances which usually accompany the glycerides as they occur naturally.

It will be remembered that the majority of natural oils and fats, such as cod-liver oil, consist of about 99 per cent. true fats—i.e., glycerides—and some 1 per cent. substances which resist the action of potash when fats are broken down into glycerol and soap in the ordinary saponification process. This 1 per cent. is termed the unsaponifiable matter. In the past this fraction has attracted very little notice, and interest has centred entirely round the digestibility and nutritive value of the large proportion of true fats present in the oil. The discovery that the unsaponifiable fraction, if prepared with care so as to prevent secondary changes, in particular oxidation, occurring, contains the whole of the vitamins present in the original oil has, as I say, diverted attention to the examination of this fraction.

### *The Nature of Vitamin A.*

I will first bring to your notice some few details of our own attempts to isolate and to determine the nature of the vitamin A, which appears to be largely responsible for the beneficial influence which cod-liver oil has on growth. The unsaponifiable matter prepared from cod-liver oil has been submitted to chemical fractionation according to the scheme given below:—



10 kilos cod-liver oil.
Soaps (inactive).
100 g. unsaponifiable matter (active).
Precipitation with digitonin.
50 g. cholesterol (inactive).
50 g. active material.
Distillation at 1–2 mm. pressure.
*B.p.< 180° C. (inactive) 5 g.
B.p. 180–200° C. vitamin fraction, also traces of spinacene (active) 10–15 g.
B.p. 220–280° C. mainly spinacene and batyl alcohol (inactive) 15–20 g.
Residue B.p.>300° C. (inactive).

* B.p. = boiling point.

From this table it will be observed that we have succeeded in separating the active substance from a number of other constituents of unsaponifiable matter, but I regret to say we have not yet achieved the separation of the vitamin A in what can be considered to be the pure condition.

Some of you will recall a statement in the lay press a few weeks ago that the Japanese investigator, Takahashi, had succeeded in isolating vitamin A as a pure compound. We have critically examined his work and have satisfied ourselves that his preparations are not more pure than those which we have obtained. It may be of interest to discuss the rather extraordinary potency of the preparations which have been obtained by this fractionation.

The experimental animals employed in these investigations are usually rats. A rat of 100 g. body-weight will consume during the day approximately 15 g dry weight of food. If this food be deficient in vitamin A the animal will completely fail to grow, and in due course will decline in weight and die. In order to keep the rat alive, to maintain health, and to permit a normal rate of growth it is only necessary, as we have found, to supplement his deficient diet with an amount of active fraction weighing 1/200th mg You will, I think, agree with me that this dosage is of so small an order as to recall the effective doses of internal secretions and of certain drugs.

I fear I cannot give any clear idea, as yet, of the chemical nature of vitamin A, but the very highly active fractions we have obtained largely consist of unsaturated higher alcohols, containing in their molecules only the elements carbon, hydrogen, and oxygen. It is possible that the vitamin is actually one of these alcohols, but until we have prepared it in undeniably pure condition it would be unwise to draw such a conclusion It will be agreed, at any rate, that we must abandon all ideas of the vitamin being a labile, ill-defined compound as we at one time imagined, when it is so readily demonstrated that it can survive such drastic chemical treatment as saponification with boiling alkalies and distillation at temperatures over 200° C

I will not say more about vitamin A beyond mentioning that Dr O Rosenheim and I have recently described a simple colour reaction that we believe is caused by it and which is proving of great use in detecting the presence of the active substance. I must now pass on to give a brief review of

### *Recent Knowledge concerning Vitamin D*

As pointed out above, McCollum's work clearly differentiated vitamin A from vitamin D, but this advance did not at once help to reconcile the two conflicting schools of thought regarding the causation of rickets. The reconciliation seems to-day to have been accomplished and the story of its achievement is one of the most fascinating which recent scientific progress has presented.

In 1919 Huldschinsky observed that children suffering from rickets were rapidly cured on exposure to sunlight, or to the light of lamps which emit rays in the ultra-violet part of the spectrum. This striking observation soon received general confirmation, and some glimpse was then obtained of the line upon which one might correlate the views of the two opposing groups of scientists But, welcome as some prospect of clearing up this difficult matter was there still remained the task of determining why rickets could be cured equally well by exposing the patient to ultra violet light or by administering a substance such as cod liver oil

The first clue that led to a solution of this problem was provided by the careful work of the American investigator Steenbock, who discovered the remarkable fact that a food mixture which, by reason of its deficiency will give rise to rickets in animals, becomes endowed with antirachitic potency after it has been exposed to ultra violet light. Two possibilities suggested themselves to account for this On the one hand, it was possible that the treated fats absorbed ultra violet rays, and that the energy so absorbed was later emitted in the form of secondary radiations, which effected a curative action similar in character to that produced by direct exposure to the primary radiations. On the other hand—and it seemed a more attractive hypothesis—it was possible that the absorption of the short wave length radiation actually produced in the foodstuffs a substance of the type of antirachitic vitamin D It was comparatively an easy matter to examine one by one the constituents of the food mixture, and this examination soon revealed that the precursor of the physiologically active substance is present in the oil or fats The examination of such activated fats revealed that the conference of antirachitic potency could be traced to the action of ultra violet light on a constituent or constituents of the unsaponifiable fraction One of the most commonly occurring substances in these unsaponifiable oils and fats is the familiar substance cholesterol—a substance of almost universal distribution in living cells

Dr Rosenheim and Mr T A. Webster and I were able to show, simultaneously with Steenbock and Hess in the United States, that cholesterol, or the very closely related compound, phytosterol, is the parent substance of the antirachitic vitamin. It is possible to take the purest specimens of cholesterol—and it is a substance which can be prepared in a state of considerable purity—to expose it to ultra violet light for an hour or two under suitable conditions, and to obtain thereby a product showing an extremely powerful antirachitic action. This activated cholesterol, if we may so term it, shows little or no effect on growth, nor does it show other properties of vitamin A, so that it may now be definitely accepted that these two substances A and D are distinct.

As yet the chemical investigation of the substance produced from cholesterol by the action of ultra-violet light has not revealed the chemical nature of the active substance It should, however, prove possible to obtain a fairly large amount of this material, to fractionate by some such process as I have already described, and then to obtain the antirachitic substance in a pure state and ascertain its nature and properties.

I have presented these questions very much from the biochemical aspect I have done this because I am in my own researches primarily concerned with the biochemical problem of determining the chemical nature of these remarkable substances and ascertaining their physiological action, and I shall be satisfied if I have made clear the following points

In the first place, there can be no question, I think, that there has been satisfactory differentiation between these two fat-soluble vitamins A and D and that both of them appear to be physiologically efficient in amounts so minute compared with the quantities of ordinary foodstuffs that are required by the body that in looking for parallels one can only call to mind the action of agents such as the secretion of the thyroid gland or of certain drugs In the second place, I rather hope that I have dissipated from the minds of any who still retain it the old and erroneous idea that the vitamins are hypothetical substances, or that, if they exist, they are substances of ill defined character comparable with the enzymes or the toxins

# TUBERCLE BACILLI IN FÆCES

## A NOTE ON THE EXAMINATION OF THE FÆCES OF 225 TUBERCULOUS CHILDREN *

BY KATHLEEN A. H. SYKES, M.D LOND

THAT many patients swallow a large proportion of their sputum has long been recognised. This is especially true of women and children, but, owing to the frequent difficulty of diagnosis in children, the importance of obtaining definite evidence of tuberculosis, either by examination of the sputum if it can be obtained, or by other methods if it cannot, is obvious, and hence any method which will help to this end is of value. The results which have been obtained by examination of the fæces for tubercle bacilli in this series of cases are such as to show that this method is of importance, and should be more widely known and practised.

A number of workers have endeavoured to examine swallowed sputum as it is at length excreted mixed with fæcal matter in adults, but Inman,[1] in 1910, first applied this method to children. He examined the stools of seven children under 10 years of age, and found tubercle bacilli in one case from which no sputum could be obtained. He remarked that "the method suggests itself as particularly useful in the investigation of children," but added these results are too few to admit any conclusions being drawn from them." Emerson,[2] in 1913, wrote that "the diagnosis of pulmonary tuberculosis has been made in this way—i.e., by finding tubercle bacilli in the fæces—especially in children." Chandler and Stobo[3] in a recent paper emphasise the value of this method of examination, but only five children are included in their short series of cases.

---

* Being an abstract of a thesis accepted for the degree of M.D Lond , and published with the consent of the authorities of London University

For the purpose of this investigation over a period of 12 months (July, 1923–July, 1924) all cases admitted under the writer's care either for observation for suspected pulmonary tuberculosis, or with a diagnosis definitely implicating the lung, have had their fæces examined for tubercle bacilli as a routine. In addition, and as controls, a number of cases of tuberculous peritonitis, cervical adenitis, and children not suffering from tuberculous disease have also been investigated. In all a total of 225 cases have been examined, the ages of the children varying from 2 to 16 years.

### *Technique.*

The methods that have been employed are:—

(*a*) Examination of direct smears from the surface of constipated stools.

(*b*) Concentration methods.

1. Examination of the deposit after a small piece of fæces has been thoroughly mixed with normal saline and then centrifuged.

2. Examination of the deposit both with and without centrifugation after a portion of fæces has been treated for two hours with antiformin.

3. Examination by ligroin method. This method is carried out as follows: A piece of fæces the size of a walnut is ground up in a mortar with sufficient saturated solution of sodium chloride to produce an emulsion of the consistency of cream. To this emulsion 2 c.cm. of a mixture of 1 part of ligroin and 2 parts of acetic ether are added and the whole intimately mixed, then filtered through three layers of sterile gauze into a clean test-tube and allowed to stand for 20 minutes. With a sterile pipette a few drops of the layer immediately beneath the ligroin acetic ether layer are withdrawn, expressed on to a slide, spread and fixed by heat. This method is a modification of that first used by Lange and Nitsche.[4]

*Staining of Slides.*—The slides were stained with warm carbol-fuchsin solution for eight minutes, washed, decolorised in 25 per cent. sulphuric acid solution for one hour, washed, and then decolorised in absolute alcohol for 15 minutes, after which they were washed and counter-stained with methylene-blue.

The direct method (*a*) has been found unreliable when tubercle bacilli are scanty. The antiformin method, though reliable, is protracted. The ligroin method has been found reliable and convenient, and is recommended. No slide has been pronounced positive until at least three typical tubercle bacilli have been seen, and in doubtful or negative cases a search for at least 20 minutes has invariably been made.

### *Evidence as to the Bacilli found in Fæces being Tubercle Bacilli.*

At one time there was a widespread belief that human fæces contain non-pathogenic acid-fast bacilli. Fried[5] says "that this belief has no foundation," and Alexander,[6] as a result of his investigation states that "the inference follows that all acid-fast bacilli in the fæces are tubercle bacilli."

From the present research it would appear that the acid-fast bacilli found were tubercle bacilli for the following reasons:—

1. No other common bacillus will retain the carbol-fuchsin stain after one hour in 25 per cent. sulphuric acid followed by 15 minutes in absolute alcohol. The *B. lepræ* and the bacillus of Johnes' disease in cattle are stated to share this property, but they may be discounted in connexion with the cases here investigated.

2. *Animal Inoculation.*—Dr. S. Roodhouse Gloyne, pathologist at Victoria Park Hospital, very kindly carried out this special examination for me, and I take this opportunity of expressing my indebtedness to him.

Small portions of fæces from three patients in whom the fæces showed acid-fast bacilli but from whom no sputum could be obtained were forwarded to Dr. Gloyne, who inoculated guinea-pigs with them. In one case the guinea-pig died five weeks later from tuberculosis. In the second case the guinea-pig remained healthy, and on examination six weeks after inoculation showed no tuberculous lesions, but the patient subsequently coughed up sputum which contained tubercle bacilli, so the presumption is that the acid-fast bacilli found were tubercle bacilli, and that either the portion of fæces inoculated was free from these bacilli, or that they failed to infect the guinea-pig owing to some other reason. In the third case four guinea-pigs were inoculated on two separate occasions, but died of *B. coli* infection within 48 hours, so that a sufficient period did not elapse in which tuberculosis could develop.

3. All cases whose sputum contained tubercle bacilli showed acid-fast bacilli in the fæces, and no case in which the sputum was negative for tubercle bacilli on repeated examination ever showed acid-fast bacilli in the stools.

4. *Food.*—It has been suggested that acid-fast bacilli in fæces may be derived from certain foods, particularly milk and butter. The diet of this series of cases included milk, margarine, and, in some cases, butter, but in no case of tuberculous peritonitis, adenitis, or patients not clinically tuberculous (controls) who were taking a similar diet were acid-fast bacilli found in the fæces.

5. *Post-mortem Evidence.*—Two patients who never coughed up any sputum, but whose fæces showed acid-fast bacilli, came to post-mortem examination. Both cases showed typical tuberculous lesions of the lung, and in one case smears from the tuberculous lung showed tubercle bacilli. A smear was not taken from the lung in the second case.

6. *Subsequent Evidence from Sputum.*—Three patients whose fæces gave a positive result, but from whom no sputum had been obtained up to the time of this examination, subsequently coughed up sputum containing tubercle bacilli.

Further confirmatory though less substantial evidence is obtained from a study of certain of the cases. Thus in 25 patients from whom no sputum could be obtained, but whose fæces showed acid-fast bacilli, the signs and symptoms of pulmonary tuberculosis were sufficient to warrant this diagnosis. As is shown later, the subsequent course of such cases is very similar to that of those whose sputum contained tubercle bacilli.

### *Evidence as to the Source of the Acid-fast Bacilli being Tuberculous Areas in the Lungs.*

Rittel-Wilenko[7] holds that ulceration of the intestines is almost always found where acid-fast bacilli have been discovered in the fæces. Twenty-eight of the 54 cases she investigated came to autopsy, but it has been pointed out by other writers[8] that in such advanced cases 71–81 per cent. show intestinal ulceration whether acid-fast bacilli have been found or not, so that the evidence she submits is not convincing. Other writers[9] consider that "the occurrence of tubercle bacilli in the fæces is independent of an intestinal lesion"; while Fried thought that such an occurrence might have a double origin either from the discharges from an intestinal ulcer or from swallowed sputum.

That intestinal ulceration is not necessarily the source of such bacilli is shown by the case of M. K., who had moderately extensive disease of the lungs, but no sputum could be obtained from her. Her fæces contained acid-fast bacilli. Three weeks after examination of the fæces she died of tuberculous meningitis. The post-mortem examination, beside confirming the diagnosis of tuberculous meningitis, showed that the left lung was infiltrated with tubercle, the apex of the upper lobe showing commencing cavitation, and the right upper lobe was also tuberculous. Smears from the cut surface of the tuberculous area showed tubercle bacilli in abundance. On careful examination no lesion of the intestinal tract could be found.

That tuberculous ulceration of the intestine need not necessarily give acid-fast bacilli in the fæces is demonstrated by the case of M. B. In this patient disease of the lung had not been suspected during life, the child had never been known to cough while under observation, and had had no blood or mucus in her stools. The fæces were twice examined with a negative result each time. She died, and at the post-mortem examination numerous tuberculous ulcers were found in the intestines. At the apex of the left upper lobe there were some small cavities filled with dry semi-caseous contents which showed tubercle bacilli on microscopic examination. Apparently the lung disease was quiescent, and therefore no sputum was being swallowed.

Alexander[4] examined the fæces of six patients with tuberculous glands, and of these two gave a positive result. In these two cases the glands were noted as being "very caseous," but no note is made as to the condition of the lungs. The writer has examined the fæces of five cases of tuberculous glands without lung involvement, in two of which tubercle bacilli had been found in pus aspirated from the glands, and all five cases were negative. Ten cases of tuberculous peritonitis without lung involvement were also examined and these proved negative also.

Various authors have referred briefly to a variation of the number of acid-fast bacilli in the fæces corresponding to variations in the amount of sputum swallowed per day. The case quoted above (M. B.) rather bears out this point of view, and the following case is also confirmatory. This patient (S. B.) coughed up some sputum containing tubercle bacilli on one occasion prior to admission. Ten weeks later she was admitted to hospital, and on examination her general condition was found to be good, she had no cough nor sputum, and the examination of her fæces was negative. Nine months later she had a relapse with cough and general malaise, but no sputum. Her fæces were now found to contain acid-fast bacilli.

It is not unusual for children whose sputum has shown tubercle bacilli to cease to expectorate as their condition improves although cough may persist. In such cases I have found acid-fast bacilli persisting in the fæces for periods up to 11 months after the last specimen of sputum had been obtained.

### *Discussion.*

A study of the evidence submitted shows that there is little doubt that the acid-fast bacilli found in the fæces of children suffering from pulmonary tuberculosis are tubercle bacilli. Further, it would appear that in the majority of cases in which bacilli are thus found they are derived from sputum which has been swallowed. The possibility of such bacilli being derived from tuberculous ulceration of the intestine had been considered, and though the evidence is small, it is such as to suggest that this is not frequently the source.

### *Analysis of the Cases Investigated.*

1. *Sputum T.B.+. Fæces T.B.+.*—Fifty-two cases were investigated. In all these cases the physical signs were well marked, the sputum contained tubercle bacilli, and acid-fast bacilli were present in the fæces.

2. *Sputum previously T.B +. Subsequently no Sputum for not less than two months. Fæces T.B.+.*—Five cases examined, all of whom showed definite clinical signs. Their sputum had contained tubercle bacilli, but they subsequently improved, and had not expectorated for a period of not less than two months. Acid-fast bacilli were found in the fæces at intervals at 2, 2, 5, 10 and 11 months after the last positive sputum result.

3. *Sputum T.B. 0. Fæces T.B.+. Sputum subsequently T.B.+.*—One case. This child had signs of disease of the apex of the left upper lobe. The sputum when first examined showed no tubercle bacilli, but the fæces 25 days later contained acid fast bacilli. A specimen of sputum containing tubercle bacilli was obtained three months after examination of the fæces.

4. *No Sputum. Fæces T.B.+.*—Twenty-seven cases. Of these 18 had definite signs of pulmonary tuberculosis, in six others the signs were well marked, but were indicative of fibrosis of the lung, and in the remaining three the physical signs were slight, but suggested the probability of a lesion of the lungs. At the time of the examination sputum could not be obtained from any of these cases, but the fæces showed acid-fast bacilli in all. Three of the cases coughed up sputum containing tubercle bacilli subsequently, the interval after the examination of fæces being three days in one case, 21 days in the second case, and 41 days in the third case.

5. *Sputum had been T.B.+, but was T.B. 0 at time of Examination. Fæces T.B. 0.*—In three cases with well-marked physical signs over the greater part of both lungs tubercle bacilli had previously been found in the sputum. At the time of examination the sputum did not contain tubercle bacilli, nor were acid-fast bacilli discovered in the fæces. The interval between the T.B.+ sputum result and the examination of the fæces was one month in the first case, two months in the second, and seven months in the third.

6. *Sputum absent, but previously T.B.+. Fæces T.B. 0.*—Five cases, all with definite clinical signs. In these cases the sputum had contained tubercle bacilli, but at the time of the examination these patients were not coughing up any sputum. The fæces gave a negative result in all. The intervals between the T.B.+ sputum result and the examination of the fæces were 1, 3, 4, 11 and 11 months.

7. *Sputum T.B. 0, subsequently T.B.+ once. Fæces T.B. 0.*—In one case in which the signs were those of a pleural effusion on the left side both sputum and fæces examination gave negative results, but three months later this patient coughed up sputum containing tubercle bacilli.

8. *Sputum T.B 0. Fæces T.B. 0.*—In 31 cases in which the sputum examination was negative for tubercle bacilli the fæces also gave negative results. Of these cases 11 had evident physical signs upon which the diagnosis of pulmonary tuberculosis was made; in 12 the signs were those of fibrosis of the lung; in eight the only physical signs present were slight impairment of percussion note at one or other apex with in some cases altered breath sounds.

9. *No Sputum. Fæces T.B. 0.*—In 50 cases from whom no sputum could be obtained the examination of the fæces proved negative. In 10 of these the lung signs though not extensive were evident; 25 gave signs of fibrosis of the lung, and in 15 the only physical signs present were some alteration of the percussion note at one or other apex with, in some cases, weakened breath sounds.

10. Ten cases of tuberculous peritonitis, without lung involvement, were examined, but in all the result of the examination of the fæces was negative.

11. Five cases of tuberculous cervical glands, without lung involvement, gave a negative result on examination of the fæces. In two of these pus aspirated from the glands contained tubercle bacilli.

*Controls.*—Twenty-nine cases. A number of patients, suffering from other diseases or with no physical signs of disease, were examined as controls, and in all these the results obtained from the fæces were negative. In the majority no sputum was being expectorated, but in those with sputum the examination of the sputum was made with a negative result. The following is a list of these cases.

One case of bronchiectasis. Sputum T.B. 0.

One case of thickened pleura following a pleural effusion four years before. Sputum T.B. 0.

Three cases with no physical signs. Sputum T.B. 0.

Thirteen cases with no physical signs of disease and no sputum.

Eleven cases suffering from other disease such as enlarged tonsils and adenoids (1), bronchitis (1), pyonephrosis (1), rickets (1), congenital morbus cordis (1), debility (1), congenital syphilis (1), tuberculous dactylitis (1), and thickened pleura (3 cases). In all these cases no sputum was available.

### *Value of the Method in Diagnosis.*

A study of the analysis of the cases shows that in 100 per cent. of cases in whom the sputum consistently showed tubercle bacilli such bacilli were demonstrable in the fæces. Further, in no case in which the sputum result was negative on repeated examination could tubercle bacilli be found in the fæces.

The fæces of 85 cases gave a positive result, and of these 57 showed tubercle bacilli in their sputum at the time of the examination of the stools, and in four other cases tubercle bacilli were subsequently found in the sputum. Thus of the 85 cases 61 gave a positive sputum and fæces result, and 24 a positive fæces result only. In the majority of these patients the symptoms and physical signs were sufficiently marked as to leave little doubt as to the diagnosis, but the advantage of obtaining definite confirmatory evidence when no sputum is available in such a high proportion of cases (24 out of 85) is sufficiently obvious to need no stressing.

Where the clinical signs are not so definite the results of the examination still show its value. Thus of the 225 cases examined 181 were diagnosed on clinical grounds as suffering from pulmonary tuberculosis, or were under observation for suspected pulmonary tuberculosis. Of these 70 showed tubercle bacilli in the sputum at one time or another—a percentage of 38·6, while 85 showed tubercle bacilli in the fæces—a percentage of 40·9.

No case which clinically showed no sign of pulmonary tuberculosis gave a positive result on examination of the fæces.

The differential diagnosis between non-tuberculous fibrosis of the lung and pulmonary tuberculosis in children is often one of considerable difficulty. In this series 37 cases were diagnosed on admission as fibrosis of the lung, but six of these on examination showed T.B. in the fæces, thus helping considerably in settling the diagnosis and treatment. It would appear therefore that the main use of the method in future will be in helping to establish the diagnosis in cases of suspected pulmonary tuberculosis and in differential diagnosis. The diagnosis of tuberculous ulceration of the intestine by this method would not appear to be reliable.

### *Value in Prognosis.*

It has been shown above that in a proportion of cases the sputum at one time had contained tubercle bacilli, but at the time of examination did not do so, and yet tubercle bacilli were demonstrated in the fæces at periods extending to 11 months after the last T.B. sputum had been obtained. In such cases the symptoms, physical signs, and progress of the patients were such as to suggest that the lung disease was quiescent. These findings tend to show that an expression of opinion as to quiescence of the disease as judged by symptoms, physical examination, and absence of sputum should be given only with extreme caution. Examination of the fæces should be included in the factors to be considered in giving an opinion as to the advisability of further treatment and prognosis. If no tubercle bacilli can be found in the sputum the prognosis in children is better than if they are present. But the subjoined table of after-history results shows how nearly the course of cases with T.B. in the fæces tallies with those in whom T.B. are present in the sputum. The results in the two classes run parallel, and thus demonstrate that if no sputum is obtainable it is necessary to examine the fæces in order to be able to form a just opinion as to the prognosis.

| Cases. | Dead. | Worse. | Stationary. | Improving. | Quiescent. |
|---|---|---|---|---|---|
| 27 with T.B. in fæces but no sputum. | 2<br>(7 4 %) | 10<br>(37 %) | 5<br>(18·6 %) | 8<br>(29·6 %) | 2<br>(7·4 %) |
| 50 with T.B. in sputum and fæces. | 4<br>(8 %) | 18<br>(36 %) | 9<br>(18 %) | 16<br>(32 %) | 3<br>(6 %) |

### *Summary.*

On review of the evidence submitted it would appear: 1. That non-pathogenic acid-fast and alcohol-fast bacilli are not found in human fæces, and that tubercle bacilli are not found in the fæces of healthy individuals. 2. Tubercle bacilli, if present in the sputum, can be demonstrated in the fæces in 100 per cent. of cases. 3. In no case in which the sputum on repeated examination was negative for tubercle bacilli were these bacilli found in the fæces. 4. In children suffering from pulmonary tuberculosis tubercle bacilli can frequently be found in the fæces when no sputum can be obtained for examination. 5. The presence of tubercle bacilli in the fæces is not necessarily evidence of an intestinal lesion. 6. In children, who so frequently swallow their sputum, the examination of the fæces for T.B. can be more generally applied than the sputum examination, and yields a higher percentage of positive results. 7. It is in consequence of definite value in diagnosis and prognosis.

The writer feels that a method which, though very little more intricate than the routine one for examination of sputum for T.B., increases the certainty of diagnosis by at least 9 per cent. is worthy of an extended trial, especially with regard to children.

# THE TREATMENT OF RECENT "POTT'S FRACTURE."

BY C. M. GREENSLADE, M.B. N.Z., F.R.C.S. ENG.,
ASSISTANT SURGICAL OFFICER, ROYAL NORTHERN HOSPITAL;
ASSISTANT SUPERINTENDENT, PADDINGTON INFIRMARY.

FOR the purposes of this article I am including under the title of "Pott's fracture" any fracture in the neighbourhood of the ankle-joint, where there is either backward or outward displacement of the foot, or both together. This is a subject to which much thought has been given, on which much labour has been spent, and about which, to judge by the literature, opinions differ materially. Unfortunately, the results of treatment in the past have, on the whole, been unsatisfactory. The method to be described is simple. In my hands it has been uniformly successful.

### *Diagnosis.*

As in many of the patients the region of the ankle is greatly swollen, recourse should be had to X rays as soon as possible to confirm the clinical findings. Should the displacement be obvious, no time must be wasted if a skiagram cannot be obtained immediately. The earlier the nature of the injury is accurately diagnosed and treated the better; reduction is easy when the soft parts are not fixed by adhesions; any pressure of bone ends on skin, blood-vessels, or nerves is relieved; the muscles have not contracted down and shortened the limb, nor has the blood and lymph exudate become organised. Other things being equal, the earlier the fragments are replaced the sooner will the patient be fit to resume his normal mode of life. Radiograms should be taken from at least two aspects, antero-posteriorly and laterally; occasionally a stereoscopic view may be valuable.

### *The Anæsthetic.*

To my mind spinal analgesia is the ideal method of rendering the manipulations painless; at the same time it produces absolute relaxation of the muscles; however, those who do not care to employ it will secure satisfactory results, in the majority of cases, with any form of general anæsthesia. Occasionally, indeed, an anæsthetic is not required; merely putting the leg up in the manner to be described will suffice. Inhalation anæsthesia has several disadvantages; the struggling which often occurs during the process of induction may increase the displacement and a simple fracture may be converted into a compound one. The anæsthetic has to be pushed to produce the same degree of relaxation as is obtained with a small dose of stovaine intrathecally. During the period of recovery a good result may be nullified by the movements of the patient. I find the only contra-indications to the use of spinal analgesia in the treatment of lower limb fractures are extreme youth, certain nervous disorders, and the desire of the patient to be "put to sleep." In the case of an adult, 30 minims of nepenthe by mouth 20 minutes before the operation helps to allay any anxiety that may be felt by a nervous subject. The solution used is 5 per cent. stovaine with glucose; 1 c.cm. of this contains 6 cg. of stovaine, an ordinary dose; however, ½ c.cm. gives adequate relaxation for manipulations around the ankle. Owing to the small amount used, the injection should be made just to that side of the mid-line corresponding to the side of the fracture. When the needle has been withdrawn, the patient is either left lying on the injured side for three minutes, or, if he has been sitting up, he is laid on his back with a sandbag under the buttock of the sound limb. This serves to localise the effect of the stovaine.

### *The Manipulations.*

About ten minutes after the injection the limb is thoroughly cleaned; the parts to be grasped by the surgeon are well powdered. Stockinet, sufficient to cover the foot and the lower three-quarters of the leg, is passed over the foot so as to leave the ankle exposed. A few vertical strips of adhesive strapping attach the upper end of the stockinet to the leg. The strapping must not cross the tibial crest owing to the risk of cutting through the skin here. The surgeon stands to the inner side of the affected limb. Where the injury is on the left side, he grasps with his left hand the inner surface of the leg immediately above the fracture. He takes the heel in the palm of his right hand, the fingers of this hand extending around the outer border of the foot on to the dorsum. The reduction is effected by pushing the leg downwards and outwards with the left hand, and pulling the foot upwards and inwards with the right. Occasionally traction is required, but usually the reduction is carried out by the one movement described. Should there be difficulty in overcoming the backward displacement, the patient is brought down the bed so that the foot projects beyond the end. A loop of towelling is then placed over the lower part of the leg. The heel is supported by both hands. The surgeon places his foot in the loop. By pressing downwards with his foot and at the same time lifting upwards with his hands, the backward displacement is corrected. The fewer the movements made to get the alignment, the less will be the damage to the soft parts, and the sooner the return to normal. The stockinet is pulled down over the foot and fixed to the upper bar of the cradle in such a way as to produce the maximum degree of dorsiflexion at the ankle. The leg is bandaged from below upwards over the stockinet and strapping. The ankle is palpated through the stockinet to make sure the desired position is maintained. If there is a blister or a wound the stockinet is cut away over it to permit the application of dressings. A loop of bandage is passed around the ankle and fixed to the outer and lowest bar of the Salter's cradle; another bandage is looped around the foot at the level of the metatarsal heads and tied to the upmost bar on the inner side. These bandages are prevented from slipping by fixing them with adhesive strapping. This arrangement helps to maintain the inversion of the foot. The weight of the leg prevents the backward displacement from recurring. The cradle is firmly fixed to the bed by bandages. For those patients with epilepsy or delirium tremens, it is advisable to apply a light removable plaster-of-Paris case around the stockinet; the limb is left suspended as usual. In very restless patients the limb may be absolutely immobilised by fixing it to the sides of the cradle with several loops of plaster-of-Paris bandage. The ankle may now be screened, and any readjustment made before the effects of the stovaine have worn off. I have rarely found this necessary; two skiagrams are taken later at a convenient time to record the fact that the correct alignment has been obtained.

### *After-treatment.*

The bandage around the leg is removed daily, and effleurage carried out through the stockinet, thereby encouraging early absorption of the effusion. All parts of the limb can satisfactorily be massaged without the risk of the masseur displacing the fragments. The other bandages are adjusted as they become loose. As soon as the major portion of the swelling has subsided, I adopt one of two methods of ambulatory treatment. My customary practice was to enclose the foot and leg in a light removable plaster case. The patient was then allowed to get about with the aid of crutches. The alternative method, which I at present am trying out, is to apply a plaster of the Delbet type (well described in "Minor Surgery and Bandaging" by Gwynne Williams) and permit the patient to walk on the foot at once. Personally I think the former method, except in perhaps the hands of "Delbet" enthusiasts, will give more general satisfaction. At the end of three weeks, or a little longer if the fracture has been a bad one, the patient gradually puts his weight on the plaster. As progress is made, so are the crutches replaced by sticks, and the sticks used less and less. From five to eight weeks from the date of fracture he is fitted with a boot, the inner edge of which is raised from a quarter to half an inch. The upper of the boot may with advantage be strengthened on the inner side so that, when laced, it prevents any tendency to inward displacement.

### *Results.*

I have now treated more than 30 successive cases with outward and backward displacement of the foot by this method, with uniformly good results. In only one has a fracture set in this way required any further manipulation. This patient, a man of 71 years, suffering also from delirium tremens, was so restless that his limb had to be reset and secured in a plaster case.

The advantages claimed for this method of treatment are: (1) The patient does not lose consciousness. (2) A minimum dose of stovaine is used. (3) There is no risk of pressure sores. (4) Absence of discomfort after the stockinet has been applied. (5) Very small chance of recurrence of displacement once reduction has been effected. (6) Greater freedom of movement at the ankle-joint. (7) Ability to walk earlier.

I have to thank Dr. W. G. Bendle, medical superintendent of the Paddington Infirmary, for permission to treat these cases and to publish the results.

PS.—Since writing the above article I have read the report in THE LANCET (Jan. 2nd and 9th, 1926) of the discussion in Manchester under the auspices of the British Orthopædic Association, on the treatment of this type of fracture. More than ever do I feel that the stockinet method, being so simple, and, with me, so satisfactory, should be given an extended trial. As a comment on the discussion, may I say that I feel sure it is a mistake to immobilise these fractures for any length of time; in fact, since using the modified Delbet method, I am certain that the sooner the patient can be made to walk on the injured limb, the sooner will he recover. The great disadvantages of immobilisation of the leg are that the muscles become atrophied even with daily massage, the patient imagines his injury is worse than it really is, loses confidence in his ability to walk, and has to be re-educated in the lost art. It was while attempting to maintain the fragments in position in a difficult backward displacement of the foot that the above method was evolved; however, some of the results quoted in the discussion must have been due, in my opinion, to the fact that inexperienced residents were treating the cases. The mismanagement of this type of fracture provides a strong argument in favour of Sir Robert Jones's plea for a special fracture service attached to each large hospital.

ROCKEFELLER FOUNDATION GIFT TO NORWAY.—The Foundation has offered the Norwegian Government a sum not exceeding 1,065,000 kroner for the completion of the work on the projected new Government institute for serum and vaccine research. The offer has been thankfully accepted

# A CASE OF HERNIA OF THE STOMACH AND TRANSVERSE COLON THROUGH THE DIAPHRAGM.

By E. CHITTENDEN BRIDGES, M.D. Durh.,
AND
J. FAWCETT, M.D., F.R.C.P. Lond.

*With a Note on the X Ray Examination by* Mr. Lindsay Locke *and a Note on the Operation by* Mr. T. P. Dunhill.

The condition about to be described is one of considerable rarity and interest and is therefore worthy of record.

Mrs. E. D., aged 60, began to have pain in the front of the chest accompanied by flatulence and a feeling of oppression when she was about 40 years old. For the last seven years she had suffered from sudden and severe attacks of abdominal pain of obscure origin. The pain was situated mainly in the left hypochondriac region radiating over the lower costal margin towards the mid-line. It lasted generally for about six or seven hours and terminated by an attack of vomiting. For the past two or three years the patient had not been free from severe attacks for a longer interval than six weeks, and between these she had suffered from slighter seizures. The attacks were quite irregular in onset, occurring at any time of day or night, but in the intervals there was no pain. In 1921 hæmatemesis first occurred, and again in 1922. On May 10th, 1924, a very severe attack of pain took place accompanied by frequent vomiting which lasted for 48 hours; after the first 12 hours the vomit contained clots of blood and subsequently "coffee grounds."

The patient stated that she had been constipated all her life. From the age of 9 to 20 years she had been subject to attacks of headache and vomiting; but otherwise there was nothing in her past medical history which had any obvious bearing on her condition.

On *physical examination* no gross lesion was discovered. The only abnormal physical signs were that over the left side of the chest behind and below the angle of the scapula there was impairment of resonance on percussion and the respiratory murmur was deficient.

The sudden and severe paroxysms of abdominal pain and vomiting, accompanied on three occasions by hæmatemesis, were quite unlike those due to the usual causes of pain in the region referred to. The attacks at once suggested to our minds the likelihood of a temporary strangulation—a kink of some part of the stomach or upper portion of the small intestine in, for example, a retroperitoneal pouch. In view of the increasing severity and frequency of the attacks it was decided that an exploratory operation was necessary, but before proceeding further it was decided to advise the patient to have an X ray examination of the stomach and alimentary canal, after administration of a barium meal, with the object of more accurately establishing the diagnosis.

### *Note by* Mr. Lindsay Locke.

"The abnormal conditions found at the X ray examination were:—

"The displacement of the heart to the right. This appeared to be due to something causing a shadow which encroached on the base of the left lung. The fact that the upper domed limit of this shadow moved on respiration synchronously with the right diaphragm would indicate that it was not inflammatory—e.g., due to pleurisy—and also that the left diaphragm was still able to contract.

"The stomach was practically inverted in position, and what should have been the lowest part of the greater curvature in its normal position now came to lie on a level with the third rib and formed the highest part of the dome. The pyloric end of the stomach overlay the cardiac orifice. The line of the left diaphragm was not visible. The transverse colon was looped up to the highest point of the stomach and its afferent and efferent limbs lay close together, suggesting that they were passing through a hole.

"The differential X ray diagnosis lay between hernia of part of the stomach and colon through the diaphragm and an ulcer causing distortion by cicatricial contractions, but this latter condition did not explain the high position of the stomach, so we were left with diaphragmatic hernia as the only explanation."

### *Note by* Mr. T. P. Dunhill.

"When the patient was first seen by me the X ray examination had already been made and it was known that the position of the stomach and part of the transverse colon was not normal. It is probable, in the light of the patient's history, the operation findings, and Mr. J. B. Hume's researches, that this malposition was congenital—indigestion had been present for 20 years—but in recent years the discomfort had become very troublesome, and attacks of pain and vomiting had occurred with increasing frequency and severity. There had been considerable loss of weight. The onset of hæmatemesis added another important sign; this might have been due to ulceration—innocent or malignant—but was more likely to be due to partial strangulation—kinking of the stomach across the edge of the diaphragmatic opening—the pressure being first manifested on the soft-walled veins. The symptoms, the signs, and the X ray evidence were such as to make exploration imperative. The operation was planned so that a thoracic and an abdominal incision could be joined if found necessary or advisable, the abdominal incision to be made first for purposes of exploration, so that the time that the thoracic cavity would need to be kept open should be reduced to the minimum.

"*Operation.*—On July 22nd, 1924, under intratracheal gas and oxygen with a little ether (Dr. I. W. Magill), Dr. Chittenden Bridges and Mr. Geoffrey Keynes assisting, the abdomen was opened by a left paramedian incision. On lifting the edges of the incision neither stomach, great omentum, nor left lobe of the liver could be seen. A loop of transverse colon was seen disappearing through the left dome of the diaphragm. This loop, together with the great omentum, could be withdrawn by gentle traction without difficulty from the aperture in the diaphragm. Further traction brought into view the greater curvature and then the whole stomach. There were no adhesions. A hand as far as the wrist could be passed through the opening into the thorax, and the heart, surrounded by its pericardium, palpated. With this hand in the thoracic cavity it was easy, by bimanual palpation, to decide on the right rib to remove at the later stage. The stomach readily slipped back into the thoracic cavity, which had evidently become its home. It was obvious that the left lobe of the liver was rudimentary. The investigation being completed, the abdomen was temporarily closed by three through-and-through sutures, in order to protect it, while the thorax was being opened. An incision about 8 in. long was made over the eighth rib—a dependent breast having to be well drawn up—about 7 in. or 8 in. of this rib removed, and the thorax opened. By means of a rib-spreader excellent access was obtained. The dome of the hernial sac covered with pleura was seen and the pleura incised. It stripped off easily from the peritoneum which constituted the sac. This was then incised and its glistening inner surface found to be continuous with the peritoneal cavity.

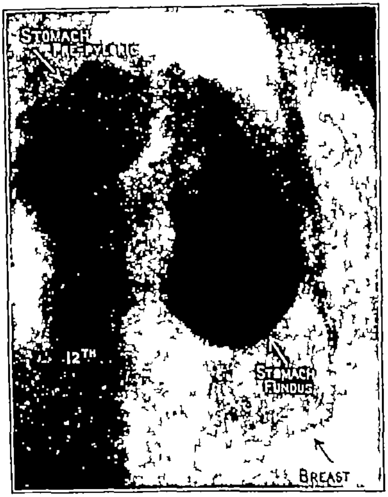
"The left margin of the defect in the diaphragm was well felt and seen. On the right side the margin was not felt and seemed to be lost in the diaphragmatic aspect of the pericardium. The three sutures which had temporarily closed the abdominal incision were removed and the stomach gradually drawn down again into the abdomen by my assistant. It appeared from this aspect that the cardia was just above the level of the diaphragm, as though the condition were congenital and the œsophagus rather shortened. As there was not a good free right margin to the defect the left margin was sutured to the base of the pericardium and to the tissues surrounding the œsophag this being done from the thoracic aspect. In this way defect was well closed, but at a rather higher level t normal. It did not make a normal diaphragm, but it m a barrier against the entry of the abdominal viscera i the thorax. The chest wall was then carefully sutured.

"From the abdominal incision three catgut sutures w passed through the sero-muscular coats of the anter surface of the stomach, and two others through the me colon at a point which corresponded to the apex of the lo of colon which had become accustomed to dwell in the thora Each of these sutures was passed through the pariet peritoneum at the appropriate spot and tied, thus giving t stomach and colon sufficient anchorage to maintain the organs in their new position until the repaired diaphrag became organised. The abdominal incision was then close in the usual manner."

### *Discussion.*

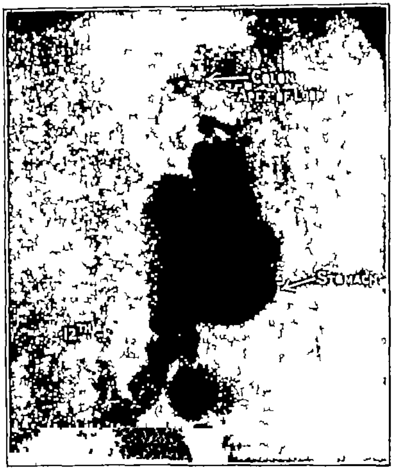
As confirmed by operation the case proved to b one of considerable rarity, due to a congenital defec

Fig 1



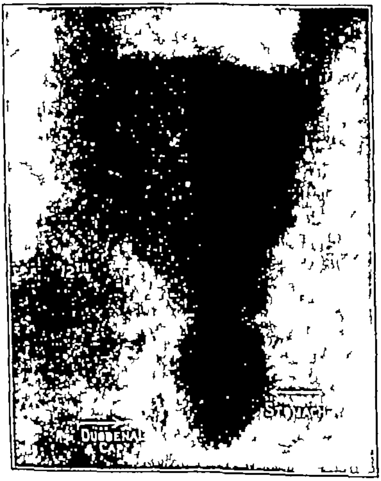
Before operation The pyloric end of the stomach reaches the third costal cartilage.

Fig 2



Before operation Loop of colon high in the hernial sac.

Fig 3



Three months after operation Axis of stomach lies normally

Hernia through the left dome of the diaphragm The liver has been removed. (After J B Hume, *Brit. Jour of Surg* October 1922.)

of the diaphragm, the hernia, as in most cases, entering the left pleural cavity, and consisting of the stomach and a portion of the colon; this subject has been well discussed by Mr. J. B. Hume.[1] The physical signs over the lower part of the left side of the thorax posteriorly, which were detected in a quiescent period after an acute attack, were no doubt the result of the defect in the diaphragm, which interfered with the normal respiratory movement of that side of the chest. Usually the thoracic signs are almost identical with those of pneumothorax in the lower part of the chest giving rise to a tympanitic note on percussion, fixation of the chest wall, displacement of the heart, with absent respiratory murmur and voice sounds. It would have been of interest to know if like signs existed during an acute attack; but even if they had been present the prominent abdominal symptoms of severe colic and vomiting would have made it clear that the thoracic signs were of secondary importance.

*X Ray Examination Three Months Later.*—This showed the left diaphragm to be extremely high, but the stomach is shown with its fundus and pylorus in the right relationship. Barium passed into the colon, and this organ did not enter into the thoracic cavity.

*Eighteen Months after Operation.*—The patient has increased in weight by 2 st. She has lost all symptoms of dyspepsia and expresses herself as never having been so well before.

# A NEW METHOD OF PHYSICAL EXAMINATION (ECTOSCOPY).

By DR. EDUARD WEISZ,
PISTYAN, CZECHO-SLOVAKIA.

WITH the aid of ectoscopy a diagnosis of the following conditions becomes possible.

1. The lower limit of a pleural effusion can usually be easily ascertained, though this has not hitherto been demonstrable, even by radiography.
2. Even low down posteriorly one may be able by this method to localise small effusions in the pleural space, where hitherto it has been impossible to find them, and to verify them by exploratory puncture.
3. By means of ectoscopy it is possible to localise small encysted quantities of fluid or pus from burrowing abscesses in the tissues when this is impossible by other methods, so that the first puncture with a needle reaches the fluid.
4. In the domain of gastric and intestinal disorders it is often possible to differentiate between functional and organic disorders.
5. Any trace of peritoneal irritation can immediately be demonstrated by ectoscopy, its origin localised, and its progress to peritonitis or, in a favourable case, its retrogression, may be followed ectoscopically with the naked eye.
6. In gynæcology acute inflammatory affections of the appendages can usually be recognised at the first glance and differentiated from all other pelvic conditions. In a case of ectopic gestation the progress and position of the rupture may be recognised with the naked eye.
7. The ectoscopic method can also be used in neurology, as, for example, in the diagnosis of the obscure origin of masked or abortive hemiplegic affections—sometimes many years after a hemiplegia has healed evidence of the occurrence may thus still be forthcoming.

All these observations may be made with the naked eye without touching the patient.

Of all the various ectoscopic phenomena to be observed on the thorax, abdomen, and back by applying the appropriate technique, only the "speech phenomenon" will be described here, as this has been worked out most fully and appears to be the most important. Just as the face shows the movements of expression so also may various speech movements be observed on the trunk; the "thoracic or intercostal speech phenomenon," the "abdominal speech phenomenon," and the "lumbar speech phenomenon." Technically it is important to note that the speech movements (speech phenomena) can only be well seen at the beginning of phonation. The patient should, therefore, be instructed only to enunciate single words or syllables very slowly—e.g., counting up to ten in the intervals. Up to a point an increased effort in the enunciation increases the speech phenomenon, but if the effort is excessive, optimum results are not obtained. As the speech phenomena are readily altered by alterations in the attitude and position of the patient it is important, when comparing the left side of the body with the right, to ascertain that the essential symmetry of the body is maintained by a correct attitude.

### *Principles of Ectoscopy.*

Of what, then, do these phenomena consist? In those parts of the thorax not covered by large masses of muscle or by the scapula—i.e., where the intercostal spaces are at least partly visible—the following may be observed. At the beginning of each effort of speech the intercostal furrows disappear and the intercostal wall not only rises to the level of the ribs but protrudes beyond. As the sound of the word of one syllable dies away again this intercostal protrusion also subsides to its original level. If one, then, after an interval instructs the patient to speak again, one can obtain a repetition of the intercostal protrusion as often as desired.

The intercostal speech phenomenon—i.e., the phonetic protrusion of the intercostal spaces—is due to the more or less complete closure of the glottis during phonation; as a result the air squeezed upwards by abdominal contraction cannot escape sufficiently rapidly by this route, so that, analogous to an explosion on a small scale, the excessive expiratory pressure forces the lung into the intercostal spaces and forces them outwards. The intercostal speech phenomenon can be best seen in the second and third intercostal spaces in the parasternal line, laterally in the lower axillary region, and posteriorly on the lower part of the thorax as far as the scapula line. In most patients the intercostal speech phenomenon is most obvious at the borders of the lungs. This is due to the fact that the intercostal protrusion produced by speech can only be effected by the outward pressure of the lung, and not by the more solid organs of the spleen and liver which lie below the diaphragm and are, on account of their firmer consistency, not sufficiently pliable to be readily forced into the intercostal space so as to cause them to protrude.

### *Diagnostic Value of Ectoscopy.*

Thus the speech phenomenon separates the solid organs of the liver and spleen from the lung, and is therefore useful in defining the level of the patient's diaphragm. How, then, does an effusion in the pleural space modify the speech phenomenon in the intercostal spaces? As the intercostal protrusion during speech seems to be a phenomenon depending on the compression of air, it might be supposed that the fluid of an effusion would, by its very nature, be unable similarly to follow all the speech movements of the thorax. In effect, however, a pleural exudate also shows the speech phenomena well; the impulses and movements are readily transmitted to a fluid pleural effusion, and the waves thus produced become visible in the intercostal spaces which are protruded by the impact of these waves just as they are by the "phonetically" compressed air in the lungs. As, however, as already mentioned, the liver and spleen cannot take part in these "phonetic" protrusions, the lower limit of an effusion may readily be separated ectoscopically from the upper margin of the spleen and liver, which has not been possible by the methods of physical examination hitherto available.

Thus the area mapped out by the radiographic shadow and by dullness on percussion is divided into two separate parts by the speech phenomenon. In the upper part the intercostal spaces move during speech as they do over the lung; this, therefore, corresponds to the fluid effusion, while the lower remains stationary during speech and therefore contains liver and spleen. If a line be drawn across the area of dullness between that portion which moves during speech and that which does not, a needle will draw fluid at any point above the line, but puncture below will give a negative result. By this means it is possible to isolate small quantities of fluid posteriorly from a large area of dullness on percussion.

---

[1] Hume, J. B.: Brit. Jour. Surg., vol. x., No. 38.

A very important and extraordinarily interesting *field for the application of the ectoscopic method* is in the diagnosis of encysted fluid or a hidden abscess situated in the middle of a mass of dense tissue, the fluid nature of whose contents can be demonstrated neither by X rays nor by percussion. The following case is an example:—

A few years ago a young woman consulted me with a history that she had been to numerous doctors, had been X rayed several times at two different clinics, that an exploratory needle had on several occasions been inserted below the shoulder-blade, but no diagnosis had been reached. On examination an area of dullness barely the size of a child's hand was found between the scapular and paravertebral lines. Though I had not much experience in such matters, *I did think of the possibility of an encysted effusion.* I instructed the patient to repeat the word "kitt" at slow intervals, but the area of dullness remained unaffected; it did not move. Apparently it consisted of solid tissue, a tumour, an indurated mass of some sort. At length I noticed that in the centre of the quiescent area a small spot less than a finger-nail in diameter moved a barely visible amount during speech. If anywhere, therefore, a needle should draw fluid at this point. Superficial puncture produced no result, but a second puncture at the same spot resulted in several drops of pus, and a subsequent puncture with a longer and stronger needle produced *half a syringeful of pus.* At this point a surgeon was called into consultation at the clinic, and *spondylitis (? spinal caries)* with burrowing abscess diagnosed. The treatment consisted of a plaster jacket and subsequently a surgical corset.

In the *pathology of the abdomen and pelvis* the abdominal and lumbar speech phenomena show as follows. *If one watches the back or abdomen* of a person speaking one sees all sorts of movements, partly active and partly passive, in the abdominal and lumbar body wall with each effort of speech. If there is any painful or acutely inflammatory process present within the abdomen, especially one associated with traces of peritoneal irritation, the speech movements are found to be entirely absent as compared with the other unaffected areas. The rest of the abdomen speaks, the affected (diseased) area is silent. *Automatic* reflexes here ensure that, during speech, the areas which are diseased and particularly sensitive to mechanical pressure and strain shall not be affected by the *speech movements. The diseased* abdominal organs must be kept at rest at all costs, and reflex muscular inhibitions during speech help to effect this. One is reminded of the absence of movement of the "muscles on guard" in cases of appendicular irritability, in which the reflex muscular inhibitions of the abdominal wall are able to protect the focus of disease from all mechanical irritation. As a counterpart to this *défense externe* the speech block may be described as a *défense interne phonatorique.* In comparison with the former the latter is far more sensitive and extraordinarily delicate.

To cite only a few illustrative examples from my collection of cases:—

Perforation of a gastric carcinoma seen a few hours after rupture. The left upper quadrant of the abdomen does not move during speech. The perforation is therefore probably situated here. *Tuberculous peritonitis:* A quarter of the abdomen is at rest, three-quarters move with speech. *Apparently, therefore,* three-quarters of the abdomen are unaffected. *Fistulous abdominal tuberculosis:* Three quadrants of the abdomen are silent, only one quadrant speaks. *Gastric ulcer:* The left half of the gastric area is at rest. *Duodenal ulcer:* The right portion is silent. *Cholecystitis:* Right upper portion of the abdomen is "phonetically" inhibited.

An incipient cholecystitis is also associated with an absence of speech movements in the right upper portion of the abdomen, which spreads with the progress of the disease, and is again replaced by normal speech movements as the disease disappears. The gynæcologist has the advantage that he can palpate a diseased area fairly thoroughly before opening the abdomen, and can thus verify the ectoscopic findings as it were by an "autopsy in vivo." My own limited experience in this field has been extensively confirmed by Weinzierl at Prof. Wagner's Clinic in Prague in his work covering some hundreds of cases. In every acute inflammation of the uterine appendages a corresponding inhibition or absence of the speech movements over the diseased focus is found. In all other *pelvic lesions the speech movements remain normal.* Thus it is possible to follow ectoscopically the development of an (abdominal) peritonitis from a pelvic peritonitis, and the progress from a partial to a general involvement of the peritoneum.

### *Applications of Ectoscopy to Neurology.*

*Next we will deal briefly with the applications of* ectoscopy to neurology. Since speech movements and reflexes are connected there must also be some *connexion between speech movements and the diseases* of the nervous system. This connexion is most obvious in the unilateral affection of a typical hemiplegia. If we watch the speech movements of the abdomen and back in one of these patients with unilateral paralysis we find—as is to be expected—that during phonation the unaffected half of the back and abdomen moves normally—i.e., the sound half speaks, while the paralysed half does not move; it remains silent. By this sensitive method one may the more readily prove the presence of a mild hemiplegic attack which *has run its course rapidly and unnoticed.* Similarly, one may demonstrate after many years by ectoscopic *differences in the abdomen during speech* the presence of an old hemiplegia which has apparently been completely cured. Naturally, the method fails occasionally and these failures have to be explained and elucidated; as exceptions they help to prove the rule.[1]

### *Technique.*

Finally we will give a short description of the technique. On the abdomen and back the speech phenomena are generally so coarse as to be obvious to the observer without any further preparation. The position and posture of the patient have some *effect. For example,* when the patient is erect certain portions of the abdominal and dorsal musculature assume their normal tone, so that the movements of the abdominal wall usually appear less vigorous than *when, as in the horizontal posture,* the muscles are relaxed. It is therefore advisable, if possible, to examine the patient erect as well as recumbent.

*As it is hardly possible without prolonged practice* to observe the speech movements of the whole abdomen or back at once, so precisely as to obtain a mental impression of all the fine movements of each portion, it is advisable to examine the back or abdomen in small segments, one at a time, while the remainder of the back and abdomen is covered. The abdomen should preferably be *divided into four* quadrants by an imaginary cross having its centre at the umbilicus. According as to whether the upper *right and left portions* of the abdomen or the lower *right and left portions* are to be compared, the lower or upper half of the abdomen is covered with a towel. If the upper and lower *quadrants* of the same side are to be compared, the opposite half of the abdomen is covered. Similarly, the back may be divided up and covered.

Conditions in the thorax are not nearly so simple as in the abdomen. If the intercostal speech movements are to be examined one must proceed as follows. First of all, by placing the arms horizontally ("crucifixion attitude") the upper anterior intercostal spaces become more readily visible, and in them the *speech movements.* A useful position for examining the back is the "self-embracing" attitude. The fingers of the patient reach as far back as possible on the lateral thoracic wall. By this means the scapulæ, especially their lower portions, are displaced laterally as far as possible, and the medial borders of the scapulæ *take up an oblique attitude* instead of the normal vertical position. The inferior angle of the scapula is thus displaced several centimetres outwards and a larger area of the intercostal spaces *on the posterior* thoracic wall becomes accessible for observation of the speech movements. In order to examine the important lower axillary portion of the thorax it is best to instruct the patient to place his hand on his head, so that the whole lateral view may be unobstructed. In thin individuals no further manœuvres are generally required. If in the more obese there are no very obvious deep intercostal furrows various positions (stretching out, diagonal, &c.) should be tried in order to improve them. For example, when the back is examined, the patient should bend over forwards; when one side is examined, he should lean over to the opposite side. Sometimes a diagonal or oblique position between the two may be chosen. Excessive use of these positions is, however, not to be recommended, as the intercostal furrows thereby become too tense and the speech movements may be diminished rather than increased. In the excessively stout, in whom the adipose subcutaneous tissue hangs in massive folds, ectoscopy will generally have to be abandoned. But even here it is sometimes possible with the aid of both hands to draw thick folds of skin, as also the breasts of women, away from the field of observation and at least obtain a view of traces of the furrows which may possibly show traces of movements.

---

[1] Further particulars appear in my book Diagnostik mit freiem Auge (Naked Eye Diagnosis), published by Urban and Schwarzenberg, Vienna and Berlin.

The word "kitt" has been found the most useful of the various types of syllables suitable for ectoscopy. The patient should be instructed to repeat this slowly at intervals of five to ten seconds.

# MEDICINAL INDUCTION OF LABOUR: ITS CLINICAL ASPECT.

BY K. VERNON BAILEY, *M.C.*, M.D.,
CH.B. MANCH.,
RESIDENT SURGICAL OFFICER, ST. MARY'S HOSPITALS, MANCHESTER.

SINCE the publication of A. C. Williamson's[1] paper on Induction of Labour by the Use of Castor Oil and Quinine, much interest has been taken by the staff of St. Mary's Hospitals in this particular treatment. During the last few years labour has been induced in a large number of cases by this method, or a slight modification of it. In consequence, the efficiency of quinine and castor oil combined in stimulating the uterus to contract has been well demonstrated, and the specific action of these drugs on the uterine muscle, which is discussed by Williamson, has been recognised.

The object of this paper, based on the observation of 78 cases, is an attempt to assign to this treatment its correct place in obstetrics. From its comparative harmlessness the method may be legitimately employed in almost any case where an early onset of labour is desired. There are, however, definite types of case in which its employment is specifically called for. It is the clinical aspect of this special treatment, therefore, with which I wish to deal, and the 78 cases dealt with in this paper were chosen from this point of view.

The drugs are administered in the following way. A dose of two ounces of castor oil is given, and one hour later half an ounce of a mixture containing quin. sulph., gr. x.; acid. sulph. dil., ♏x.; glycerine, ♏xx.; sp. chlor., ♏v., and water to the half-ounce. One hour after this a simple enema is administered. This is followed after two hours by another dose of the mixture, also three hours later and again after four hours. In the cases of this series, which were also treated with pituitrin, this was administered in ½ c.cm. doses half-hourly, and continued until 3 c.cm. had been given, the initial dose being used five hours after the last dose of quinine.

This method more nearly approximates to that described by Watson; 40 gr. of quinine are used in the course of treatment. If the patient complains of nausea or ringing in the ears the treatment is discontinued.

### *Indications.*

Cases are often met with in the late months of pregnancy in which an immediate or early commencement of labour would be beneficial to the patient. In a large percentage of these, however, active interference to induce labour may be deemed unwise, both from the point of view of the risks involved and also on account of the uncertainty of the type of the resulting labour. The cases in which delivery by Cæsarean section may possibly be necessary, but in which a trial of labour would furnish valuable information, are those to which I now specially refer. The risk of sepsis after Cæsarean section is increased by examination or interference per vaginam beforehand, and so attempts to induce labour by mechanical means greatly add to the gravity of the prognosis should delivery by Cæsarean section to procure a living child become eventually necessary.

The chief and definite indication, then, for the induction of labour by medicinal means is in cases presenting uncertainty as to the progress of labour and in which induction by mechanical means is contra-indicated owing to the possible necessity of delivery by Cæsarean section. From this point of view induction may be necessary in either (*a*) primigravidæ or (*b*) multiparæ.

(*a*) Under this category comes the primigravida, who exhibits some degree of minor pelvic contraction (diagonal conjugate 4 inches). The presentation and position of the child being normal, the fœtal head may, at the time of observation, be: (1) Mobile at the pelvic brim—possibly due to causes other than the pelvic contraction; (2) fixed at the pelvic brim, but exhibiting some very slight degree of "overlapping"; (3) fixed but high, its greatest diameter being above the plane of the pelvic brim.

All points of this borderline type of case are taken into consideration, and it is adjudged that delivery per vias naturales is a sound possibility. Immediate induction of labour is deemed necessary to increase the possibility of obtaining a living child. The period of pregnancy may vary from eight months to post-maturity; 38 cases of my series belong to this class.

A good example is Mrs. H. B., a primigravida and two weeks post-mature. The fœtal head was mobile above the brim. The pelvis appeared normal. After the quinine and castor oil treatment labour commenced and the fœtal head passed through the brim. Interference was resorted to owing to the passage of meconium by the child in utero. On examination it was found that the umbilical cord was coiled twice round the child's neck. Delivery was effected by version, the forceps tending to slip when applied.

Another case was that of Mrs. L. F., a primigravida with a flattened pelvis. The diagonal conjugate was 4 inches. There was slight overlapping of the child's head above the brim, but I judged that it might be soft enough to pass through after moulding had taken place. Labour was induced and delivery terminated by the natural forces.

(*b*) The multipara, who is included under this category, may or may not exhibit pelvic contraction, but usually presents a history of previous difficult labours, either from this cause or from the size of the children. Free mobility of the fœtal head above the pelvic brim may be present, but, of course, has not the same significance as in a primigravida; 49 cases are varying examples of this type.

Mrs. M. T. had had one previous delivery by craniotomy at term. The pelvis was slightly contracted. The diagonal conjugate was 4½ inches. When seen, the patient was one week post-mature by dates, and the fœtal head was freely mobile above the brim, but as she was somewhat obese, it was not possible to gain much information by approximating the child's head to the brim manually. Labour was induced medicinally and its progress closely watched. Natural delivery was effected.

In another case, that of Mrs. E. W., there had been a previous difficult delivery by forceps, resulting in the birth of a dead child. Here, again, the pelvis was slightly contracted. The diagonal conjugate was 4½ inches. She was admitted when one week premature. The child's head was then freely mobile above the brim. Labour was immediately induced, and delivery of an 8¼ lb. child effected by the natural forces.

---

[1] Williamson: Surg., Gyn., and Obst., 1922, vol. xxxiv.

In such cases one would hesitate to induce labour by mechanical means or to interfere per vaginam when the case presented such possibilities of difficult labour.

Apart from purely mechanical difficulties which may call for induction of labour by mechanical means, other types of case present themselves as eminently suited to this treatment; for example, cases of uterine inertia persisting beyond a reasonable time, especially if there is definite dilatation of the os, or the membranes have ruptured some hours previously. Four cases of my series are examples.

The third type of case, which is admirably suited to this treatment, is that comprising accidental hæmorrhage and marginal or lateral placenta prævia. In these cases medicinal induction of labour is attended with such success as largely to negative any mechanical method, which, besides, would greatly increase the risk of sepsis.

I have also been led to employ it in other types of cases in which the induction of labour might justifiably have been undertaken by mechanical means. In a number of these I have found that induction by bougies will almost invariably succeed at the first attempt if employed within 24 hours of the termination of the medicinal treatment. In these cases, therefore, I usually induce labour by bougies about 12 hours after the completion of the medicinal treatment if there are no signs of labour having commenced by then.

Cases of post-maturity react well to this treatment (25 cases). Induction of labour for severe albuminuria of pregnancy or threatened eclampsia is well carried out in this way (eight cases).

I therefore believe that although labour may fail to commence after this treatment alone, the specific action of the quinine on the uterine muscle is maintained to such a degree during the next 24 hours that added mechanical stimulation (by bougies) quickly brings about its regular contraction.

### *Effect on the Progress of Labour.*

Patients in labour differ so markedly, both physically and temperamentally, that it is difficult to ascertain how far a particular type of labour may be due to treatment and how far to the patient's own nervous control. A number of cases suggested a definite shortening of the first stage, but further results were so irregular as to negative a constant finding.

The most regular feature which labours, carried out under the influence of quinine, exhibit is the relative painlessness of the uterine contractions—a feature present in fully 70 per cent. of cases in greater or less degree. In some it is so marked as to approach a condition of painless uterine contraction, the uterus having often to be carefully watched in order to determine that labour is in progress. The mother in such cases believes that she is not yet in labour, and in this a danger lies, especially in that type of case which demands to be closely watched. In other ways the labour progresses along normal lines. It must be remembered, however, that the cases which receive this treatment hold prospective difficulties in the type of labour and are hence, of necessity, prolonged. The pulse and temperature show no variation from the normal type.

*Interference During Labour.*—There is nothing to indicate that delivery by the forceps has to be resorted to more often by the use of this method—rather the contrary. Considering the type of case under discussion, the number of forceps-deliveries—nine of the 78 cases—is comparatively small. These nine were effected by the low forceps operation.

### *The Additional Use of Pituitrin.*

Even if it fails to initiate uterine contractions, I believe that quinine, given as described, brings about a certain amount of tone or uniform contractility in the uterine muscle itself. Pituitrin, if given when the uterine muscle is in this condition—that is, immediately after the course of quinine—is not so liable to produce the irregular and spasmodic contraction which has been known to cause rupture of the lower uterine segment. The first 19 cases of this series were induced with the additional use of pituitrin and without any untoward occurrence. The percentage of successes by this means, however (68 4 per cent.), was not even so high as that obtained by the use of quinine and castor oil alone (72 7 per cent.), and I believe it to be unsound to employ pituitrin in the first stage of labour. The latter 55 cases of this series were conducted without its use.

Pituitrin may be of assistance with negligible danger in the induction of abortion, when this is inevitable, and the uterus does not exceed the size of a five months' pregnancy. Especially is it useful to complete an inevitable abortion at anything up to three and a half months, the uterus then being unable to accommodate the smaller hydrostatic bags. From this stage to five months abortion lends itself to induction by a hydrostatic bag with greater success immediately following a course of quinine and pituitrin, as do later labours to bougies immediately after the quinine course alone.

The danger, therefore, of the production of irregular and spasmodic uterine contractions by the administration of pituitrin is minimised by the quinine course immediately preceding it. It is this fact which, I believe, makes its use legitimate in the production of complete abortion at the dangerous stage up to three and a half months, or even up to five months, when conditions are not favourable to uterine rupture during labour In cases beyond this stage, however, pituitrin should never be used, as the production of anything but regular and uniform uterine contractions is both scientifically unsound and extremely dangerous, especially in the type of case which particularly lends itself to medicinal induction.

### *Conclusion.*

The chief point to which I would draw attention is that labour was successfully induced by purely medicinal means in 57 out of 78 cases, or 73 per cent. These are divided into a small group of the earlier cases in which pituitrin was also used, and a larger group of later cases in which quinine and castor oil were alone used. It is interesting to note that the percentage of successes in the later group is larger than in the earlier cases. It would appear that the additional use of pituitrin in no wise increases the possibility of success—a further contra-indication to its use.

This high percentage of successful inductions by medicinal means assigns to this method its place in obstetrics. This percentage of successful cases is higher than that reported by Williamson[1] (40 6 per cent.) and Muschallik[2] (58·6 per cent.), but not so high as Watson[3] claims with the additional use of pituitrin (90 per cent ). He, however, only obtained 20 0 per cent. of successes with the quinine and castor oil alone. But the number of my cases is far too small to attempt a comparison of statistics. It is chiefly made up of cases presenting possible difficulties with regard to the progress of labour, whether the pelvis be normal or otherwise. It is this clinical use of medicinal induction rather than the actual effects of the drugs themselves that I desire to emphasise. As far as the latter goes the work of Williamson and Watson places the matter beyond doubt.

Williamson states that the noteworthy points about his successful cases were: (1) the patient was due or past due by dates, (2) the head was fixed or beginning to engage; (3) the cervix was partially or completely obliterated and the minor os would admit a finger.

In the series here reported there were many successes with premature cases, and in others in which the fœtal head was mobile and the cervix closed and not drawn up. From a survey of these it would appear, therefore, that quinine is definitely able to act upon a closed cervix—a point which Williamson apparently considers doubtful.

In conclusion, therefore, I would wish to emphasise the fact that in cases where induction of labour is indicated but where methods involving interference per vaginam are contra-indicated, this treatment is definitely called for. Only in two of the series was Cæsarean section found necessary after labour induced by this means had been given a short trial, but without it how many would have been subjected to it, and in how many would the prognosis, after Cæsarean section, have become necessarily graver if mechanical attempts at induction of labour had previously been made?

# Clinical and Laboratory Notes.

## A CASE OF CORONARY EMBOLISM.

By Charles H. Miller, C.B.E., M.D. Camb., F.R.C.P. Lond.,

CONSULTING PHYSICIAN, LONDON HOSPITAL; ASSISTANT PHYSICIAN, ROYAL DEVON AND EXETER HOSPITAL.

A number of references have recently been made in The Lancet to the clinical syndrome of thrombosis of the coronary arteries. Embolism of the coronaries is rarer than thrombosis, and the following note is of a case that I believe to have been embolism.

### *The Case Described.*

On May 6th, 1925, a male patient, aged 55, underwent an operation for intestinal obstruction of a non-malignant nature. It was necessary to relieve the obstruction by temporary drainage of the cæcum. He was extremely ill for many weeks after the operation. On May 24th there were signs of consolidation at the right base and in the axilla. Later there were signs of fluid with displacement of the heart to the left. The fluid was deeply blood-stained and sterile. The pulmonary condition may have been infarction. He made good progress, and on Sept. 17th an operation was performed to close the cæcal fistula. The operation was only partly successful at first but eventually the opening into the intestine was shut off. He was comfortable and in good health until Oct. 1st.

On Oct. 2nd, at 3 A.M., he woke with a shout and a start. His head felt full, he had great pain across the chest, chiefly on the left side. The pain was described as tight and clutching. He became cold and clammy with a subnormal temperature. The cheeks were a dusky blue and he was a leaden grey about the mouth. The radial pulse was not palpable and it seemed as if he would die in a few minutes. This condition persisted with little change through the day. At 5 P.M. the pulse was just palpable at the wrist but was very rapid and irregular. The hands were cold and clammy and he was sweating profusely on the head and chest. There was still great pain in the left side of the chest. The mental state was clear but apprehensive.

On examining the chest I found the apex beat in the anterior axillary line 4¾ inches from the mid-line. The cardiac dullness extended to the right of the sternum 2 inches from the mid-line. On auscultation there was a confusion of unrecognisable faint sounds but a distinct friction was heard in the third and fourth left interspaces close to the sternum and outwards for an inch. At 6 P.M. he was a better colour. The cardiac dullness was smaller and there was a resemblance in the heart sounds to a triple rhythm. Some beats did not produce a pulse at the wrist. The friction was not heard. At 8 P.M. the radial pulse was palpable and regular and had the characteristics of pulsus alternans, which persisted until 1 A.M. on Oct. 3rd. During the night he slept, became a better colour, and the sweating became less. He was out of pain. During sleep the pulse was regular and 120. Oct. 3rd: He had a good day and was comfortable though tired. He slept a good deal. At 6 P.M. the cardiac dullness was bounded by the left border of the sternum and the apex beat was 4 inches from the mid-line. The heart sounds were faint but audible and friction was again heard then and on the morning of the 4th, when he looked very much as he did before the attack though the pulse was 110 to 120. The temperature was subnormal for several days. The pulse remained rapid for ten days and then came down by degrees to 80.

He is now quite well, and as the wound is healed he is taking up his ordinary life once more.

### *Comment.*

The points of interest are: (1) sudden onset; (2) nearness to death for several hours; (3) persistence of thoracic pain for many hours; (4) complete temporary destruction of the cardiac rhythm which passed through a phase of pulsus alternans before returning to a regular but rapid rhythm; (5) pericardial friction, which was audible on some occasions for three days. There was no breathlessness; the liver was not enlarged; the back of the chest was not examined.

It would seem likely that this was a case of embolism of a branch or the main channel of the descending division of the left coronary artery. Where did the embolic material come from? Was it from the left auricular appendix where thrombus had formed during his stay in bed? Or, bearing in mind that he probably had had previously a pulmonary embolus, may not an embolus from the abdominal wall have passed through a patent foramen ovale? I will not offer an answer to these questions, but am content to put on record a probable case of coronary embolism with recovery.

## A CASE OF PNEUMOCOCCAL PERITONITIS.

### RECOVERY WITHOUT OPERATION.

By P. O. Ellison, M.B., B.S. Lond.,

ASSISTANT PATHOLOGIST, ROYAL NORTHERN HOSPITAL;

H. Letheby Tidy, M.D. Oxf., F.R.C.P. Lond.,

PHYSICIAN, ROYAL NORTHERN HOSPITAL; ASSISTANT PHYSICIAN, ST. THOMAS'S HOSPITAL;

AND

L. G. Williams, M.R.C.S. Eng., L.R.C.P. Lond.,

HOUSE PHYSICIAN, ROYAL NORTHERN HOSPITAL.

The following case appears to be an example of pneumococcal peritonitis recovering without operation.

G. N., a girl, aged 11, was admitted to the Royal Northern Hospital on March 3rd, 1925. On the previous day she had complained of general abdominal pain, and had vomited several times; the bowels had been constipated.

*Previous Health.*—In March, 1923, she was admitted to this hospital complaining of cough and pain in the right side of the abdomen of three days' duration. On admission, at the base of the right lung there were crepitations and broncho-vesicular breath sounds. The temperature was 101° F., the pulse-rate 100, and the respiration-rate 30. Three days later no abnormal physical signs could be found in the chest. There was slight tenderness in the right iliac fossa. She was discharged after two weeks, apparently in perfect health. No definite diagnosis was made, but it was thought to be either subacute appendicitis or mild pneumonia.

*Present Attack.*—On the day of admission the pain in the abdomen was more severe than on the previous day and there was slight cough. The abdomen moved well and no rigidity, but a general tenderness was present, perhaps most marked in the right lower quadrant. No other abnormal physical signs. The temperature was 99°, the pulse-rate 100, and the respiration-rate 25. On March 4th she was seen by a surgeon, who did not consider that appendicitis was present, and suggested that the condition was due to the lungs. The same evening the patient had a rigor; the temperature rose suddenly to 103°, the pulse-rate to 130, and the respiration-rate to 38. On the 5th she was transferred to the medical wards. She was still complaining of abdominal pain and there was slight cough but no expectoration. The face was flushed and the eyes bright, the conjunctivæ slightly injected. There was no rash. The tonsils were not enlarged or inflamed. No abnormal physical signs were found in heart, lungs, or nervous system. The abdomen was moderately distended but not tense. On palpation there was no muscular rigidity, but a general doughy sensation. The tenderness appeared general. Liver and spleen were not palpable. Blood culture, agglutination for the enteric group, and a blood count were performed on the 5th. The blood cultures were sterile. Agglutination was negative to *B. typhosus* and *B. paratyphosus* A and B in dilutions of from 1 in 25 to 1 in 250. The blood count showed 10,000 leucocytes per c.mm. with 73 per cent. of polymorphonuclear neutrophils and 2 per cent. of eosinophils. The cough ceased in the course of a few days and did not recur, and no abnormal physical signs developed in the lungs. Throughout the illness there was no complaint of headache, and no rash, cyanosis, glandular enlargement, or diarrhœa, and while under observation no vomiting.

The bowels were usually open once or twice a day with the aid of aperients.

From this time for nearly six weeks the patient became steadily worse. Temperature remained between 100° and 103°, moving *irregularly; pulse between* 100 and 130; respiration-rate about 25. On March 11th a second blood count showed an increasing polymorphonuclear leucocytosis, absence of eosinophils, and the presence of anæmia. The red cells numbered 4,300,000 per c.mm., and the hæmoglobin was 75 per cent. The leucocytes were 20,000 per c.mm., with 83 per cent. of polymorphonuclear neutrophils, and no eosinophils were seen. By the 20th the patient was profoundly ill and wasting rapidly. At night she was delirious, but was clearer during the day. She complained continually of abdominal pain, and occasionally acute attacks occurred for which she was given injections of morphine several times. A few rigors occurred at night. The abdomen was extremely tender on palpation. No local masses or tumours could be felt. The tip of the spleen was just palpable. On the 25th a blood count showed a rapid increase in the anæmia, increase in the polymorphonuclear leucocytosis, and a complete absence of eosinophils. The red cells numbered 3,200,000 per c.mm., and the hæmoglobin was 55 per cent. The leucocytes were 21,000 per c.mm. with 81 per cent. of polymorphonuclear neutrophils, and no eosinophils. By the 30th the wasting had become extreme and delirium was practically continuous. She still complained of severe abdominal pain and resented palpation. The abdomen was full but not tense, and the doughy sensation remained. The spleen was somewhat larger. There was no sweating. She was losing ground rapidly and now appeared certain to die. No satisfactory diagnosis had been made, but some form of tuberculosis was considered probable. From March 30th to April 3rd she appeared to be holding her own, and the temperature and pulse were lower. From April 3rd to 11th an exacerbation of abdominal pain occurred. The temperature rose to 104° and the pulse to 130, and the condition again appeared hopeless.

On April 11th a definite improvement occurred, and continued afterwards without intermission. By the 20th she was definitely better, mentally clear, and commencing *to take food. The abdomen was still tender and the spleen* just palpable. By the 30th the abdominal tenderness was very slight and the spleen was not palpable. Her weight was 5 st. 8 lb. The temperature had fallen to between 98° and 99°, and the pulse to between 100 and 110. By May 5th she was practically convalescent, though some slight abdominal tenderness remained and the abdomen was still somewhat distended and doughy. A blood count showed an improvement in the anæmia, a return of eosinophils, and a fall in the polymorphonuclear leucocytes with an absolute increase of lymphocytes. The red cells were 4,000,000 per c.mm., and the hæmoglobin 65 per cent. The leucocytes were 12,000 per c.mm. with 46 per cent of polymorphonuclear neutrophils, 43 per cent. of lymphocytes, and 3 per cent. of eosinophils.

On May 13th an agglutination test against the pneumococcus was made with the following result.

| Serum. | 1 in 2. | 1 in 5. | 1 in 10. | 1 in 20 | Saline. | Type of Pn. |
|---|---|---|---|---|---|---|
| Patient | Trace | – | – | – | – | 1 |
| " | – | – | – | – | – | 2 |
| " | + + | + + | + + | + | – | 3 |
| Control A | – | – | – | – | – | 3 |
| " B | – | – | – | – | – | 3 |
| " C | – | – | – | – | – | 3 |

The patient's serum caused complete agglutination of type 3 pneumococcus at a dilution of 1 in 10, and agglutination without sedimentation at 1 in 20; type 1 was only slightly agglutinated at 1 in 2, and type 2 was not affected at any dilution. Three control sera were tried against the type 3 pneumococcus with negative results. In view of the low titres obtained in agglutination tests with pneumococci, the above result was regarded as positive for type 3 pneumococcus.

The patient's subsequent progress was an uninterrupted improvement. She was discharged from hospital on June 4th in satisfactory general condition. No abdominal tenderness remained, although the abdomen still appeared somewhat full. The weight had increased to 6 st. 12 lb.

### *Commentary.*

The diagnosis was in doubt throughout the acute period. In the earlier stages the most likely conditions appeared to be appendicitis, pneumonia, and enteric. Against appendicitis was the complete absence of any rigidity in the abdomen and of localisation of the tenderness. No abnormal physical signs were found in the lungs throughout the attack. As the illness continued it no longer suggested typhoid fever. As the condition advanced and wasting became marked we were inclined to accept the diagnosis of some form of generalised *tuberculosis,* though without being satisfied by this explanation.

Unfortunately it was not until May 12th that the possibility of pneumococcal peritonitis occurred to us. The agglutination test then showed a definite reaction with type 3 strain of pneumococcus, while various controls had no effect. We have been unable to find a record of a similar case in which agglutination reactions have been performed. The patient returned to hospital on June 28th for observation and then appeared to have recovered completely.

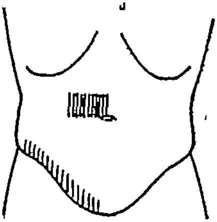
---

## HYPERÆSTHESIA IN DISEASE OF THE GALL-BLADDER.

By Zachary Cope, M.D., M.S. Lond.,
F.R.C.S. Eng.,
SENIOR SURGEON TO BOLINGBROKE HOSPITAL.

In some observations on cutaneous hyperæsthesia in acute abdominal disease published in The Lancet in 1924, I pointed *out that in gall-bladder disease* increased sensitiveness of the skin might be found either in the ninth segmental area or in the region just above Poupart's ligament on the right side of the body. At that time the comment was made: "It is quite conceivable that both the upper and the lower areas might be simultaneously involved in a case, but so far I have never seen such an occurrence." Since that time I have met with two cases which showed both areas of hyperæsthesia. Curiously enough, the first to show this interesting combination was a member of the medical profession.

Dr. X, aged 28, whom I saw in January, 1925, on account of severe pain in the right upper abdomen. He had recently had several such attacks, but the attack for which I saw him was more disabling than the others. There was tenderness and slight resistance in the right hypochondrium. On stroking the skin with a pin a very definite rectangular area of hyperæsthesia was found in the ninth segmental area above and to the right of the umbilicus, *whilst another* hypersensitive area was detected as a band about an inch and a half broad, stretching just above and along the whole length of the right Poupart's ligament. Diagnosis of cholecystitis with peritoneal irritation was confirmed at operation, when I removed a gall-bladder distended and in a state of subsiding inflammation. No gall-stones were present.



Areas of hyperæsthesia found in both cases described in the text.

The second case was seen at the Bolingbroke Hospital in August, 1925. A woman of middle age presented signs of inflammation in the right hypochondrium, and gave a history suggestive of biliary colic. She was slightly jaundiced. Examination showed two areas of hyperæsthesia almost exactly similar to those described above. Diagnosis of acute cholecystitis with gall-stones was confidently made and confirmed at operation. Six small gall-stones were found near the neck of the gall-bladder, which was in a state of subsiding inflammation.

In both of these cases the gall-bladder was removed and convalescence was uninterrupted.

Considering these two cases and others in which but one of the two areas were found to be involved, it appears reasonable to conclude that the simultaneous presence of these two areas of hyperæsthesia gives definite evidence of inflammation of the gall-bladder, accompanied by a certain amount of peritoneal irritation.

# Medical Societies.

## ROYAL SOCIETY OF MEDICINE.

### COMBINED MEETING OF THE SECTIONS OF MEDICINE AND COMPARATIVE MEDICINE.

A combined meeting of these Sections was held on Jan. 26th with Dr. Hugh Thursfield, the President of the Section of Medicine, in the chair, when a discussion took place on

### Hodgkin's Disease in Man and Animals.

Sir **Humphry Rolleston**, who opened the discussion on behalf of the Section of Medicine, said that the disease was variously known as Hodgkin's lymphogranuloma, lymphadenoma, and lymphogranulomatosis. In 1865 Cohnheim applied to a condition in which the enlarged lymphatic glands had the histological structure seen in leukæmia, but the blood did not, the term aleukæmic leukæmia. A better term for this was aleukæmic lymphadenosis. Sir Humphry Rolleston favoured the use of the term Hodgkin's lymphogranuloma, as suggested by Prof. H. M. Turnbull. According to the returns of the Registrar-General, the disease seemed to be becoming commoner, for in the last ten years the deaths from it had risen from 280 to 371. The cause of the disease was unknown, and the only means of exactly defining what was meant by the name was a description of its histological structure. In fact, the diagnosis in a given case could be made only on microscopical characters. The response to radiant and other treatments could not be regarded as diagnostically conclusive. He recalled the main histological appearances, as independently described at about the same date by Prof. F. W. Andrewes and Miss Dorothy Reed—namely, (1) a diffuse alteration of the structural architecture of the glands as a whole, which showed (2) a diminished number of lymphocytes, (3) endothelial hyperplasia, (4) so-called lymphadenoma cells, and (5) in some cases well-marked eosinophilia. Often in the early stages there existed a leucopænia; while when the disease was widespread there was commonly a polymorphonuclear leucocytosis. Biopsies could not be regarded as free of fallacy, as the excised gland might show nothing more than an indefinite lymphoid hyperplasia, due either to inflammation, or as a process which was compensatory for the destruction of other lymphatic glands.

#### *Nature of the Disease.*

Three main views as to the nature of the disease had been advanced: that it was a neoplasm, a transition stage between neoplasm and inflammatory formation, or—the idea favoured by the speaker—an infective granuloma. The virus had been believed by various workers to be the tubercle bacillus, a Gram-positive pleomorphic diphtheroid bacillus, and a spirochæte, but Sir Humphry Rolleston considered none of these had been firmly proved to be the cause. He thought there were several reasons for looking upon Hodgkin's disease as a neoplasm, the chief being that in its early stage it was localised to existing lymphadenoid tissues, while at a later stage it invaded other non-lymphoid tissues and became generalised after the manner of a sarcoma. Also, in the late stages the histological features were, or might be, those of sarcoma, so that Ewing applied to it the term "Hodgkin's sarcoma." It was very difficult to decide whether the lymphogranuloma became transformed in its course into Hodgkin's sarcoma, or whether the condition was sarcomatous from the start and became more virulent as the resistance of the patient was lowered. Possibly a gland which was originally merely chronically inflamed became malignant later.

It was usually considered that the cervical glands were the primary site of lymphadenoma, as these glands had been said to be affected in from 50 to 76 per cent. of cases, though it did not follow that the glands first found to be enlarged were those first attacked. Based on the observation of 14 cases, Symmers stated that primary enlargement started in the abdominal or in the abdominal and thoracic glands ten times more often than in the cervical, and Ewing confirmed this. This matter of the starting-point was important because of determining in what area irradiation should be applied. Curiously, Hodgkin's disease very rarely attacked the lymphoid tissue of the alimentary canal.

#### *Is the Disease Transmitted to Animals?*

There appeared to be a lack of satisfactory evidence that Hodgkin's disease had ever been transmitted to animals, but Bunting and Yates, after repeated injections of the diphtheroid bacillus they isolated from lymphadenomatous glands into five Macacus rhesus monkeys, found in the latter appearances like those of the early changes of Hodgkin's disease as seen in man; this was a somewhat ambiguous finding as Bunting stated that the early stage of that disease resembled inflammation. Hodgkin's disease had been said to occur in the so-called lower animals, but Sir Humphry Rolleston asked how far this statement was based on clinical evidence and how far on the revelations of the microscope. The few recorded cases that he had come across could more correctly be named lymphoma. There seemed no reason why Hodgkin's disease should not occur in animals, but more information was needed as to the microscopic appearance in supposed instances.

#### *Diagnosis.*

The greatest difficulty in the differential diagnosis of Hodgkin's disease was its clinical separation from the primary sarcomata of lymphoid tissue. In many cases there was no other means than by the microscopical examination of an excised gland. Cases of secondary malignant growth in the cervical and supraclavicular glands might imitate Hodgkin's disease when the primary growth in the mediastinum or œsophagus was latent and there had been no skiagram. There were three clinical forms of tuberculous adenitis which must be considered in the diagnosis from lymphadenoma; the first was common, the second very rare, and the third very exceptional. The first of these, tuberculous glands in the neck, often simulated early lymphadenoma, especially when the glands showed tuberculous large-celled hyperplasia without necrosis or caseation. Secondly, generalised tuberculous adenitis might be accompanied by relapsing fever such as had been described as accom- panying lymphadenoma. When this form of adenitis occurred it might be associated with visceral infection. The third condition, but little seen in this country, was an adenolipomatosis, in which fatty growth occurred around lymphatic glands that might be tuberculous.

#### *Lymphadenitis in Animals.*

Prof. **G. H. Wooldridge**, speaking as a veterinarian, said that Hodgkin's disease was occasionally diagnosed in the lower animals, but he was sometimes in doubt as to the true nature of the disease so described. He believed the condition was infective and that it was a lymphadenitis, the causal organism having a low degree of virulence, and the effect being produced on the lymphatic glands, at first slowly. It was not due to the tubercle bacillus. In the cases about which he felt no doubt the condition had become well advanced before he saw the animal. There had been a gradual onset, accompanied by a hacking cough, and the pharyngeal glands were swollen and slightly painful. Often the appetite was well maintained until the disease was advanced, though there was a distinct loss of general bodily condition. Sometimes there were fainting fits. A constant feature was an almost universal enlargement of the abdominal glands. But the results of histological examination were disappointing. The blood showed no appreciable alteration in the number or the types of the leucocytes present. Though the spleen was considerably enlarged, it was of normal consistence, while the enlarged lymphatic glands showed only lymphoid hyperplasia. Up to the present time he had been disappointed in the result of treatment; the disease had been fatal in adult dogs in his hands, but he had had some success with young dogs. Prolonged exertion and excitement should be avoided, and the food should consist of meat, eggs, and milk; and cod-liver oil, extract of malt, and syrup of hypophosphites should be given. He had no experience of X ray or radium treatment; very few owners would go to that expense. He spoke also of a somewhat similar condition in sheep, known as caseous lymphadenitis, due to a Gram-positive diphtheroid bacillus. Usually it was seen only in the course of meat inspection, not during life, and the joint might be on the table before the lesion was seen!

### *Clinical Features of Hodgkin's Disease.*

Dr. H. **MORLEY FLETCHER** spoke mainly on the clinical features of the disease, which he thought was most likely of infective origin. The frequent occurrence in these cases of periodic fever was difficult to account for except on the assumption of an infective agent, probably a spirochæte, and this was supported by its behaviour under the administration of arsenic. It had been suggested that the pyrexia was due to the absorption of products from the glands; and the possibility of associated tuberculosis should always be borne in mind. He had usually found in the condition a polymorphonuclear leucocytosis of 10,000 to 14,000. The careful recording of minimum temperatures revealed the same type of chart as that associated with the name Pel-Ebstein. The abdominal manifestation of Hodgkin's disease might be latent, hence great difficulty might be experienced in diagnosing it. The result of X ray and arsenical treatment he had found to be striking, but the enlargement of thoracic and abdominal glands was liable to recur in a short time. He had not received encouraging results from the use of antimony.

Mr. L. P. **PUGH** said Hodgkin's disease was only one of a group of conditions in animals which showed a more or less generalised incidence on the reticulo-endothelial system, all being likewise characterised by some enlargement of the lymph glands, the liver, and spleen. These conditions were probably fatal, therefore a gland was not removed for histological examination. He considered that the leukæmias were due to spirochætes, and that this might also be true of Hodgkin's disease.

### *Experimental Work.*

Prof. M. J. **STEWART** (Leeds) described the inoculation experiments which were done by Dr. J. F. Dobson and himself on monkeys, injecting material from a succulent gland in a proved case of human Hodgkin's disease. In the first series pieces of gland were injected into the spleen and mesenteric lymph glands; in the second series an emulsion of Hodgkin glands was injected intravenously. A result in the first series was a striking hyperplasia of the lymph glands and of the lymphoid follicles of the spleen; in the ileocolic angle there was a chronic abscess with giant cells round about it. He regarded this as a foreign body reaction. In another case he found a small nematode in the pus, and there the foreign body reaction was stimulated by the presence of that parasite. The net result, in regard to the production of Hodgkin's disease, was negative. The evidence in favour of Hodgkin's disease being a granulomatous formation was very strong, and he believed a considerable proportion of cases ended with a condition indistinguishable from malignant disease. He gave an analysis of the findings in 400 cases in which glands were sent to his department for examination, and from the figures emphasised the great difficulty of diagnosing Hodgkin's disease clinically.

Mr. W. **HORNER ANDREWS**, speaking as a veterinarian, said his contribution to the discussion must be on the negative side, as, taking the histological changes as the criterion, he was not aware of a single case of Hodgkin's disease in lower animals. The condition which had been usually so regarded was one in which there was a general enlargement of lymphatic glands, usually associated with splenic enlargement, but not any leukæmia, and in which no bacterial cause, such as tubercle, could be demonstrated.

## SECTION OF UROLOGY.

A MEETING of this Section was held on Jan. 28th, Mr. R. H. **JOCELYN SWAN**, the President, being in the chair, when Mr. **GIRLING BALL** opened an informal discussion on

### PYELOGRAPHY.

He said that he used a large record syringe with a fine-bored needle and a solution of sodium bromide, or at times sodium iodide. He showed pyelograms of three cases:—

1. A man from Penang, complaining of renal colic without other symptoms, who produced 11 radiograms taken in all parts of the world and showing no evidence of calculus. The pyelogram showed typical early hydronephrosis with calculus. After the fluid had drained out a round shadow was left which proved to be the outline of a pure uric acid calculus, some of the opaque material having remained attached to it.

2. A girl of 10, with a chronic pain in the loin which incapacitated her for work. X rays showed shadows which were said to be calcareous lymph glands. The pyelogram showed the typical distension of the calyces associated with stone. When the kidney was removed 20 calculi were found in it.

3. A case showing the symptoms of renal disease and hæmaturia, diagnosed as calculus. A stereoscopic pyelogram showed that the shadow lay in front of the kidney; it proved to be a large mass of calcareous glands in the mesentery.

Mr. T. E. **HAMMOND** pointed out that the solution injected was of very high concentration and 12 per cent. sodium iodide might produce a severe reaction in the kidney. Possibly this was an idiosyncrasy to the drug; in one such case he had seen 10 gr. of iodide given by the mouth thrice daily produce iodism in two days. On account of this danger the pelvis should be washed out as soon as possible. Patients might also complain of irritation of the bladder after it had been washed out with oxycyanide of mercury; possibly this was due to the formation of sodium mercury iodide and might be obviated by the use of sodium chloride instead of oxycyanide. He showed slides illustrating a case of acute abdominal pain with a large tumour on the left side of the abdomen but no tenderness or rigidity, diagnosed as perforated gastric ulcer. The pyelogram showed no filling defect but a kink in the ureter. A tentative diagnosis was made of torsion of the spleen. At operation a large tumour of the kidney was found, and three months later the patient was admitted to hospital for intestinal obstruction. The pain was possibly due to hæmorrhage into the tumour. Another case, a woman of 40, had had pain on the left side for five years. A catheter would not pass into the kidney, but fluid injected led to pain similar to that she complained of. Pyelography showed a kink in the ureter. Under anæsthesia the catheter passed into the pelvis and was left for 12 hours. Since then there had been no symptoms. In another case of renal colic of five years' standing with bleeding from the left ureter, a No. 8 catheter failed to pass an obstruction 8 cm. up; a No. 7 passed into the pelvis, and the picture showed a dilatation of the ureter above the pelvic brim. At operation an abnormal uterine artery was found compressing the ureter above the pelvic brim, and there was a small uric acid stone.

Mr. **ALBAN ANDREWS** showed pictures of three cases:—

1. A man of 32 with congenital cystic kidneys; he had had hæmaturia from the left kidney for a week and one or two similar attacks during the preceding six months. Both kidneys were palpable, but the left was larger and more irregular.

2. A youth of 20 who had had one attack of pain in the right loin four months before being seen. There were no other symptoms except occasional cloudiness of the urine, thirst, and attacks of flushing and swelling under the eyes. Tests of function were quite satisfactory on the left but poor on the right. At operation adhesions were found between the ureter and the lower pole of the kidney with kinking.

The PRESIDENT remarked that Mr. Andrews had come up against the usual difficulty—the diagnosis between polycystic kidney and malignant disease.

Sir JOHN THOMSON-WALKER said that it was necessary to be careful about diagnosing disease on elongated calyces, which might produce no symptoms at all.

Mr. GILBERT SCOTT pointed out how important interpretation was and how difficult it was to decide whether any abnormality seen in the pyelogram was a variety of the normal or a pathological condition. Slight variations such as a partly filled pelvis might be due to faulty technique. He found it useful when in doubt to imagine that it was his own kidney on which he was pronouncing judgment. Technique should be as simple as possible; the whole process should be completed within half an hour. The catheter should be passed in the room in which the photograph was taken and three plates should be exposed—one before the injection; one when the pelvis was full, taken at full inspiration; and the third while the kidney was emptying, at full expiration. The two latter gave an idea of whether the kidney was fixed or not. The third picture might give evidence of a stone which the second did not show. A shadow was more likely to be thrown around the stone by sodium bromide than by collargol. A lateral view failed when it was most wanted for localisation of shadows in the kidney region; a far better method of localisation was to take two pictures, one in full inspiration and one in full expiration, noting whether the shadow moved with the kidney in all directions. He showed a number of cases:—

1. Of double ureter and pelvis on both sides with a hypernephroma of the lower pole on one side, the lower pelvis not functioning at all.

2. A slide showing the opaque substance trickling through into the tubules; it caused no ill-effects; some kidneys took the stain very easily.

3. A pyelogram showing variations of normal (*a*) very slender calyces, and (*b*) a number of small calyces.

4. Early hydronephrosis, with no blunting of the calyces, which did not show till very late in the condition, but revealed itself by increased breadth of the calyces and increased size of the pelvis.

5. Elongated calyces in a case of hypernephroma of the upper pole.

6. A similar hypernephroma showing the lower calyces dilated while the upper had disappeared altogether.

7. A similar disappearance of the upper calyces in what proved to be a benign papilloma.

8. A large calcareous growth which was never diagnosed.

In the last four cases a real diagnosis was very difficult; the great thing was to realise that a pathological condition was present.

Sir JOHN THOMSON-WALKER pointed out certain characteristics of the normal pelvis. The catheter should pass into the upper calyx, otherwise it raised the roof of the pelvis, which usually meant a displaced or abnormal kidney. In the normal pyelogram it was not possible to tell exactly where the pelvis ended and the ureter began. There was a certain curve between the upper ureter, the lower pelvis, and the lower calyx; in the abnormal kidney this curve became diminished or angular in proportion to the dilatation or displacement.

Mr. SWIFT JOLY showed a series of slides:—

1. A case with indefinite shadow in the lower pole after nephropexy. There were no primary calyces; all were of the secondary type.

2. A doubtful shadow which proved to be a bifurcation of the ureter.

3. A patient who had had a nephrolithotomy and showed a repetition of the symptoms. X rays gave an indefinite shadow, but the pyelogram showed that this was in connexion with the colon, and it proved to be a mass of tuberculous glands.

4. A small stone in both ureters on the level of the lowe pole. The picture showed the ureter still dilated five month after operation.

5. A case of double ureter.

6. Three patients with hæmaturia, with very few localising signs, diagnosed by pyelography as hypernephromata.

7. A case of renal tumour with marked distortion of the ureter and dilatation of the lower calyx.

8. A ureter drawn out into a wide curve, possibly due to immobility of the kidney.

9. A huge embryoma.

10. The kidney of a doctor from West Africa, who had had a series of boils since last August with pus in the urine. His condition progressed almost to a septicæmia, and when examined he proved to have a large fixed kidney and an irregular temperature about 102° F. The pyelogram showed an abscess opening into the middle calyx with elongation of the upper calyx.

11. A case of polycystic disease in a boy of 15.

12. A tuberculous kidney.

13. Extreme rotation of a kidney with abnormal renal artery.

11. Rotation with an abnormal artery passing through the upper pole and producing symptoms which were relieved by division of the vessel.

15. Two cases three years after nephropexy, showing the kidney dropped again with kinking of ureter.

16. An oxygen pyelogram of hydronephrosis, which had been operated on as a mesenteric cyst.

17. A large hydronephrosis in one-half of a horse-shoe kidney which the pyelogram failed to diagnose.

18. A case suspected of being a horse-shoe kidney but shown by pyelogram to be two separate organs with the right one rotated and the seat of malignant new growth.

Mr. F. McG. LOUGHNANE said he had had a number of cases of mobile kidney with no marked symptoms save, occasionally, frequency of micturition or painful micturition, or slight right-sided abdominal pain. All had shown a definite hydronephrosis on pyelography. He showed slides of two such cases of pain in the right iliac fossa, one of which was taken four years after appendicectomy. Injection of sodium iodide in each case caused the characteristic pain. He also showed a slide of perirenal oxygen inflation, showing the right kidney swivelled round the spine, and another showing hydronephrosis 15 years after nephropexy.

Mr. H. C. GAGE said that sodium iodide not stronger than 7–10 per cent. gave a thin but very good picture. With a stronger concentration the technique must be changed and the tension raised to 70,000 or 80,000 volts to get the necessary penetration and show any umbilication of the ends of the calyces. Otherwise blunting might appear where it did not really exist. A picture taken at the end of deep inspiration showed a deformation of the ureter and gave a false impression. Of great importance was the control of the patient; if he was very nervous he should be asked to breathe deeply through the nose. Breathing rapidly through the open mouth would assist in cases where pain was produced, and the patient could be asked to take small breaths or to stop breathing altogether while the picture was taken. There should be a preliminary examination before the pyelography if possible. He demonstrated a slide to show that pyelography with the patient in the vertical position was quite possible.

Mr. A. CLIFFORD MORSON said that correct interpretation was very difficult and required close coöperation between radiologist and urologist. The clinical picture was as valuable as the radiogram, and the pain produced by fluid injection should be compared with the pain the patient complained of. He always used sodium iodide from 15–25 per cent., and had given up the use of antiseptic with it, owing to the irritation caused by oxycyanide of mercury. He showed slides illustrating three cases:—

1. Case of painless hæmaturia. Pyelogram showed one kidney normal with distended calyces and the other wit something protruding on the inner side of the pelvis; th proved to be a squamous carcinoma.

2. A case of stony hard swelling in the left loin with shadow over the iliac crest. The pyelogram was not of muc help; it showed a little stunting of the lower calyces Operation revealed a very large hydatid cyst of the lowe pole, with calcified wall.

3. A case of painless hæmaturia in a boy of 17 with both kidneys palpable. Pyelography showed an abnormal bifid pelvis with elongated calyces, probably a congenital cystic condition.

Prof. E. B. FULLER (Cape Town) said that very valuable information about mobility was obtained by screening the kidney before the injection and watching the fluid go in and the way the pelvis distended. This also gave the best position for centring the photograph.

Mr. C. NITCH asked for an opinion on a case of a girl of 10 with colon bacilluria of six months' duration, and retention. Daily catheterisation had reduced the retention to 8 oz. residual urine. The bladder was inflamed and the neck œdematous and congested. Only 15 c.cm. of sodium bromide would pass in; it showed hydronephrosis on one side. Pyelography under anæsthesia showed that the opposite kidney was normal, as it was in function. If the condition was primarily in the bladder, why was the dilatation on one side only?

Mr. MORSON described similar cases in which unilateral congenital hydronephrosis was associated with occult spina bifida. He explained the one-sidedness by a faulty innervation of the bladder neck, so that one ureter gave way before the other.

The PRESIDENT said that he had found, working with Dr. R. Knox, that 10–12 per cent. sodium iodide gave the same density as sodium bromide, but he had used the latter extensively and satisfactorily. He used 12 per cent. sodium bromide when working with a small renal pelvis, but if he suspected dilatation he used up to 25 or 30 per cent. solutions, because of the difficulty of emptying a large pelvis and the resulting dilution of the injection fluid with urine. He took the first picture when 10 c.cm. had been injected, and if there was then no pain he injected up to 20 c.cm. He showed slides illustrating:—

1. A shadow thought to be a stone. Pyelography showed dilatation of the ureter due to spasm and the dilated calyx above the stone.

2. A large number of small stones in the kidney of a young child.

3. A case of hydronephrosis and dilated ureter with stone.

4. A boy with a stone in each ureter.

5. A stone in the ureter with large destruction of the kidney.

6. A case with attacks of renal colic; the X rays showed nothing, but pyelography revealed a marked kinking of the ureter, probably due to an aberrant artery. He had since learned to disregard kinks; often, as in this case, nothing was found at operation.

7. A case of hydronephrosis where the catheter would only pass in 2 in., but the injection was successful.

8. A case of severe pain in the left side with enlarged kidney and tortuous ureter. At operation the kidney was found to be slightly displaced by tuberculous glands.

9. A case of right-sided swelling with frequency of micturition and normal pyelogram. The swelling was a right lobe of the liver, and the frequency was due to a uterine fibroid.

10. A case that looked like pelvic hydronephrosis; the catheter would not pass up. A year later the condition was a renal hydronephrosis and the catheter was passed satisfactorily.

11. An incomplete filling of a large hydronephrosis which gave a picture like a new growth.

12. A fat patient with hæmaturia from the left kidney. Pyelography showed a flattened top to the pelvis which looked like a growth but was really due simply to flabbiness of the kidney.

13. A horse-shoe kidney, showing the characteristic tail on the inner side of the calyx.

14. A case of polycystic kidney with long calyces.

Mr. WINSBURY WHITE showed slides illustrating:—

1. Marked looping of the ureter with distension of the pelvis. The urine could not be got out, although the catheter passed a normal distance. He wondered whether it was justifiable to run in a fluid, knowing, as in this case, that it could not be extracted.

2. Two cases where the catheter passed up to 30 cm. but no urine drained out. The indigo-carmine test indicated hydronephrosis, and the kidney was removed without pyelography. He did not think pyelography should be done on such cases; the diagnosis was simple without.

3. A case of ureteral stricture with attacks of pain on the left side similar to that of hydronephrosis. The catheter would not pass up in this case either, but the thickened ureter could be palpated.

# SOCIETY OF MEDICAL OFFICERS OF HEALTH.

## MATERNITY AND CHILD WELFARE GROUP.

A MEETING of this Group was held on Jan. 21st, when Dr. HAROLD SCURFIELD, the Vice-President, took the chair. He referred to the death in December last of Dr. R. Woolsey Stocks, the President, and deplored the loss which the Group had suffered. A resolution of condolence was passed.

Dr. REGINALD JEWESBURY (St. Thomas's Hospital and Truby King Institute) then opened a discussion on

### *The Use of Cream in Infant Feeding.*

Fat, he said, was one of the most difficult and important constituents of the infant's diet, and nearly all prepared infant foods were deficient in it. The fat chosen might be natural cream or some other fat. Natural cream possessed the disadvantage of uncertain composition, depending on whether it was separated or centrifugalised cream, besides having all the ordinary disadvantages associated with cow's milk. He had found emulsified fats more satisfactory in use, and recommended a 50 per cent. emulsion containing cod-liver oil. The introduction of such a fat must in all cases be gradual. New Zealand cream was an example of such an emulsion. It was made from a recipe carefully compounded by the director of infant welfare in New Zealand, and was intended for use throughout that country. It was manufactured in a New Zealand Government factory, and Dr. Jewesbury had found it most satisfactory in use, readily assimilable, and sterile. It kept indefinitely, contained the vitamin intact, and had the high caloric value of 180 per oz. The composition was 50 per cent. fat, two-thirds of this being animal oil, including fresh New Zealand butter and cod-liver oil, and one-third vegetable oil, mainly pea-nut oil; 40 per cent. sugars, mainly dextrose; and a little lactose. The addition of the pea-nut oil was found of great assistance in promoting the digestibility of the animal oils. Whether this particular cream appealed to people or not, he strongly advocated the use of some such product of uniform content in infant welfare work throughout the country.

Dr. E. A. BARTON (University College Hospital) reminded his hearers that the digestibility of fats was very variable and was in inverse ratio to their melting points. Although human and cow's cream seemed comparable in this respect, in practice the infant had difficulty at first in taking a milk mixture containing cream in similar proportion to breast milk. He believed that artificial creams should only be used when clean cow's cream was unobtainable, as it was in poor districts during the war. Accordingly he had endeavoured to design a synthetic cream which would be cheap, clean, and readily assimilable, and which, in contrast to Dr. Eric Pritchard's early synthetic cream which he had previously used, would contain the fat-soluble vitamin A. With help from Dr. C. H. Hampshire a cream had been derived from the emulsification of beef suet, and this they had found readily tolerated by infants. Beef suet had a higher melting point and its digestibility was less than that of butter fat, but only to the extent of about 4 per cent. The fat content was 25 per cent.

Dr. DONALD PATERSON (Great Ormond-street and Infants Hospital) said that he believed synthetic creams to be an unnecessary complication of ordinary cod-liver oil emulsions. He thought that people erred in exaggerating the chances of too little fat being given, and stated that the curds in infant stools were nearly always fat curds. Cases suffering from this condition were typically the cases that developed summer diarrhœa. The fat tolerance of the infant was easily overstepped, and as fat was slow in leaving the stomach it was often, if given in excess, a cause of vomiting when the next feed was given. The vitamin content of ordinary cream varied greatly and was liable to be deficient in winter. He believed in giving all children cod-liver oil for its vitamin content, and this was done at Great Ormond-street. The psychology of the mother was a factor influencing the child's tolerance of fat. He advised giving cod-liver oil before instead of after three of the daily feeds.

Dr. J. F. Haines (assistant medical officer, St. Pancras) described the process of fat digestion in some detail, and stated that while the fine state of emulsification of fat in breast milk contributed to its ready digestion by the infant, it was possible that each kind of fat required its own enzyme, and that foreign fats given to the infant suffered on this account. Everyone agreed that it was necessary to approximate as nearly as possible to breast milk in composition and in ratio of constituents, and he thought that for this reason milk fat in the form of cream or butter was better than any vegetable or other animal fat. He had tried many synthetic creams, but for years now had advised the addition of fresh butter to infant feeds in a poor district where expense and simplicity had to be considered. His results had been extremely satisfactory. The percentages were easily calculated; one-quarter of a teaspoonful of butter in a 3 oz. feed raised the percentage of fat by 1. Where good cream was obtainable he found the old formula approximating to breast milk excellent. The important point was to introduce fat into the feeds slowly and gradually, remembering the infant's tendency to intolerance; if necessary alkalis and biliary stimulants should be given as well. Cod-liver oil given in a similar manner was the best substitute for milk fat.

Dr. W. J. Cox (medical officer of health, Watford) gave some results of administering Vitoleum cream, and Dr. Flora Shepherd dealt with the possibility of infection from cow's cream or butter.—Dr. Margaret Alden quoted a series of letters from various medical officers to whom she had written asking for information regarding their practice in the use of fats. Cod-liver oil seemed to be the fat in general favour.—Many other members also took part in the discussion, in closing which the Chairman referred to the pasteurisation which is, or used to be, the natural procedure in the making of Devonshire cream and Devonshire butter. It was decided to appoint a subcommittee on cream to report to the National League for Health, Maternity and Child Welfare in due course.

## JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.

At a meeting held on Jan. 26th Dr. A. Hynd gave a lecture-demonstration on the

### *Estimation of Blood-sugar.*

In introducing the subject the lecturer referred to the various processes which tend to keep the sugar content of the blood within normal limits. As the estimation of blood-sugar is carried out to throw light on the behaviour of one or other of these processes, the results can be of value only when the processes other than that under investigation are maintained at a constant level of activity. It was then pointed out that, as the glucose present in the blood exists in the free state and not combined with colloids, the sugar is not precipitated on deproteinisation. Also as, under normal conditions, the sugar contents of the corpuscles and plasma of human blood approximate to each other closely, there is no advantage in using plasma rather than whole blood for the determination. Consequently, the estimation can be carried out on a much smaller quantity of blood than would be necessary if it were essential to employ plasma.

Dr. Hynd indicated that the estimation of blood-sugar may be subdivided into two parts: (1) the removal of protein, and (2) the determination of the sugar content of the protein-free filtrate. The various methods for deproteinising blood were reviewed, and the fact that so many methods have been devised for this purpose indicates that the removal of protein from blood, in such a way that the subsequent sugar estimation is not interfered with, is no easy matter. The methods for the determination of the sugar content of the protein-free blood filtrate all depended on the reducing property of glucose, and were either colorimetric or volumetric processes. Although the former are much more rapidly carried out, and can be employed advantageously when a large number of estimations must be made, they are not so reliable as the volumetric methods. Of these the most useful for clinical work are the methods devised by Hagedorn and Jensen and by MacLean.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF SURGERY.

A meeting of this Section was held on Jan. 15th with Mr. R. C. B. Maunsell, the President, in the chair.

### *Double Vestibulotomy.*

Dr. Horace Law and Dr. Geoffrey Bewley showed a patient on whom Dr. Law had performed this operation.

She was a girl aged 7 years who developed acute suppuration of the left middle ear on Nov. 27th. This appeared to progress favourably, but a week from the onset she complained of headache and nausea and had some convulsions. A tentative diagnosis of meningitis was made, but the cerebrospinal fluid was found to be clear and sterile though under considerable pressure. Shortly afterwards her pupils became unequal, the left being dilated; there was nystagmus to the right, and the eyes tended to deviate to the same side. Her knee-jerks were equal and normal; there was no ankle clonus and no Babinski's sign. Double vestibulotomy was done, and in a few hours the nystagmus, which before had been to the right, changed to the left; the pupils became equal and the temperature fell to normal. Subsequently the child did not develop any signs of giddiness, and she is now practically well.

Dr. Bewley said that before the operation the child was in a moribund state, and he thought that she would not have lived more than a few hours.

### *Foreign Body in the Brain.*

Sir William Wheeler exhibited a patient, aged 21, who was wounded in the head in May, 1921.

During some street fighting he received what was then thought to be a small scalp wound to the right of and above the occipital protuberance. He was not detained in hospital. At the time of his wound he noticed music in his ears, as if there was a band with drums in the locality. A fortnight later he was smoking a cigarette when he noticed a black dot in his right lateral field of vision. The speck moved medially, growing larger and becoming brighter until it appeared as a blinding light in the centre of his visual field. At this stage he became totally blind. He never lost consciousness but his memory was stimulated, and he saw men firing at him and believed that he was surrounded by some of his companions. The attack was followed by headache and vomiting. These attacks lasted about 20 minutes and recurred once or twice a month for four years. There was no olfactory disturbance. In the intervals he was well, but the constant appearance of the black spot made him mentally morbid.

The results of clinical examinations were entirely negative; there was no paralysis, motor or sensory; there were no alterations in the reflexes, and both fundi were normal. The fields of vision was not accurately examined before operation. X ray examinations disclosed that the nickel case of part of a conical bullet was lying in the base of the brain, just behind the petrous portion of the temporal bone at the level of the eminence in the superior semicircular canal. To approach the bullet in a direct line it would have been necessary to open the skull behind the vertical line, dividing the mastoid into equal parts. The direct route would have led through the sigmoid portion of the lateral sinus and some of the posterior branches of the middle meningeal artery. The skull was opened at a level above the location of the bullet, and when the meninges were divided a finger was passed under the temporal lobe in front of the cerebellum. After some difficulty a feeling of resistance was detected with the finger, and with the latter in situ a forceps was pushed through the temporal lobe in its direction. A mass about the size of an olive could now be located and was enucleated. There appeared to be a line of cleavage between the mass and the brain substance. On removal the tumour proved to be a mass of fibrous tissue incapsulating the conical point of the bullet. Before it could be extracted it became necessary to nibble away bone towards the base of the skull and the sigmoid portion of the lateral sinus was wounded. Control of the bleeding was not difficult. During the removal some brain matter on the lateral surface of the temporal lobe was injured and removed. In bulk the brain matter sacrificed was about the size of the tumour. At the close of the operation the bone was not replaced and no osteoplastic flap was made.

The after-history was uneventful, and a month after the operation the patient appeared quite well. He had no recurrence of his previous attacks.

It appeared that the area involved in this case was the association area which lay between the visual area behind and the portion of the brain to do with hearing, in front, and it was interesting, said Sir William Wheeler, to correlate these findings with the clinical history given by the patient. The three main points in the history were: the sounds of band music on the day he was wounded; the distorted visual phenomena occurring on an average twice a month for over four years; and the memory, during each attack, of troops firing at him and the feeling of being surrounded by his friends. He surmised that the association centre in the brain from which the foreign body was extracted was one of the habitats of the intellect which brought to memory hearing and sight. He ventured to think that it was the development of such a centre—absent at birth and in the lower animals—which accounted (inter alia) for the fact that Beethoven could write and conduct his symphonies at a time when he was totally deaf.

Sir William Wheeler also read a paper on a case of Colonic Infantilism.

## SECTION OF PATHOLOGY.

A MEETING of this Section was held on Jan. 8th with Prof. J. W. BIGGER, the President, in the chair.

Dr. J. LAIT exhibited three specimens of

### *Hypernephroma.*

These tumours, he said, were not commonly met with, though they formed a high proportion of renal new growths. He had encountered three cases in three months, which he considered unusual; two were removed by operation and one was discovered at an autopsy. Hypernephromata most commonly occurred between the ages of 35 and 60. One of the specimens had been removed from a boy aged 15, but the disease was rare in childhood.

The first specimen was removed from a woman aged 38, who had complained of painless hæmaturia for some months. The tumour was palpable and hypernephroma was diagnosed. At the operation the tumour was found to have extensively invaded the renal vein which was ligated and removed with the kidney. The specimen was a typical hypernephroma.

The second specimen was from a boy aged 15. He had been suffering from hæmaturia off and on for 12 months. On Oct. 1st, 1925, he injured his side in falling, and this was followed by considerable hæmaturia. During cystoscopy gentle pressure over the affected side was followed by profuse hæmorrhage from the corresponding ureter. The tumour was not palpable. It was removed by operation. The kidney was slightly enlarged, with subcapsular hæmorrhages and several calcified nodules over its lower pole. The pelvis was distended and apparently filled with blood clot. An incision was made into the kidney and a tumour was found occupying the lower half of the organ and invading the pelvis, causing its distension. It was very hæmorrhagic. Microscopic examination revealed an epithelial tumour formation, hypernephromatous in type. Sections also showed numerous small calcified nodules, cancellous bone, and much hæmorrhage.

The third specimen was discovered at a post-mortem examination in a woman aged 50. The tumour was the size of a fœtal head and there was practically no kidney substance left. The renal vein was involved. There were metastases in the lungs and liver, but the spleen was not involved.

Discussing the ætiology of hypernephroma, Dr. Lait asked whether it was usual to find cartilage and bone, as in the second case. Was the tumour correctly named? He believed that many of these tumours had a renal origin.

### *Tumour of the Humerus.*

Dr. F. S. BOURKE showed a specimen from a patient aged 31.

He was admitted to hospital in May, 1925, with a swelling of the elbow of two months' duration. At first it was thought to be tuberculous, and an incision was made. Dr. Bourke had considered that the tumour was an endothelioma, but Prof. Wigham, who had made a paraffin section, had said that he thought it was a cancer, the primary growth being probably in the thyroid or in the prostate. The man was examined very carefully, but no primary focus was found. In June the arm was removed, because it was thought that the tumour was an endothelioma and there was the possibility that it was merely a local growth. The patient remained in hospital until September, when the upper part of the right thigh began to swell and another tumour was found there. He was given deep X ray treatment, but gradually went downhill and developed secondaries all over the body. In October he developed bladder obstruction and an operation was done. It was found that the obstruction was from the prostate. Before the operation the patient said that six months previously he had had a hæmorrhage from the bladder, which he had not mentioned until then.

Dr. W. D. O'KELLY said that from the original section it would have been very hard to diagnose cancer, though the second section was full of it.

At the same meeting Dr. O'KELLY showed an economical lamp-holder for microscopical work, and Dr. M. M. MERRICK read a paper on the Bacteriological Findings in Vaginal Discharges, based on the results of a series of cases investigated by her and Dr. D. W. Douglas in the Coombe Hospital.

## SECTION OF ANATOMY AND PHYSIOLOGY.

A MEETING of this Section was held on Jan. 22nd, at which Dr. C. M. WEST, the President, made a communication on Hypospadias, and Dr. W. R. FEARON demonstrated a new Colour Test for Indoxyl and a

### *Simple Clinical Test for Bile.*

The bile-test he proposed is as follows: to 5 c.cm. of urine add an equal volume of glacial acetic acid and 1 drop of Milton. The presence of bile is shown by the development of a deep green colour, which changes to dark blue and then to purple on the addition of another drop or two of Milton. In character, he said, the test was similar to the Gmelin-Hammarsten reaction, involving the conversion of the pigment bilirubin into a series of coloured oxidation derivatives. Of these the blue compound, bilicyanin, was the most intense, and its recognition determined the delicacy of the test. The glacial acetic acid liberated the bilirubin, and acted as a solvent for the pigments. In the absence of Milton (a proprietary preparation of sodium hypochlorite) other oxidising agents might be used, such as 3 per cent. hydrogen peroxide, followed by gentle warming. But the results obtained with Milton were much more delicate. The test would detect 1 part of bilirubin in 100,000 parts of urine, thus comparing favourably with the other direct tests for bile.[1]

## BUXTON MEDICAL RESEARCH SOCIETY.

AT a meeting of this Society held at the Devonshire Hospital, Buxton, on Jan. 12th, Dr. J. A. RYLE (London) delivered an address on

### *Hyperpiesia.*

After a tribute to the late Sir Clifford Allbutt for his work in delimiting hyperpiesia from renal and other forms of hyperpiesis on the one hand, and from senile or decrescent atheroma on the other, Dr. Ryle suggested that although it was interesting to speculate on the existence and nature of a pressor substance, it was at present more profitable to bear in mind certain known ætiological factors. We should not neglect older methods of clinical study in our eagerness to unearth specific causal agents. He regarded bacterial and intestinal toxins as unlikely factors, partly because most of these toxins have a depressor rather than a pressor effect, and partly because the majority of hyperpietic patients have been robust and healthy individuals with a striking immunity from infection. Diathesis was of particular importance in hyperpiesia. It had long been recognised that hyperpiesia was more common in robust individuals, and that there was frequently a family history of deaths from cerebral hæmorrhage or cardiac defeat in the fifth and sixth decades. An analysis of 50 cases of hyperpiesia which he had made had given the following results: 62 per cent. of the patients were recorded as robust, healthy, stout, plethoric, or hypersthenic; 18 per cent. as average; 14 per cent. as of poor physique; and 6 per cent. as lean and nervous. The outstanding characters of the hypersthenic diathesis were a full habit, a broad chest, a good colour, and a pronounced tonicity of both skeletal and plain muscle. The stomach was hypertonic and the appetite and capacity for work were exaggerated. Diathesis could be defined as an inherent liability to retain the impress of certain adverse stimuli. Patients with a physiological hypertonus of vascular plain muscle were more likely to retain permanently the effects of such stimuli as overwork, over-eating, and over-anxiety, which were known to raise the blood pressure. Infections only appeared to play an important part in the small group described as of poor physique and in a few of the group called average. The high incidence of the female cases — 54 per cent. as compared with 46 per cent. of males in his series— was probably due to the inclusion of cases of menopausal hyperpiesia. After discussing therapeutic measures such as alteration in mode of life, holidays, dietary, weight-reduction, venesection, and diathermy, Dr. Ryle suggested a plan for prophylaxis based on the popularisation of periodic physical examinations after the fourth decade, attention to family history and physical type, and the systematic use of the sphygmomanometer.

---

## LIVERPOOL MEDICAL INSTITUTION.

A PATHOLOGICAL meeting was held on Jan. 21st, when Mr. K. W. MONSARRAT read a paper on the

*Ætiology of Chronic Gastric and Duodenal Ulceration.*

He reviewed the evidence on the question of infection, mentioning the work of Bolton, Türck, Dawson, Rosenow, and others. He then passed to the consideration of the rôle played by alterations in the gastric chemistry, and argued that such alterations could not be considered the chief agency in the production of chronic ulcer. In the third place he reviewed the work of Cannon, Carlson, Rogers, and others on disorders of gastric rhythm and tonus. He drew the following conclusions from his review of the subject:—

1. There is no satisfactory evidence that chronic gastric and duodenal ulceration is primarily due to direct invasion of the stomach or duodenal wall by specific organisms.

2. Chronic gastric and duodenal ulceration is not caused by alterations in the chemistry of the gastric secretions.

3. The evidence available points to alteration in gastric rhythm being the primary morbid condition which, when persistent, leads to the development of ulceration.

4. The site of the ulceration is the site of maximum impact of gastric contents, whose normal neutralisation has been interfered with by the altered gastric rhythm.

5. The gastric secretions, innocuous to the stomach wall under normal conditions, cause irritation and eventual ulceration when the gastric rhythm is altered; trophic changes may also prepare the way for this action.

6. The fundamental condition on which these morbid changes in gastric motility and rhythm depend is doubtless a disorder of gastric innervation, which may have its origin in toxic influences or psychic influences, or in reflex influences from disease elsewhere. The innervation of the stomach is not, however, so completely analysed as to make it possible to say whether these influences bear on an autonomic gastric system, or whether they affect the stomach by way of the vagus or sympathetic. There is, however, some evidence that in the gastric type which is usually associated with duodenal ulceration there is some inhibition of impulses by the splanchnic path, and that in the gastric type which is usually associated with gastric ulceration it is the vagus impulse which is depressed.

Mr. Monsarrat pointed out that there were many questions still unsettled, particularly in regard to the part played by infection, by alterations in the gastric secretion, and by influence through the nervous system.

# Reviews and Notices of Books.

FORENSIC MEDICINE AND TOXICOLOGY.

*Buchanan's Text-book of Forensic Medicine and Toxicology.* Ninth edition. Revised by JOHN E. W. MACFALL, M.D., D.P.H. Liverp., M.B., Ch.B. Vict., Ph.C., Professor in Forensic Medicine and Toxicology, University of Liverpool. Edinburgh: E. and S. Livingstone. 1925. Pp. 445. 15s.

THIS work was formerly known as Husband's Forensic Medicine and it included public health. The eighth edition, brought out by Dr. R. J. M. Buchanan, dealt only with forensic medicine, the public health section being published separately. The present (ninth) edition is entrusted to Dr. MacFall.

The first section dealing with forensic medicine is clearly and concisely written, with much material arranged in tabular form, and is profusely illustrated. The tables of measurement of structures make use of the unfamiliar unit of "lines"—e.g., 2 inches 8 lines. A line (one-twelfth of an inch) is a convenient term, but so rarely employed as perhaps to require explanation. The chapter on blood stains is complete and accurate with one exception. This is the italicised statement that the guaiacum test "reacts to no coloured substance except blood." If this were so, there would be no need for other tests except those determining the species from which the blood was derived. Insulin poisoning, producing hypoglycæmia, might have been included in the differential diagnosis of states of coma.

In the second section which deals with toxicology the author has attempted to put much matter in a small space, with the result that analytical details suffer. The difficulty of condensing such details is obvious, but the reader may be led into serious error, when he attempts to perform tests suitable for pure substances on viscera, medicines, or remains of poison in glasses, unless he receives the fullest guidance in the methods of isolation of the suspected substance in a state of purity. Objection is taken by the author to the Reinsch test owing to the danger of impure hydrochloric acid or copper, whereas in discussing Marsh's process this question is dismissed by stating that absolute purity of reagents must be ensured. The Marsh test is much more delicate than the Reinsch test, therefore the purity of reagents is far more important. In practice purity of reagents is a continual worry when the Marsh test is being used, whereas with the Reinsch test, using ordinary "arsenic-free" reagents, there is seldom need for anxiety. In this connexion it is surprising to find no mention of the electrolytic process for Marsh's method. The analysis of material containing sulphuric acid is unsatisfactory and difficult to understand. If the details were followed as here given, deduction from results would not be correct, if indeed any result was obtained at all. The iodic acid test for morphine is incompletely set out, and the most important test for cocaine—namely, the permanganate test—is not among the six tests described. Poisoning by muriatic acid is stated to be so rare that the symptoms have not been well studied. Yet in the Registrar-General's reports for 1921-23, 210 deaths are given as due to hydrochloric acid and only 20 for both nitric and sulphuric acid.

Students and practitioners will find the parts of the book which are of chief interest to them—those dealing with symptoms, post-mortem appearances, and treatment—reliable, and as detailed as possible in a work of this size. The index is good and misprints are few.

ON THE PANEL.

By a Panel Doctor. With a Preface by C. M. WILSON. London: Faber and Gwyer, Ltd. (The Scientific Press). 1926. Pp. 204. 6s.

THIS is a useful little book recording the experience on the panel side of practice in a country town. The author and his partner are responsible for 2500 panel patients, and the various chapters give a simple and candid account of what they do and how they do it, of what are their difficulties and how they surmount them, indicating at the same time many places where a better public understanding of insurance practice will automatically remove situations that are now embarrassing. The young practitioner may be warmly advised to read the first eight chapters, though this is not to suggest that he will not learn much that is useful from the rest of the work. But the earlier part of the book is full of practical advice to the man starting in practice as to the right methods of dealing with the insured man and woman—methods which necessitate the cultivation of a real sympathy with the general position as well as with the individual temperament of panel patients. Although the author nowhere says it in words, he is considering throughout the situation of a man who is in partnership, and so consistently is his advice coloured by a knowledge of the value and advantages of partnership, that he may be said to imply that the only reasonable method of entering upon panel practice for the young man is in association with a senior of assured position.

In dealing at the end of the book with the question of a State Medical Service the author reaches the conclusion that no adequate scheme for such a service, or for a greatly extended insurance scheme, is likely to be other than extremely expensive; and he demonstrates, along lines that are mostly familiar, that to spend a great deal of money in the institution of a State Medical Service would be to spend it badly, if only because the valued right of the patient to choose his own doctor would necessarily go. He sets out fairly the arguments in favour of the socialistic plan, such as removal of the doctor's anxiety with regard to financial position, the possibility of starting without capital expenditure, and the more even distribution of doctors in accordance with the density of the population, but counters them with the opinion that the loss to the patient of the free choice of doctor is fatal to the scheme.

### LIFE OF FLORENCE NIGHTINGALE.

By Sir EDWARD COOK; Abridged and revised by ROSALIND NASH. London: Macmillan and Co. 1925. Pp. 401. 15*s*.

Sir Edward Cook had intended to write a "Short *Life of Florence Nightingale*" as a pendant to his monumental work in two volumes reviewed in THE LANCET in 1913 (ii, 1483). His death prevented the carrying out of this project, but Miss Nash has produced an admirable abridgement of the larger work together with some fresh matter, details of which will be found in the preface. The fact that the medical services of the Navy and Army during the Great War were the subject of universal admiration was in great part due to the initiative and passionate energy of Florence Nightingale during and after the Crimean War, a period of her life which by its dramatic incidents and its awakening effects upon the national conscience rather overshadows her admirable social services. Still her work in the Crimea and what followed as a corollary, the reorganisation of the War Office with the aid of Sidney Herbert, were events of outstanding importance. When the Crimean War broke out we were so unprepared that the fuses for the shells of the first battering train sent out had been in store since Waterloo and there were not enough shells fully to furnish it. The medical arrangements were beyond contempt, and no wonder when the Director-General of the Medical Department in London was under five distinct masters—the Commander-in-Chief, the Secretary of State, the Secretary of War, the Master-General of Ordnance, and the Board of Ordnance. There is a passage in Livy (Bk. II., 57) which *mutatis mutandis* exactly describes the situation: "While the tribunes and the consuls each tried to bring everything under their respective authority there was no central unity of command, the nation was distracted and torn in two, and the thing sought for appeared to be rather in whose hands power should be, than that its safety should be preserved." The Government, with the exception of Herbert, most of the medical officers at the front, the old soldiers, the camp and port authorities, were all afraid or unwilling to move. Into this blood-stained welter of ignorance and officialism Florence Nightingale came to reduce the chaos to order; how she did it is known to all the world. Afterwards she continued her work, to the lasting benefit of hospitals and public health throughout the world.

### FRACTURES AND DISLOCATIONS.

*Treatment of Fractures and Dislocations in General Practice.* Second edition. By C. MAX PAGE, D.S.O., M.S. Lond., F.R.C.S., Senior Surgeon to Out-patients, St. Thomas's Hospital, &c., and W. ROWLEY BRISTOW, M.B., B.S. Lond., F.R.C.S., Surgeon to the Orthopædic Department, St. Thomas's Hospital. London: Humphrey Milford, Oxford University Press. 1925. With 118 figures in the text. Pp. xiii + 270. 12*s*. 6*d*.

Two years ago (THE LANCET, 1923, ii., 1355) we welcomed the first edition of this book, for which we predicted a popular success with surgeons as well as with the practitioners for whom it was primarily designed. The title has been altered to include dislocations; the additional matter certainly increases the value of the book, of which the price remains unchanged. Some figures have been withdrawn, but more have been added. The new chapter on dislocations in general contains much sound advice, and the sections devoted to dislocations in the chapters dealing with the various bones should be of great utility. The classical but rough-and-ready method of reduction of a dislocated shoulder by the heel in the axilla has fallen out of use and the authors of this book teach that it should never be employed. The method favoured is essentially that of Kocher. Other dislocations are shortly but adequately dealt with. This little book should receive a permanent place among modern surgical handbooks.

## JOURNALS.

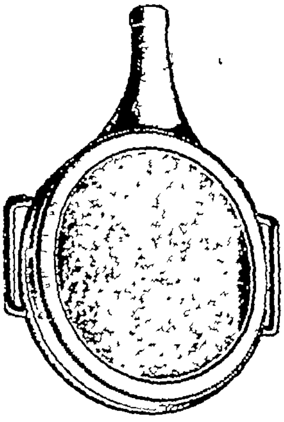
JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXIX., No. 1. Pp. 1–130. January, 1926.—The Identification of the So-called *B. mycoides corallinus* as a Streptothrix, by Vera B. Reader (London). Some particulars of the pigment and its spectrum are also given.—The Production of Experimental Endocarditis with Pneumococci and Streptococci in Immunised Animals, by H. D. Wright (London). Endocarditis can be produced in specifically immunised animals, and in some cases a progressively increasing septicæmia with marked antibody production has been seen such as occurs in subacute infective endocarditis in man, but the conditions which determine the occurrence of this state have not been determined.—Inhibition of Bacterial Growth by Some Amino-acids and its Bearing on the Use of Tryptic Digests as Culture Media, by J. Gordon and J. W. McLeod (Leeds). Some amino-acids (e.g., taurine, alanine) favour growth, some (e.g., cystine, tryptophane) are inhibitory, and some (e.g., arginine, tyrosine) are indifferent. Indol is a powerful antiseptic, and tryptophane probably owes its action to this. Serum protects bacteria against amino-acids and must be added to tryptic digest media to make them efficient.—A Laboratory Epidemic in Rats due to Gaertner's Bacillus, by N. D. Ball and C. Price-Jones (London). A running epidemic had killed 10 rats out of 602 in the course of 12 months. The whole rat population of the animal house, consisting of apparently healthy animals, was then killed and examined; Gaertner's bacillus was isolated from the spleen of 13, three of which also gave positive agglutinations; 15 others agglutinated without yielding the bacillus.—Immunological Notes, by A. T. Glenny, C. G. Pope, Hilda Waddington, and U. Wallace (London). The precipitate obtained in the Ramon testing of toxin antitoxin mixtures is actively antigenic. Toxin containing 0·5 per cent. phenol is more easily destroyed by heat than uncarbolised toxin, and the same is true, but to a less degree, of trikresol. Carbolised toxin-antitoxin mixtures may become toxic on evaporation because the phenol destroys antitoxin faster than toxin. Formaldehyde, 0·2 per cent., rapidly reduces the antitoxic value of serum. Toxin or toxoid precipitated with potash alum has a high *antigenic value. Toxoids which fail to flocculate in* Ramon tests may be good antigens.—Chordoma: a Review with Report of a New Sacrococcygeal Case, by M. J. Stewart and J. E. Morin (Leeds). A useful and comprehensive account of this rare tumour.—A Sacrococcygeal Chordoma, by W. A. Alexander and J. W. Struthers (Edinburgh). These papers were reviewed at some length in The Lancet last week (p. 248).—On the So-called Calcification in the Basal Ganglia of the Brain by E. W. Hurst. Deposits which stain blue-black with ordinary hæmatoxylin mixtures are fairly common in the lenticular nucleus either in the walls of the blood-vessels or as isolated spherical bodies in the tissues; the author found the former 50 times and the latter 68 times in 100 brains. They have been generally supposed to represent calcification, but neither the author nor anyone else has been able to produce definite evidence of this. All the vascular deposits and most of the isolated bodies contain abundant inorganic iron, connected with the high iron content of the globus pallidus.—Experiments on the Influence of Fatigue on Infection, by A. E. Boycott and C. Price-Jones (London). Exhaustion in a rotating drum has no influence on the mortality of rats inoculated with Gaertner's bacillus, but markedly increases illness and deaths in animals infected by feeding. Repeated exhaustion does not break down the resistance of the rat to tubercle. Fatigue is accompanied by a fall of body temperature to 85° F., or even lower.—The Nature of the Movements of the Omentum, by H. Florey and H. M. Carleton (Cambridge and Oxford). The omentum is incapable of moving itself. It is passively moved about the abdomen by posture, peristalsis of the bowels, and diaphragmatic movements.—The Action of Extracts of Mesenteric Lymph Glands on Leucocytes, by R. H. Mole (Moukden). Extracts of the glands of a spleenless rabbit cause leucocytosis in spleenless rabbits, but not in normal animals.—The Number of Lymphoid Follicles of the Human Large Intestine, by C. E. Dukes and H. J. R. Bussey. The authors enumerated the follicles in 117 cases by a simple technique. The average number per square centimetre is about 3¼ with a range of about 1 to 7. Children have more than adults, and there is an increase of 80 per cent. in passing from the ascending colon to the sigmoid.—Alum Carmine for Counterstaining Weigert-Pal Preparations, by J. *Anderson (London).—Dissecting Diverticula of the* Appendix, by J. A. Jenkins (Dunedin). A curious condition of which the author has seen six examples.—Staphylococci and Rheumatoid Arthritis, by H. W. Crowe (Harrogate). In *two* cases of rheumatoid arthritis cultures of staphylococci were obtained from the tissues about the joints obtained at operation.—Immunisation against *B. welchii*, by T. Dalling and J. H. Mason (London). The toxin and antitoxin can be accurately titrated by intravenous injection in mice. Active immunisation of sheep protects their lambs from a diarrhœal disease associated with the bacillus.—Vaccine *Treatment of Canine Leptospiral* Jaundice, by T. Dalling and C. C. Okell (London). A sterile carbolised emulsion of the liver of infected guinea-pigs is an effective vaccine for dogs against "the yellows."—Hæmagglutination by Horse Serum and Jaundice in Mice, by C. C. Okell and G. I. Steed (London). Some samples of horse serum agglutinate mouse red cells and on intravenous injection cause severe anæmia, jaundice, and death.—Combined Schick Test and Diphtheria Prophylactic: Combined Diphtheria-scarlet-fever Prophylactic, by A. T. Glenny and Hilda Waddington (London). A mixture of toxin, toxoid, and antitoxin can be prepared which contains the same amount of toxin as a Schick-testing dose and has at the same time enough toxoid to replace the first immunising dose of toxin-antitoxin mixture. This saves time and trouble. Scarlet fever streptococcus toxin may be added to toxin-antitoxin mixtures in considerable amount without reducing the efficacy of the latter; it is hoped by such mixtures to immunise against scarlet fever and diphtheria simultaneously.—Some Points Regarding the Nutrition of *B. typhosus* and *B. coli*, by A. Piney (London).—*Attenuation of Tubercle* Bacilli extending over a Period of Nineteen Years, by N. Raw (London). Human, bovine, and avian strains have become non-pathogenic.—Carcinoid Tumour of Appendix with Large Pelvic Deposits, by M. J. Stewart and A. L. Taylor (Leeds). Carcinoid tumours probably arise from the specialised cells of the crypts of Lieberkühn known as Kultschitzky's cells; they are the commonest form of tumour of the appendix, occur mostly in relatively young subjects, and rarely metastasise. In the present case two masses were removed from the pelvis as well as the appendix with the primary tumour and the patient is alive and well ten years later.—Carcinoid Tumour of Meckel's Diverticulum, by M. J. Stewart and A. L. Taylor (Leeds).

# New Inventions.

## A STETHOSCOPE FOR RECORDING BLOOD PRESSURE.

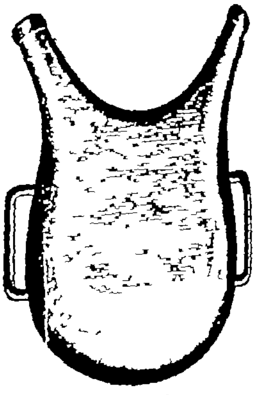
This stethoscope differs from others in the fact that it is set at right angles to those in ordinary use. This has many advantages as it obviates the former necessity of standing straight in front of the part to be auscultated and so avoids the necessity of undressing. Also it avoids the disturbance of bed patients, who are in pain, or who must lie on their backs, as the backs of the lungs can be examined whilst in that position. The heart may be examined whilst the patient lies face downwards and so is in close apposition to the chest wall. The new model is provided with side fixtures to enable one to fix it in situ for use with the sphygmometer in recording blood pressure, for which purpose it is especially suitable. It may be used either with or without a diaphragm. These chest-pieces are made single and double. The single is joined to the binaural frame with a Y-shaped fitting. I prefer to use the single as it is readily manipulated and has less friction sounds, whilst it conveys the required sounds as well as any other stethoscope. The illustrations show the two forms.

Fig. 1.



For single tube.

Fig. 2.



For two tubes.

These chest-pieces can be had from all medical instrument manufacturers.

W. C. Minchin, M.D.

funds to be made available for urgent and necessary extensions of the service. This would, of course, involve legislation, but amendment of the Insurance Acts is rendered the more urgent by the risk of diversion in some other direction of these surplus funds. When, in the course of Poor-law reform, now contemplated by the Ministry of Health, the county councils come to exercise general supervision over the local health services as a whole, the time may well be opportune for some linking up of the insurance services with hospital provision and nursing facilities, both of which are urgently needed by insured persons. The final Scottish evidence before the Commission made it appear that an extra 3*s*. per annum per insured person would cover extension of services to include aids to diagnosis, second opinions, and hospital benefit.

The Commission has worked long and *faithfully*, and when its report is presented a heavy responsibility will rest on any legislature which fails to see that its recommendations are not promptly dealt with. They will necessarily be numerous, and some will be drastic; these facts will not excuse procrastination, as they have on other occasions when Royal Commissions have reported upon matters of national health.

◆

## SAFETY IN RADIOLOGICAL WORK.

SOME publicity has been given to the action of the authorities at the Coventry and Warwickshire Hospital in giving the contract for new X ray apparatus to Germany instead of to the British makers on the ground that, owing to the British methods of protection adopted, the apparatus was much more costly; it was also said to be more cumbrous in action than the apparatus purchasable from, and commonly used, in Germany. The published accounts of this action by the authorities of the hospital concerned may well be correct, and we do not think that the facts concerning the apparatus are seriously in dispute. It would be surprising if British X ray apparatus did not cost appreciably more than German, in view of the much greater importance attached in this country to the question of protection of the operators.

In this country a very important step forward was taken when in 1921 an X Ray and Radium Protection Committee was appointed, under the chairmanship of Sir HUMPHRY ROLLESTON, with the duty of formulating and detailing measures of safety for those engaged in this potentially dangerous work. Their first report was quickly followed by another, amplified in the light of newer knowledge, upon the harmful effects of the radiations. This action was followed by other countries, and it may be said that the measures of precaution recommended by France, America, and the Scandinavian countries show that just as serious a view is taken abroad of the consequences of repeated doses of radiations as was taken here. We believe that the standards of safety adopted in Germany are not so rigorous and, as a result, there is no doubt that some German X ray apparatus is much more lightly built and is probably quicker in
ction than that which finds official acceptance here.
he question that now arises is, are authorities whose
ies involve the spending of money often sub-
bed voluntarily by the public, justified in placing
s in Germany for such apparatus on these
ds? Sometimes it is necessary to go to other
ies for radiological apparatus, but no such
y arises here. We are convinced that the
recommendations are the minimum consistent
ty to the operator, and we would urge upon

the authorities concerned a reconsideration of their decision. Even on the lowest grounds, it might be suggested that if they pay less for the apparatus in the first instance, because it is not so well protected as the British apparatus, they may in years to come have to pay compensation for harm imposed upon those who use the apparatus. Moreover, no organisation which is established for the purpose of healing the sick can be justified in economies which might expose their staff to avoidable dangers. The Protection Committee of this country has had the great advantage of working intimately with the National Physical Laboratory on this subject. The laboratory not only issues certificates upon parts or complete sets of apparatus stating whether the requirements of the Protection Committee are being met, but the staff are able to send experts to inspect installations under actual working conditions.

The fact that personal inspection by the National Physical Laboratory has extended to over a hundred centres speaks well for the way in which the aims of the Protection Committee are being met throughout the country. Far from the recommendations made by them meeting with opposition, there is ample evidence to show that nearly everywhere authorities are anxious to adopt them. Those concerned with the administration of the Coventry and Warwickshire Hospital are, as far as we know, exceptional in the attitude they have adopted, and it remains to be seen whether their subscribers will approve of it. It must be admitted that no absolute guarantee of safety to those engaged in radiological work can be secured by any apparatus, but a strict adherence to the general lines of safety recommended in this country has gone a long way to lessen risks, and the advice of the Protection Committee should, we think, be adopted even if it involves increased outlay.

◆

## THE VIRUS OF FOOT-AND-MOUTH DISEASE.

IT is doubtful whether any ailment, not even excepting cancer and tuberculosis, has been more frequently mentioned in the public press during the last few years than foot-and-mouth disease. But for the most part newspapers have been content to record its outbreak, to enumerate the head of cattle destroyed, and to estimate periodically the cost of this scourge to the country. There has been no great campaign against official methods, no general demand that the scientific resources of the country should be mobilised to stamp out what is a very serious state of affairs. For this respite the Ministry of Agriculture may be thankful, for there seems a likelihood that when the public begin to inquire what steps are being taken to study the disease scientifically, some progress will already have been made. A long step in the right direction was taken when the official ban against the private study of foot-and-mouth disease was raised to a limited degree, and one of the first results of this more liberal policy appears in the December number of the *Journal of Comparative Pathology and Therapeutics*, where Dr. J. H. Arkwright, Dr. M. Burbury, Dr. S. P. Bedson, and Dr. H. B. Maitland record the results of work carried out by them at the Lister Institute.

The report is divided into two sections. The first section deals with the transmission of foot-and-mouth disease to rodents. The authors have confirmed the observations of continental workers that this disease can be easily and regularly transmitted to guinea-pigs, and have studied the main features of the disease in these animals in some detail. Transmission is usually effected by intracutaneous inoculation of the sole of the hind foot with diluted vesicle fluid, but intramuscular, subcutaneous, intracardiac, and intraperitoneal inoculations are also successful. The virus is also contained in the epithelium covering the vesicles—indeed, this was the source of the viruses used in these investigations; and the blood of animals in the early stages of the disease, as well as the oral secretions, are also infective. In guinea-pigs manifestations of the disease and the resulting immunity appear to be sufficiently clear-cut to make these animals reliable indicators of the presence or absence of an active virus, a matter of the first importance in the study of filterable viruses. Attempts to transmit the disease to rats and mice have been less successful, and it seems probable that the guinea-pig will remain the experimental animal of choice. Certain results which have been obtained in these investigations are rather startling in view of the extreme infectivity of the disease as it occurs among stock. No instance of spontaneous transmission from an infected to a susceptible guinea-pig was observed, though every opportunity was given for such a spread to take place. And though the blood of infected guinea-pigs contains the virus at certain periods of the disease, transmission by bugs from one animal to another has not been achieved. The second section of the paper contains a detailed account of the investigation made on the virus itself; all attempts at its cultivation have so far failed, and the authors find in their work confirmation of the unfavourable report of the recent German commission on the claims of Frosch and Dahmen to have succeeded in this matter. Many interesting observations have been made, however, on the survival of the virus in vitro under various conditions. It is found that survival is best at low temperatures, but in certain media it remains active at 37° C. for several days, and it is reasonably suggested that a careful study of these media may successfully pave the way to cultivation. The reaction of the medium appears to be of the highest importance, the optimum pH being 7·5–7·6, but, on the other hand, the virus seems to have a considerable degree of resistance to such agents as phenol, alcohol, and chloroform. Vesicle fluid, diluted 1 in 50 with saline, was shaken with chloroform in a stoppered bottle and then allowed to stand at room temperature in the dark for 176 hours, when it was still found to be infective.

The observations here briefly referred to appear to be of great interest and importance; the investigation is being carried out in a manner which augurs well for success, and it is not unreasonable to hope that a reproach to scientific medicine, by no means in this country alone, may soon cease to be justified.

◆

## THE NATURE OF MIGRAINE.

THE paroxysmal nervous headache known as migraine or "sick headache" is one of the most widespread and familiar of minor ailments. It is responsible for a great deal of suffering and loss of time, for it completely incapacitates its victims for periods varying from one to three days and is extremely painful. Probably because it is never fatal it has no known pathology, and practitioners who encounter it are reduced to tiding it over with palliatives and reassurance. To realise how vague an entity it is one has only to turn to a first-class work of reference. Osler mentions four out of the many theories of its causation: first, that it is a symptom of a toxæmia caused by bowel indigestion, uric acid, or some self-manufactured poison; secondly, that it is a vasomotor affection; thirdly, it is caused by the reflex action of some irritation such as a refractive error or troubles in the nose or sexual organs; fourthly, that it is due to a transient plugging of the foramen of Monro with increased pressure in the ventricles. It appears early in life and its attacks are precipitated by powerful emotion, fatigue of mind or body, digestive disturbances, or the ingestion of some particular kind of food. It has a fairly definite syndrome, and its premonitory signs are well marked; the patient sees apparitions of mice or dogs, or suffers from hemianopia or scotoma. Sometimes the hallucination takes the form of a fortification, brilliantly illuminated and coloured, and sometimes simply of zigzag lines or balls of light. Numbness, cramp, and psychic disturbances also accompany it. The headache begins as a localised spot on the temple, forehead, or eyeball, and spreads over one side of the head and sometimes to the neck and arm. It is generally unilateral, but may affect both sides. Vomiting is common and often gives relief. A recent German publication[1] includes it in the same classification with a group of conditions which, though they differ widely in their appearance, nevertheless have a great deal in common. Under the heading of "exudative paroxysms" are gathered together Czerny's diathesis, Quincke's œdema, brain œdemata, acute œdema of the mucous membranes, urticaria, asthma, epilepsy, colica mucosa, and dysmenorrhœa. While most of these, if not all, can be caused by organic brain lesions and toxæmias, such as those that attend diabetes and nephritis, their syndromes in a large number of the patients seem to be "idiopathic"—*i.e.*, they exist because of some unknown constitutional peculiarity. This predisposition is often inherited, and the sufferers nearly all have a personal or family history of mental or nervous disorder of some kind, but a large proportion are almost certainly due to sensitivity to foreign proteins, and it may be that where no neuropathic history is discoverable the patient will be found to have developed an anaphylaxis to one or more common proteins early in life. Sir Maurice Craig,[2] in a paper on the importance of protein hypersensitivity in a special group of epileptics, mentions that this is the cause of much migraine, and his skin-tests, which proved so valuable in detecting the offending proteins in epileptics, have been successfully applied to patients of the minor condition. Both ailments have disappeared when the offending substance was removed from the diet. As might be expected, migraine is common in conjunction with other complaints of this group. Vining[3] and others have written on migraine in combination with epilepsy, and Flatau[4] has declined to regard it as an entity, but holds that it is a symptom-complex that is only developed from a gouty diathesis. Dr. Bolten agrees with this view to the extent that he will not limit the causation to gout, but maintains that the reaction may occur in any neuro-toxic diathesis. He states that one of the symptoms of "genuine" migraine is always an œdema of the skin, as well as œdema of the cerebral membrane (probably also of the ependyma and tela chorioidea) and the lining of the stomach. The root-cause is some deficiency in the accelerating secretions, which gives the other normal secretions a toxic effect. The vasomotor paroxysm is a defence-mechanism to get rid of these toxins, which are excreted into the skin and mucous membranes and finally vomited or sweated. Nevertheless it hardly seems just to draw a hard-and-fast line between the migraine that has its origin in endocrine disturbance and the vasomotor reaction that is caused by reflex stimulation, exogenous toxæmia, emotional disturbance, fatigue or protein sensitivity, where there is no œdema and where the endocrine disturbance is probably a symptom and not a cause. It appears more likely that the headache and vomiting are, like epilepsy and other conditions, a reflex nervous reaction that can be produced by any cause that stimulates the sympathetic centres, whether toxic, nervous, or psychic.

"Ne quid nimis."

## THE NURSING SERVICE IN MENTAL HOSPITALS.

THE Board of Control has had under consideration the Report of the Departmental Committee on Nursing together with the report of the proceedings of a conference which took place in London last April when the nursing service in mental hospitals was under discussion. Both the documents deserve serious attention, and the Board of Control has addressed a circular letter upon them to the visiting committees of every county and borough mental hospital in England and Wales. The desire of the Board is to raise the status of the nursing service in mental hospitals upon some uniform plan. At the present time many mental hospitals have difficulty in attracting and in retaining suitable women nurses, and improvements in the nursing service should obviously be general and in accordance with a definite plan if the service as a whole is to be raised. The Board feels that when it becomes known that all progressive visiting committees of mental institutions are recognising the necessity of making the nursing service a more attractive career for men and for women, the difficulties of recruiting for the service should disappear. The recommendations made by the Board in its circular letter begin with an alteration in the nomenclature of the staffs, which has the advantage of defining the duties of the nurses in each grade of either sex, this making it easier to understand why in certain circumstances it is preferable that the nurses should have been certificated or registered in both general and mental nursing. The facilities for giving to men a general hospital training are as yet very imperfect, so that it is a counsel of perfection that only doubly trained male nurses shall be available for the higher positions in the service, but efforts, which will be welcomed by the Board, might well be made to induce general hospitals to accept men as probationers for training in general nursing. The suitable arrangements ought not to be hard to come by. Further recommendations on the part of the Board of Control emphasise the necessity of better remuneration and living accommodation in the service, and for further organisation to provide occupations and recreation. On the difficult subject of the nursing of male patients by women nurses the Board states definitely that there are many male patients who can be nursed by women nurses with great advantage, agreeing here with the Report of the Departmental Committee, which advocated a wider extension of the practice.

## ECTOSCOPY.

IT is, of course, well known that a sudden cough leads to a slight temporary bulging of the intercostal spaces and a sudden inspiration to a slight temporary retraction. Dr. Eduard Weisz has studied this phenomenon in detail, and has found that slight temporary muscular movements produced by the same means are noticeable in regions that are at a distance from the chest, such as the abdomen and the back. An account of his work appears in another column of this issue. The best method of obtaining the movements is to get the subject to say suddenly the word "kitt"—the so-called speech phenomenon; but a sudden inspiratory sniff through the nose is also effective. Movements are best observed with the patient standing in a room with darkened walls and the light coming in from one side. Dr. Weisz has pointed out that the movements in the intercostal spaces occur at the borders of the lungs and they afford the best means clinically of determining the position of the base of the lung. This method of examination may be of real value in determining the presence of fluid in the thorax, when the chest is dull to percussion, since the speech phenomenon is particularly evident under these conditions. In fact, the bulging of the intercostal spaces will coincide with the lower level of the fluid, and if experience bears this out, this will be the only method we possess of separating the dull area due to fluid from the liver or spleen beneath. Dr. Weisz also claims to distinguish between organic and functional disease of the abdomen, since his method is another way of determining the alteration in tone of the muscles overlying an abnormally affected viscus, an alteration which is ordinarily determined by palpation when a sense of rigidity is experienced. But a warning is necessary here. It is probable that such a means of investigation indicates an abnormal condition of the viscus, but not whether this condition is produced by organic disease, since the viscus which produces the symptoms may react in the same manner both from functional and organic disease. The method may be regarded as a worthy addition to the procedures of clinical investigation, and it has already received considerable attention on the continent, especially in Germany.

## THE EARLY HISTORY OF AERONAUTICS.

THE Royal Society of Medicine held another successful social evening on Feb. 1st, when Dr. F. J. Poynton gave an address on the Part Taken by Doctors in the Early Days of Aeronautics. He traced men's interest in aerial flight back to the earliest recorded times. In the "Book of the Dead," he pointed out, the spirits were shown winged, and there were many stories of men aspiring to the sky drawn by eagles or with wings. The earliest illustration was found in a wood-cut of Dædalus and Icarus, published in 1493. Turning to the particular history of the lighter-than-air machine, the lecturer drew attention to the many celebrated names associated with it. Roger Bacon, Montanus, Leonardo da Vinci, Robert Hook, Cavarro, Swedenborg, Lavoisier, and Priestley had all been bitten by the craze, but, as so often happened, the solution of the problem came from an unexpected source. In 1782 the two brothers Montgolfier first saw a paper sphere filled with heated air float to the ceiling of their room. They gave their first public demonstration in the following year, when a sphere with a capacity of 65 cubic feet was successfully floated with heated air. The importance of their success was realised at once. Two and a half months later hydrogen was first used by Mr. Charles to inflate a balloon of such dimensions that 1125 lb. of iron and 560 lb. of sulphuric acid were required to supply it. Fierce controversy ensued as to which of the two methods was the better. Later, in 1783, a cage-balloon carrying a sheep, a duck, and a cock was sent up in the presence of the King, the Queen (Marie Antoinette), and a large and distinguished crowd. Among them were Marat, who was very interested in aeronautics; Mr. Charles, who was afterwards saved from the guillotine by his eloquent address to the crowd, in which he recalled his aerial experiments and the popular enthusiasm they aroused; and the famous de Rozier, who began life as a medical student at Metz, but turned to science to escape the ordeal of anatomy. He became director of the first science museum in Paris, and in 1783 made an aerial journey across Paris. Benjamin Franklin was the link between these Parisian ventures and England, through his correspondence with Sir Joseph Banks, in the course of which he wrote: "Your philosophy *seems to be too bashful; in this* country we are not so ashamed of being laughed at." But it was not long before the "balloon madness" of Paris, with its caricatures, toy balloons, stamped handkerchiefs, and even garters, spread to London, and in September, 1783, a balloon was sent up from the Artillery Ground. On Feb. 2nd, 1784, a 5-foot balloon let free at Sandwich floated across to Flanders, and was the first to cross the Channel. In Scotland the versatile and ill-fated Dr. Tytler made an ascent in a hot-air balloon on August 25th, but returned to earth with some precipitancy. His later attempts failed. In 1784 the Italian Lunardi arrived in London with letters of introduction to Banks and others, and in September made an ascent in a gas balloon which was filled for the occasion by Dr. George Fordyce, of St. Thomas's Hospital. Among the spectators on that occasion were Mr. John Sheldon, F.R.S., of Paris, surgeon to the Westminster Infirmary; Dr. Jeffries, a Boston physician practising in London; and the Frenchman, Blanchard. These three were the pioneers of early English attempts to fly. The first *woman to make an aerial journey* was Lunardi's friend, Mrs. Sage. On both sides of the Channel feverish preparations were being made to cross the water, and after several difficulties Blanchard and Jeffries succeeded in doing so on Jan. 7th, 1785, after a journey of 2 hours and 17 minutes. de Rozier's effort from Boulogne resulted in the balloon crashing on French soil and killing both him and his companion, de Romain. Dr. Poynton illustrated his lecture by a large series of rare prints and contemporary documents.

## A DIAGNOSTIC SKIN REACTION FOR TYPHOID.

THE early course of typhoid fever rarely proceeds according to plan and there are many conditions which resemble it closely enough to give rise to anxiety. A reliable test which would exclude typhoid during the first few days of a febrile disease would be distinctly helpful in practice. Dr. G. Rodriguez, of Buenos Aires, has experimented on a skin reaction for typhoid which is analogous to the Schick and Dick reactions. He used Vincent's vaccine in doses of 100,000 bacilli in a volume of 0·1 c.cm., injected intradermally, and classified the reactions as weak, true, and strong, according to whether the result was a macule, a slight papule, or a large papule with tumescence. A series of 20 cases of typhoid and other diseases was tried with this dose, but the results suggested that it was too small, and Dr. Rodriguez increased it to 2 millions (in 0·1 c.cm.) for the next group of patients. Altogether the test was tried in 39 cases, of which 26 were typhoid in various stages, 4 were paratyphoid, and 9 were other febrile or bowel conditions. Of the typhoid cases 13 gave positive reactions, 12 negative, and 1 doubtful. All the remainder gave negative reactions. He concludes that early cases of typhoid give a positive reaction, which becomes negative again in convalescence, but not in the presence of a complication or relapse. Dr. Rodriguez quotes a paper by S. Costa, L. Boyer, and E. Giraud, who investigated a skin reaction produced by the filtrate of broth cultures filtered through a Chamberland candle. They found a negative reaction in 15 cases of typhoid fever, but 12 convalescent or cured cases gave a positive reaction. One normal individual and 11 with diseases other than typhoid also gave a positive reaction. Rodriguez attempted to repeat this work, but obtained only doubtful results.

## VOLUNTARY HOSPITAL DEVELOPMENTS.

THE fourth report of the Somerset Voluntary Hospitals Committee, under the Voluntary Hospitals Commission, has just been issued, and justifies its affirmation of the new hold now obtained by the voluntary system on public sentiment. There is no doubt that during the last five years a real change of public opinion has occurred. The advantages of the voluntary system have become more widely *appreciated, while its defects are being* removed and some of its financial problems are being solved, and it is the public, of course, who is supplying the solutions. The appointment of the Voluntary Hospitals Commission with local committees in every county and borough was a definite admission, or rather statement, that the public is intimately interested in the existence of the voluntary hospitals. When, some four years ago, Parliament voted £500,000 to meet the urgent plight in which some of these institutions found themselves, it followed that financial records, kept in accordance with some definite plan, became due to the community. The system of presentation of annual accounts in accordance with a uniform system has now been largely adopted, with the result that all who study the reports of their County Committee can understand what their own hospitals are doing for them, where the needs lie, and what claims there are upon individual or organised generosity. All classes have assisted in the financial recovery of the hospitals which has been a marked feature of the position since 1921, and the issue of such documents as the one before us will keep the general enthusiasm alive.

An important matter which the hospitals have recently been asked to consider is the institution of a general pension scheme for nurses. In February, 1923, the College of Nursing put forward a tentative scheme of universal application to all nurses in all forms of employment. Early in 1925 a Conference on Pensions for Hospital Officers and Nurses was convened by King Edward's Fund, and a scheme, which was prepared by a small committee of members invited to that Conference, has been circulated for the opinions of the voluntary hospitals. No recommendations were appended to the scheme; the difficulties ahead require deliberation. The last report of the Director of Hospital Services, Joint Council of the Order of St. John, and the British Red Cross Society, includes an article by Mr. H. N. Crouch, chairman of the Somerset Committee, in which the problem is set out with suggestions for its solution.

## OSMOTIC THERAPY IN GLAUCOMA.

Two articles in the January number of the *British Journal of Ophthalmology* by W. S. Duke-Elder throw new light on the pathology of glaucoma and point to a new direction in which the treatment of that disease is likely to develop. Further advances in ophthalmology, said Sir John Parsons in his Bowman lecture for 1925, will not be along the lines of improvement or elaboration of operative technique, but rather by a fuller understanding of the biochemistry of the eye and of the physiology of vision. Mr. Duke-Elder's contribution to this advance consists in the first place of an experimental investigation into the reaction of the intraocular pressure to osmotic variation in the blood, and in the second place of a record of the results of the clinical application of knowledge so gained in the treatment of four cases of glaucoma. The mass of the experimental work on intraocular pressure that has been done hitherto has been chiefly concerned with its relation to the general blood pressure, but although the blood pressure in the veins of the retina must obviously constitute a limit higher than which the intraocular pressure cannot rise without causing their collapse, investigation has entirely failed to establish any constant relation between the two. No doubt the energy necessary for the maintenance of the intraocular pressure is derived from the blood stream, but in considering this, to quote Mr. Duke-Elder, "in addition to the external dynamic energy of the blood in mass movement, which is measured as blood pressure, we must also take into account the internal kinetic energy of the blood in molecular movement, which is measured as osmotic pressure." To test this a series of experiments were performed on anæsthetised cats, the technique of which is fully explained. The main results of these experiments go to prove that the introduction of hypotonic saline solution into the blood is followed by a rise in intraocular pressure which lasts for some hours, while conversely the introduction of hypertonic solutions is followed by a corresponding fall in the intraocular pressure. In recording these experiments full credit is given to previous experimenters, of whose writings a considerable bibliography is appended. Indeed, one observer, E. Hertel, experimenting on rabbits, appears to have anticipated Duke-Elder's results. The clinical application of the knowledge so gained is already of much practical interest. A 30 per cent.—i.e., nearly saturated—solution of common salt was used. About 50 c.cm. of this solution injected slowly and evenly over a period of ten minutes into a vein is quite safe, and produces no discomfort except thirst (which must not be relieved). In the four patients so treated the intraocular tension was materially reduced, the effect lasting for several hours. Thus valuable time can be gained and operative measures performed under the best conditions. This is about as far as the practical application of the new treatment has gone at present. Whether or not more permanent benefit can be derived from it is a problem for the future.

## CALCIUM DEFICIENCY AND WHOOPING-COUGH.

IT might be thought comparatively easy to estimate the various inorganic constituents of the blood; but they are present in such small amounts that until recent years their estimation has been attended by some difficulty, unless fairly liberal quantities of blood are available. Now, however, with the advance of biochemical methods, such constituents as calcium and phosphorus can be readily determined on a few cubic centimetres of blood. Such routine determinations have considerably clarified our conceptions of rickets, and along with radiographic control they have given precision to ultra-violet light treatment. Already determinations of blood calcium in other conditions are beginning to yield results, and this is strikingly illustrated by two references to recent literature on subjects so far apart as whooping-cough in infants and milk fever in cows. G. F. Powers, in the *American Journal of Diseases of Children* for November, describes five cases of whooping-cough in children under 17 months in all of which the blood calcium was below normal (10 mg. per 100 c.cm. of blood); in one of them it was as low as 4·0 mg. This suggests that the convulsive spasms of pertussis are related to tetany, in which there is a diminution in the blood calcium, and it is possible that in pertussis characterised by marked convulsions the administration of calcium might be useful. The possibility of benefit being derived from light treatment also suggests itself. In milk fever in cows, Little and Wright[1] have recently demonstrated that the blood calcium is definitely subnormal. In mild cases they found a drop of from 20 to 30 per cent. at the onset of the disease, and in severe cases the drop was as much as 60 per cent. This is one of the first well-attested facts in the pathology of a condition which has given rise to much controversy, and the findings are of interest in view of the suggestion put forward by Dryerre and Greig,[2] that milk fever is due to a relative deficiency in the parathyroids which gives rise to guanidine intoxication. While a lowered blood calcium does not necessarily imply a parathyroid deficiency the correlation of the two conditions is sufficiently marked to warrant research along the lines of the suggested endocrine upset. It seems probable that similar investigations in other diseases will reveal further disordered mineral balances in the blood.

## THE INSTINCT OF SPEECH.

IN a recent number of the *British Journal of Psychology* (1925, xvi., 53) appeared a short paper by Dr. J. W. Tomb on the Intuitive Capacity of Children to Understand Spoken Language. The paper gives a summary of his observations of young children of English parentage born in India who, before the age of 18 months, are found able to understand and follow the directions of their parents in English, their ayahs in Bengali, and the house-servants in Hindustani, and who also at 3 and 4 years of age can converse freely with these different groups in their own tongues. The parents, on the contrary, with much labour and the aid of a teacher, may have acquired no more than is requisite to communicate necessary orders to the ayahs and house-servants, and do so often in disconnected words, unlike the children who speak in sentences. Dr. Tomb's observations are of much interest, but the inferences from his observations, on which he invites criticism, are open to question. "It is obvious," he says, "that a child's capacity for learning languages does not depend on intelligence, for if this were the case it is reasonable to assume that the parents would pick up the various vernaculars more quickly than their children." Most psychologists would grant that the linguistic capacity is not dependent on "general intelligence" alone, but is partly a "specific" innate capacity of the mind. Speech itself is an inborn instinct which, like all other instincts, lives by what it feeds upon and has its period of maximum activity during the early years of life. If no food be provided in the form of audible speech, as in the case of the child born deaf, the result is the deaf-mute. If, on the other hand, three or four languages be audible, all will be assimilated with equal ease, particularly during the early years. Let the admission of the deaf-mute into the deaf school be delayed until the age of (say) 10 or 12, and his acquirement of speech will be difficult, because of the weakening of the instinct from lack of use. In a similar way the Englishman transferred to India after attaining maturity has relative difficulty in understanding and acquiring facility in the native dialects. It is not, then, so much a matter of intelligence as of the functioning of an instinct, and Dr. Tomb's observations are confirmatory of what was previously known. The further inference made that a child must have a capacity for "intuitively placing the correct meaning on spoken sounds" is, we think, more than the facts justify. Meaning is indicated or suggested to the child in some manner other than speech, but he must obviously have the capacity to grasp and remember the association.

## SURGICAL EXAMINATIONS.

THE qualifications demanded of a surgeon are many and exacting. Essentially he must have manual dexterity of a high order and his judgment must be sound; whilst a wisdom which comprehends more than the knowledge of his actual craft is almost a necessary asset. The evolutionary changes of late years have made him more and more independent of his medical colleague. The days have gone when the physician's advice as to the time and nature of an intervention in acute abdominal disease was sought as a matter of course. The vivid pictures of the operating-table have transformed the surgeon into a clinician whose pre-operative opinion has become of unassailable value. Whether it be in the realms of neurology or of diseases of the abdomen or chest, we see this change occurring, and perhaps a new generation of specialists will arise who will treat indiscriminately the medical and surgical diseases of the particular system of the body to which they have given their attention. At present the qualifications of the aspirant to surgery are tested by examinations which are chiefly calculated to reveal his clinical knowledge; and this they do with efficiency. His technical ability remains a closed book to the examiner. Yet how important manual dexterity is in surgery; every incision made is an irrevocable step taken, after which, however skilfully performed, there can be no absolute restitution to the status quo ante. Save in the case of nerves repair takes place solely by scar-tissue formation, and the body can never again be quite so perfect as it was before the surgeon's intervention. Sometimes the deviation from normal is so slight that it is not, or cannot be, noticed by the patient, and naturally this ideal is more often reached by the superlatively skilled than by the occasional operator. The remembrance of this fact indicates how essential it is to ensure reasonable technical ability in all those upon whom diplomas in surgery are conferred. To prevent that licensing of the incompetent, of which he recently complained,[1] Sir John O'Conor sends us a suggestion that "every candidate for any surgical diploma shall present full notes of cases with complete details ('steps') of ten major operations, on the living subject, performed by himself—each record to be signed by the surgeon (teacher) who *personally* directed and assisted him in each operation." As examples of those which he includes in the category of major operations Sir John O'Conor mentions those performed for septic fractures, arthrotomy, varicose veins, hydrocele, hæmorrhoids, empyema, urinary extravasation, septic endometritis, and incomplete abortion. The principle is good, for too much care cannot be taken to render men proficient who propose to practise surgery. An alternative system might require candidates to have held an appointment equivalent to that of a first assistant in a continental clinic for a definite period longer than the usual tenure of office of house surgeons in this country. It is an undisputed fact that much experience and knowledge of technique can be acquired by close association with a master surgeon, and if the candidate were required to have performed operations assisted by his teacher all reasonable steps would have been taken to render him proficient. There are, however, difficulties in carrying out such suggestions with our present system of medical education.

## CANCER IN RELATION TO OCCUPATION.

AN investigation into the Statistics of Cancer in Different Trades and Professions by Dr. Matthew Young and Mr. W. T. Russell, with the collaboration of Dr. John Brownlee and Dr. E. L. Collis[1] has just been published as a green book (Special Report Series No. 99) by the Medical Research Council. The work has been made possible by the courtesy of the Registrar-General in affording facilities of access to certain documents in his possession. These included cards on which were coded the sex, age, specific trade, and cause of death of men who died in 1910, 1911, and 1912. On 46,118 cards which recorded deaths from malignant disease the site of the tumour was for the most part noted, and it has thus been possible to make a detailed survey of the relation of cancer to occupation. A brief introduction is followed by a discussion of previously published data. The methods of analysis used in this investigation are then set out. There follow sections on the incidence of cancer in the principal sites in different occupations, and on the relationship between different types of cancer, between cancer in different sites and syphilis, and between cancer and chronic alcoholism. The conclusions of the investigation are then briefly summarised. The close association of some types of cancer with exposure to particular risks—for example, chimney-sweeps' cancer and mule-spinners' cancer—has been confirmed, but no conclusive evidence has been obtained of such a connexion between the nature of the employment and other forms of cancer, notably internal forms. In some occupations excessive smoking and drinking, which is permitted or facilitated by the nature of the occupation, appears to be the important predisposing factor and not anything inherent in the employment itself, while the incidence of syphilis in different occupational groups seems to have some association with that of lingual cancer. With the main conclusion that occupational risk is only one of several predisposing causes of cancer in different instances and under different circumstances all are likely to agree.

It was hoped that such an examination might give further information as to the wide influence of substances already recognised as harmful, or might even disclose other injurious substances. But the difficulty of interpreting the material has proved very great, and the result of a praiseworthy and laborious effort appears on the whole to be disappointing. In many trades or occupations the number employed is small and consequently the number of deaths is liable to considerable random error. Again, as is made clear in the foreword to the report, statistical science is still in a developmental stage, and there exists difference of opinion between persons equally competent to judge as to the applicability of particular methods of comparing figures. For example, the strong preference expressed by the authors for the use of the so-called life table death-rates over standardised death-rates is not shared by some of their colleagues, and there are other technical points over which experts are not yet in agreement. The use of the method of proportional mortality has the disadvantage that the proportion of cancer of any particular site in one occupational group may be high simply because within that group the rate of mortality from cancer of another site is low, and the majority of the Statistical Committee of the Council are of opinion that conclusions based upon this method and unconfirmed or incapable of confirmation by a study of the site rates themselves should be accepted with reserve. However, sufficient material is provided in the tabular matter of this report, and in data previously published, to permit other investigators to try and elucidate this complex subject by pursuing research on different lines.

---

## MEDICAL PRACTICE IN CHINA.

THE status of qualified medical men in China, whether missionaries or otherwise, is likely to be very uncertain if the rights which they have enjoyed as foreigners should be abolished. At present no protection is afforded them comparable to that which the profession has in England, America, and elsewhere. If a doctor in China has no status from a treaty he may be sued in a Chinese court and have to meet very heavy claims for damages, as was illustrated quite recently when a German doctor lost a patient after an operation and had to pay $3000 damages. The Chinese custom of paying the doctor as long as the family is in health need not complicate the situation, for after all it is but an illustration of contract practice, but the immediate difficulty is that there is no sort of medical registration. People with the most rudimentary knowledge—embryonic medical students or even hospital coolies—frequently set up in practice on their own, and such organisations as the China Medical Association and the China Medical Missionary Association are quite unable to control the unqualified practitioners. If no protection for medical men is arranged at the Extra-Territorial Conference their work in the future will be carried on with great risk and difficulty. If failure leads to financial disaster it may be supposed that only simple cases will be undertaken. There is little reason to think, however, that the Chinese Government would not welcome, in the interests of the medical profession among its own nationals, the setting up of a register of properly qualified medical men. Perhaps the plan followed by the Japanese when they took over Korea may be adopted. At first they had to recognise the existing native practitioners and doctors holding British degrees (these are still recognised). Only a five years' recognition within a limited area was granted to a large number of American doctors, but after the matter had been taken up diplomatically those who were already at work in Korea were given full permission to practise. Since then every newcomer from America has had to take a Japanese medical examination, and though an elaborate system of certificates and reports has been instituted and doctors are constantly under inspection, the net result, it is said, has been to the advantage of medical standards.

---

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—A post-graduate course started on Feb. 1st and will go on until March 20th. It includes demonstrations in the out-patient clinic on Monday, Tuesday, Thursday, and Friday afternoons, and a series of lectures by Dr. J. G. Greenfield, on the Pathology of the Nervous System, on Mondays at noon. If there are enough applicants there will also be lectures on the anatomy and physiology of the nervous system and clinical demonstrations on methods of examination. Further particulars may be had from the Dean of the Medical School of the Hospital, Queen-square, Bloomsbury, London, W.C. 1.

# Modern Technique in Treatment.

## CLIX.

## TREATMENT OF HYSTERICAL DISORDERS IN CHILDREN.

HYSTERICAL disorders below the age of puberty are not common, but do occur more frequently, even in quite young children, than is often supposed. Methods of treatment directed towards the immediate disabilities or symptoms of hysteria seldom fail. Greater difficulty is experienced in preparing against their recurrence. The hysterical temperament, when present, is inherent, not acquired, and, as Charcot says, "once hysterical, always liable to hysteria."

Hysteria is a condition difficult to define satisfactorily owing to the diversity of its symptoms, and to the lack of any known anatomical lesions on which to base its pathology. Definitions have been advanced by physiologists and psychologists, many of which are adequate up to a point, but none are sufficiently comprehensive to be entirely convincing. At the present day hysteria is generally considered to be a purely psychical disorder. The views of Babinski, Janet, and Freud are well known and need not be set out here. There are at least two outstanding features in the composition of hysterical subjects—namely, the presence of a neurotic temperament, with want of emotional balance and control of the will, and an unstable condition of the sympathetic nervous system. These are really the sources from which hysterical disorders spring. Evidence of sympathetic vaso-motor instability is more readily seen in the adult in such symptoms as flushings, faintings due to abdominal vascular distension with cerebral anæmia, and coldness and cyanosis of the extremities affected by hysterical palsies, often associated with absence of bleeding on pin-prick. Savill was the first to emphasise the importance of the rôle played by the sympathetic nervous system in hysteria, and even went so far as to state that most of the motor disorders of hysteria might be accounted for by local disturbances of the cerebral circulation. He was much impressed by the similarity of many hysterical motor disorders to those produced by definite vascular lesions in the brain. The continuation of the symptoms in the hysterical cases for indefinite periods after the supposed vascular disturbance he attributed to the psychical state of the patient. Although it is hardly possible to agree with all of his hypotheses, yet his theory of hysteria is decidedly attractive by reason of the effort made to formulate a pathological basis.

### *Hysterical Manifestations in Childhood.*

The commonest hysterical disorders in childhood are related to the motor system, and consist of paraplegias and monoplegias. Both spastic and flaccid types occur, but the loss of power is seldom complete, and shows variations in degree from day to day. In the spastic form, which is the commonest, some degree of flexion spasm or contraction is often present at the joints, and severe pain is usually complained of. Hysterical pain and spasm localised to a single joint, usually the hip, is sometimes observed, and may simulate very closely organic hip-joint disease. Spinal rigidity resembling caries is another hysterical manifestation sometimes met with in children. That curious condition known as astasia-abasia, in which the patient can scarcely stand or walk, and yet is able to perform all movements of the legs voluntarily when lying in bed, may also be observed. Sensory manifestations by themselves are exceedingly rare, but may be present in association with paralysis, and usually assume the stocking and glove distribution of anæsthesia, with a definite upper level which is characteristic of their hysterical nature. Other manifestations which may arise are hysterical dysphagia, aphonia, and hysterical vomiting. Mutism, defects of vision, ptosis or spasm of the orbiculares palpebrarum, tremors and convulsions of hysterical origin are very rarely met with before puberty.

### *Ætiology and Diagnosis.*

Evidence of neuropathy is nearly always traceable in the parentage of those who are the subjects of hysteria. The children of alcoholic parents are liable to be affected. The instability of the nervous system is inherited and permanent, but may be influenced by training. It is an interesting fact that before the advent of the secondary sex characteristics the disproportion between the sexes in the incidence of hysteria is very much smaller than after puberty. In fact, in childhood almost as many boys as girls are affected. Five years is roughly the earliest age at which hysterical disorders may be observed.

In hysteria the necessity of the diagnosis being correct is of the utmost importance. The most likely diseases in childhood to be confounded with hysteria are poliomyelitis, early spinal caries, and organic disease of the joints; disseminated sclerosis can fortunately be excluded at this period. It is well to remember that most hysterical disorders in children arise in association with some slight trauma which has caused local pain, or may even be superimposed upon some organic lesion in its early stages, such as tuberculous disease of bone. Other cases seem to be occasioned by purely psychic causes, such as shock and grief, or a child may by a process of subconscious imitation develop the infirmities of another individual with whom it has been in close contact. Stigmata of hysteria, such as hysterogenic zones, globus hystericus, flushings and faintings, which are an aid in diagnosis among adult patients, are very rarely observed in childhood. Numerous children are of the emotional or "nervous" type, but those which are liable to hysterical manifestations present no hall-mark by which to distinguish them.

### *Treatment.*

An essential feature in the treatment of the hysterical child is to recognise the type of mother one has to deal with. Very often she is highly neurotic and unwittingly does her best to foster the "functional" defect from which her child is suffering. Separation from home influences is always desirable, and is more easily obtained among patients of the hospital class. Gentle but firm persuasion that the loss of function will soon disappear will effect recovery in most cases. Massage, passive manipulations, and the faradic current are useful accessory aids. Many cases make a sudden and spontaneous recovery, especially when the patient has been placed in new surroundings. In overcoming contractures splints are to be avoided, as their presence only exaggerates the importance of the complaint in the patient's mind. Drugs are seldom necessary, but bromides and the tinctures of valerian and asafœtida may be employed in small doses, especially as they are antispasmodics and may possibly exercise a beneficial influence upon the unstable nervous system. The symptoms of hysteria are for the most part readily cured in children, as they are usually of a more simple character than those met with in the adult. Firmness, assurance of success, and the inspiring of confidence in the patient's mind are the most potent means the physician has in dispelling the manifestations of hysteria.

A word must be said on the question of the value of psycho-analysis as a form of treatment. While not denying that success may be achieved by this means in adolescent and adult patients, yet the employment of psycho-analysis in children is neither desirable nor necessary. The least contentious argument against its use is that the child's mind, and especially that of the hysterical child, is not sufficiently developed to reason formally.

The struggle, however, is not over when the hysterical paraplegia, let us say, has been overcome. An effort should be made to modify the routine of the child's daily life that recurrences may be avoided. A return to the home surroundings and over-zealous attentions of a neurotic parent will often lead to a renewal of hysterical symptoms. The nature of the trouble should be explained to the parents, and, if possible, their coöperation acquired with a view to avoiding an excess of attention being given to each childish complaint. Regular habits, open-air exercise, and the acquisition of interests or hobbies of a healthy nature should be encouraged. Excitements and over-fatigue should be shunned. The diet should be simple and liberal, and any physical ailments underlying the hysterical symptoms must receive attention. Trouble taken in training the child to keep its emotions within control and to exercise its will-power is well expended.

## PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

*(Continued from p. 1356, Dec. 26th, 1935.)*

### *Conclusion of Sir Walter Kinnear's Evidence.*

### (Q. 23648–23820.)

AMONGST other matters dealt with by Sir Walter Kinnear, Controller of the Insurance Department of the Ministry of Health, in the concluding part of his evidence was the question of continuing to give exempt persons medical benefit in return for the employers' contributions in respect of them. The witness said that he would regret to see such persons deprived of medical benefit, and he thought that employers would regard it as only right that their contributions should be applied in the interests of the health of their employees. He thought that the income limit for exempt persons who should be required to make their own arrangements for medical benefit should be raised from £160 to £250 so as to bring them into line with the limit adopted for voluntary contributors and with that for the exception of non-manual workers from insurance.

With regard to the additional benefits which societies can at present provide out of their surpluses and which are specified in the Act under 18 separate heads, Sir Walter Kinnear said that medical treatment for the dependants of the insured could not suitably be dealt with as an additional benefit, but should be faced as a problem affecting the whole insured population. He also suggested that certain other additional benefits, such as those which provide for the payment of pensions or superannuation allowances and the payment of contributions to superannuation funds, should be eliminated as being available to only a minority of the members of a society at the expense of the general body. Another suggestion supported by the witness was that if societies wanted to pay as an additional benefit sickness benefit from some date other than the fourth day (the normal date) they should only be allowed to do so as from the first day.

With regard to suggestions made to the Commission that payment of cash benefits should be made in cases of partial incapacity—e.g., to tuberculous persons capable of doing only part-work—the Controller drew a distinction between cases where such work was done as part of medical treatment in an institution and those cases where the person was working for an outside employer. As to the latter he said :—

---

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

> The test of partial incapacity (to be graded presumably according to the degree of incapacity) would involve rather serious administrative difficulties. So far as I can voice the mind of societies on the matter, I think societies would hesitate to undertake the task, and, indeed, I think it would be a very difficult provision to administer. On the whole, therefore, I am rather inclined to think, much as we may sympathise with the proposal, that it is scarcely one that should be adopted

### *Poor-law and other Local Medical Services.*

### (App. CIV. and Q. 21025–24245.)

Mr. A. B. Maclachlan and Mr H. W. S. Francis gave evidence on behalf of the Ministry of Health with regard to various health services other than the insurance medical services. Generally speaking, they said, the spheres of the insurance medical service and the maternity and child welfare service were mutually exclusive, and they indicated what was necessary to secure proper coördination between the two services There was overlapping between the Poor-law and other local services, both in the case of maternity and child welfare, and in regard to tuberculosis. The stigma supposed to attach to Poor-law treatment was steadily decreasing in force in every class of case. As to coöperation between general practitioners and tuberculosis officers, the witnesses said :—

> It is not claimed that fully satisfactory coördination has yet been attained in all parts of the country Much depends on the personality of the tuberculosis officer and his relations with the practitioners in the particular district, and there will probably always be opposition in some quarters to the use of set forms as a means of collaboration. There is evidence, however, that the respective functions of the tuberculosis dispensary and of the insurance practitioners are gradually coming to be better understood ; and that the dispensaries are tending to adhere more closely to their proper rôle as centres for consultation, expert examination, special treatment, &c.

On the question of destitute sick persons having free choice of doctor, the reply was that such a service would tend to be extremely costly ; it would be very difficult to limit the liability of the local authority to sick persons who were in fact destitute, and a service ought not to be provided at the public cost without public responsibility for its quality.

As to free choice generally in the case of a public medical service, it was said :—

> The principle of free choice would be retained under a capitation system and within limits it would be possible even with a salaried system in urban areas In many rural areas there is practically no free choice now, and the position would not be materially changed, whatever system was adopted, on the institution of a public medical service

On the subject of administration of unified medical services, the Ministry representatives said that the consultative council on local health administration had expressed strong opposition to the appointment of an ad hoc independent body for the purpose of administering health services. The council had recommended —

> (a) That the county borough councils should be the local health authorities for county boroughs and should be required to submit schemes to the Ministry of Health providing for the inclusion under one authority of all existing health services ; (b) that while it would be desirable to correlate all health services within the area of each administrative county, it would be undesirable that all health services within that area should be administered by one authority

### *Further Scottish Evidence.*

### (App. CV. and Q. 24210–24307.)

Sir James Leishman and Mr. G. W. Wight said that they were, in the main essentials, in agreement with the evidence given by the Ministry of Health representatives With regard to extended services, they thought that dental treatment and convalescent care could not at present be added because the funds available were not sufficient.

> We would very greatly value aids to diagnosis, second opinions, electrical treatment, massage and so on, and we would greatly value such a measure of finance as would enable us to help the voluntary hospitals in Scotland if they are to continue to be an integral part of the medical machine.

Discussion with surgeons and physicians had established the view that an extension of medical benefit was to be preferred immediately to dental treatment, the importance of which, however, was not minimised. The cost of the former on the lines indicated was about 3s per annum per insured person, but dental treatment would cost about 7s. 6d With regard to Poor-law beds, Sir James Leishman said that the handing over of these to the local authority would not, in Scotland, very materially lighten the burden, because there are far fewer beds than people think, and any excess may be in places where the beds are not wanted.

### *Sir William Glyn-Jones on the Future of Insurance Committees.*

### (Q 24308–21532 and App. CVI.)

Sir William Glyn Jones, who for many years was chairman of the Middlesex Insurance Committee and had also been chairman of the National Association of Insurance Committees, gave his opinion, which was opposed to that of the National Association, that while insurance committees fulfilled a very useful purpose in the initiation and early years of the insurance scheme, the time had now come when, owing to a variety of causes, their powers and duties should be transferred to the larger local authorities. He said that neither the arrangements with the doctors nor those with the pharmacists have ever been in the hands of the insurance committees. His view was that the administration of medical benefit had become almost entirely routine and office work, which, he said incidentally, was carried out most efficiently by the existing staff, who would undoubtedly have to be absorbed by any local authority taking over the arrangements. As regards the lack of material requiring the considered judgment of the Committee, the witness said that the average length of time of a committee meeting for the Middlesex Insurance Committee in the last two years would be about a quarter of an hour at each of the 12 meetings. He pointed out that the work in connexion with tuberculosis which was originally performed by insurance committees, and which did afford some opportunity for real exercise of judgment, had inevitably had to be handed over to the local health authority The question of transfer of functions of insurance committees fell, said the witness, within the second part of the Terms of Reference of the Royal Commission on Local Government, which is : "To investigate the relations between the several local authorities and generally to make recommendations as to their constitution, areas, and functions."

### *National Confederation of Employers' Organisations.*

### (Q. 21533–21813 and App. CVII.)

Mr J Forbes Watson and Mr J A. Gregorson gave evidence on behalf of this confederation, which, they said, represented the views of employers of about half the insured population. The purpose of their evidence was to show that the cost of the various social services was more than the industry of this country can continue to bear and immeasurably greater than that which the industry of any other country is called upon to bear ; that the existing cost of the health insurance service is out of perspective in relation to the cost of the other social services, that the existing system of health insurance is over-financed, and that an immediate and substantial reduction in the present rate of health insurance contributions can be effected while still retaining the system on an actuarial basis and providing the benefits which it contemplated. While concurring in the view that the money spent on health insurance improves the health of the worker, they thought it quite a matter of speculation whether the expenditure was repaid by the greater efficiency, wage-earning capacity, and general contentment of the workers. The first consideration was the fullest possible measure of employment, and if more money was being taken out of industry than was essential for the existing statutory benefits, the view of the employers was that this was harmful to industry and therefore to the workers. They were not prepared to say by exactly how much the contributions could be reduced, but thought that the Government actuary might be a little more optimistic in his views, and in any case they suggested that the burden would be more equitably distributed if the taxpayer paid a higher share, and the employer, as such, a smaller share as the counting of heads of the numbers employed did not give the most equitable distribution of the burden.

In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, 1925, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 451–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6); April 18th, p. 830; Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6); Evidence of the Insurance Committees (May 23rd, pp. 1097–8); Evidence of Various Approved Societies (May 30th, pp. 1135–6); Evidence of the British Medical Association (June 6th, pp. 1184–6; June 13th, pp. 1248–50; June 20th, pp. 1315–6); Evidence of other Medical Bodies (June 20th, p. 1316; June 27th, p. 1348); Individual Evidence (June 27th, p. 1348); Medical Services in the Factory, Ministry of Health Inquiry Room, Evidence of National Sailors' and Firemen's Union and of Loyal Order of Ancient Shepherds (July 4th, p. 36); Evidence of Friendly Societies' Medical Alliance, South Wales and Monmouthshire Alliance of Medical Aid Societies, Friendly Societies' Medical Officers' Union, Association of Approved Societies, Standing Committee of Scottish Insured Women, and Society of Medical Officers of Health (July 11th, pp. 86–8); Evidence of the British Hospitals Association, the Sheffield Joint Hospitals Council, and the Middlesex Hospital (July 25th, pp. 181–2); Evidence of Opticians' Associations (August 1st, pp. 224–6); Evidence of Council of British Ophthalmologists, of Ophthalmic Benefit Committee, of Chemists, and of Drug Store Proprietors (August 15th, pp. 348–50); Evidence of Chartered Society of Massage and Medical Gymnastics, of the Ivory Cross, of Scottish Panel Chemists, Practice among Highland Crofters, and of National Farmers' Union of Scotland (August 22nd, pp. 402–3); Evidence of Nursing and other Women's Organisations (Sept. 5th, pp. 519–20); Views of Trade-Unions, Evidence of Approved Societies (Sept. 19th, pp. 618–9); Evidence of Joint Tuberculosis Council, Cambridgeshire Tuberculosis After-Care Association, London County Council on Treatment of Tuberculosis, British Social Hygiene Council, and London Insurance Committee (Oct. 3rd, pp. 722–3); Evidence of Society of Apothecaries of London, East of Scotland Dentists' Panel, Association of Poor-law Unions, Association of Parish Councils of Scotland, and of Mr. W. J. Braithwaite (Oct. 17th, pp. 828–9); Evidence of National Council of Agriculture, as to Casual Employees of Councils and Delay in Paying Sickness Benefit, of National Insurance Audit Department, Chartered Accountants of Scotland, Department of Economics (Cambridge), the Actuarial Basis of the Act, and of the Government Actuary (Nov. 7th, pp. 985–7); Provision of Extended Medical and Allied Services, Specialist and Consultant Services, Treatment of Dependants, Income Limit of Manual Workers, and Hospital Provision (Nov. 28th, pp. 1123–4); Official Evidence (Dec. 12th, pp. 1247–8); Evidence as to Question of Proof of Unemployment, and of Sir Walter Kinnear (Dec. 26th, pp. 1355–6).

# THE GENERAL MEDICAL COUNCIL.

## MEMORANDUM AS TO THE CONSTITUTION, FUNCTIONS, AND PROCEDURE.

BY THE REGISTRAR.

THERE is so much misconception at the present moment in regard to the General Medical Council, not only amongst journalists and the public, but amongst members of the medical profession themselves, that it seems advisable to give accurate information on the subject, in order that it may be more widely known how the Council is composed, what are its duties, and how these are carried out. What follows may be found in the documents prefixed to the Medical Register, in the published minutes and standing orders of the Council, in the public addresses of the President, and in Harper's "Legal Decisions upon the Medical and Dentists Acts" (Constable and Co.).

### *Constitution.*

The Council was constituted under the Medical Act, 1858, and its composition was somewhat altered by the Act of 1886. It now consists of 18 members appointed by the universities in the United Kingdom having medical faculties; of 9 members appointed by the medical corporations, such as the Royal Colleges of Physicians and Surgeons; of 5 members appointed by His Majesty in Council; and of 6 members directly elected by members of the profession as a whole—a total of 38. To these are added 3 dentists who are members of the Dental Board and are appointed for dental business. The universities may appoint either medical men or laymen; generally it is not the medical faculty of the university that appoints the member, but the academic governing body, whatever that may be. In Cambridge, for example, he is elected by the members of the Senate, in the same way as the representatives in Parliament. The representatives of the medical corporations must be members of these bodies, and consequently must be registered practitioners. The representatives nominated by His Majesty in Council are generally appointed for special reasons, relating to departments of the public medical service. For instance, the chief medical officers of the public health departments in England, Scotland, and Ireland have been or are among them; the medical editor of the British Pharmacopœia, 1914, was recently appointed by the Crown with reference to his special knowledge of this department; for many years before the formation of the Dental Board, Sir Charles Tomes was appointed to represent dentistry; Sir Francis Champneys, the chairman of the Central Midwives' Board for England, was appointed soon after that body came into being, when the rules of the Board became subject to the approval of the Council; and so on. The direct representatives are practitioners elected, four from England, one from Scotland, and one from Ireland, by ballot of all the members of the profession having registered addresses in these countries respectively. The nominees of the Privy Council and the direct representatives of the profession are appointed for five years. The representatives of the universities and medical corporations may be appointed for five years or less.

It will thus be observed that the 18 members appointed by the universities, and the five members appointed by His Majesty in Council, may all be laymen; but so far no laymen have been appointed. As will be seen later, the functions of the Council are largely concerned with medical education, and consequently the universities have found it expedient to appoint members of their body conversant with this subject, and the Privy Council have found it desirable to appoint persons having special knowledge of certain subjects of public importance, which might not otherwise be represented.

It is important that the constitution of the Council should not vary too quickly, because the Council meets only twice a year, and its executive committee only three or four times It naturally takes some time for members to become acquainted with their duties Moreover, it is important that members should have some knowledge of precedents in regard *to education and to judicial decisions And again*, when applications are received from practitioners whose names have been erased from the Register for their restoration thereto, it is desirable that there should be members present who were in attendance when the case was originally heard, and therefore have the circumstances in their personal recollection.

### *Functions*

Sins of commission—more often *sins* of omission—are freely laid to the Council's account, of which, from its very nature and constitution, it cannot be otherwise than guiltless It is reprimanded for doing what the law says it *shall* do It is bitterly reproached for leaving *undone what the law gives it neither* power nor means to do It is spoken of at one time as the ' *Parliament of the profession,* ' yet it has no authority to legislate for anybody, and it cannot make even a by law for any but its own proceedings At another time it is scornfully described as a doctors' trade-union " , yet it cannot legally levy an annual subscription, *or say a word on the matter* of rates of pay, or hours of work, or disputes with employers, or theories of practice ; it offers no pecuniary benefits or strike-pay ; and it *can* be sued in the courts like any *other* corporation. It exists, in fact, for the protection of the public, not of the profession

The Council is, in fact, neither a parliament for making professional laws nor a union for protecting professional interests

When the Council was *created* nearly 70 years ago, the declared purpose of the legislature was not to promote the welfare of professional men or professional corporations—it was not to put down quackery, or even to advance medical science. The object in view was simply the interest of the public The preamble of the Act of 1858 consists of two lines only :—

> Whereas it is *expedient that* persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners ; Be it therefore enacted.

The preamble, as will be seen recognises two kinds of practitioners : the *qualified* " and the ' unqualified." Up to that time (1858) no easily understood line was drawn between the two, and when the public desired to make a choice, they were frequently at a loss The Act set up machinery for, as it were, ' hall marking " the qualified practitioner, so that he might easily be recognised when his services were required But the public were *left free* then, as they are free now, to seek ' medical aid ' from the unqualified practitioner if they like And the unqualified practitioner was left free then, as he is free *now, to practise for* gain among those who choose to employ and pay him He was forbidden, under penalties, to pretend that he was qualified, by *taking* a title he did not possess ; he might not use the courts for the recovery of his charges ; he could not give a valid certificate of sickness or death , *and now* by the Regulations *made under* the Dangerous Drugs Act he cannot prescribe certain dangerous drugs, like cocaine or morphine ; but except for these and a few other not *very inconvenient* disabilities, he was untouched by the law.

On the other hand the ' qualified " men, as a set-off to their new legal status and official recognition were subjected *to a new* central control, educational and disciplinary They obtained *no monopoly* of practice among the public in general They were afforded no special ' protection *against* the competition, not always scrupulous or insignificant, of the uncontrolled *unqualified* practitioner

The qualified practitioners might fairly have claimed that it would be good *for* the public, as well as for themselves, if monopoly of practice, and protection against the competition of the untrained, had been conferred upon them In other countries, and in other parts of the King's dominions, the restriction of practice to the qualified is with general consent and approval enforced by law There, *any* unqualified person who habitually and for gain practises or holds *himself out as practising* any *branch of medicine or* surgery is liable to severe penalties In this country, indeed the practice of dentistry and the practice of midwifery have been by law restricted to qualified persons But in these days it requires some resolute ignoring of the *signs* of the times to believe that, in this free country, legislation restricting the practice of *medicine* and *surgery* to qualified persons only is either probable or possible in the near future

In one significant respect, however, the Council is empowered to *protect* " the *aspirant to qualification*—not against the competition of the unqualified, *but against the possible action* of the licensing bodies in restricting his freedom when qualified. Section 23 of the Medical Act, 1858, reads thus —

> 23 *Privy Council may prohibit attempts to impose restriction as to any theory of medicine or surgery by Bodies entitled to grant certificates.*—*In case it shall appear to the General* Council that an attempt has been made by any body, entitled under this *Act to grant qualifications to impose* upon any candidate offering himself for examination an obligation *to adopt or refrain from adopting the practice* of any particular theory of medicine or surgery as *a* test or condition *of admitting him to examination or of granting* a certificate it shall be lawful for the said Council to represent the same *to His Majesty's Most Honourable Privy* Council and the said Privy Council may thereupon issue an injunction to such body so *acting, directing* them to desist from such practice ; and in the event of their not complying therewith then to order that such body shall cease to have the power of conferring any right to be registered under this Act so long as they shall continue such *practice*.

Once a *practitioner* has been trained and tested in the knowledge essential for public safety, he may adopt any theory " of medicine or surgery in which he honestly believes.

The instrument which Parliament set up for the purpose of marking the *distinction between qualified* and unqualified persons is called the Medical Register And the *making and* keeping of this Register is entrusted to the Medical Council. On the Register are placed the names of those who have passed certain tests of professional fitness These are called registered practitioners, and these alone the law declares to be duly or legally qualified The Council *has to see* that the tests of professional fitness *actually applied* by the examining bodies *to aspirants for* registration are sufficient " The tests must ensure that all *those who pass them* possess ' the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery ' The Council has also to see that no registered person who by crime or misconduct *has* become unworthy of the legal status which registration confers shall remain on the Register In other words, the two great functions which the Council in the public interest discharges are, first, to prevent the unfit from gaining access to the Register ; and, secondly, *to* remove the unworthy from it Except as to a few subsidiary matters such as the preparation and issue of the British *Pharmacopœia*, the control of diplomas in public health, the *scrutiny of the* midwives rules and the like, all its powers and all its work in relation to the *medical* profession have *reference to* these two functions It is a council of education and a board of registration, under the supervision of the Privy Council, which may direct it *to amend its* errors, if any, *or supersede* it if it persists in them.

The performance by the Council of its duties in regard to education are not *at present* in question, and it is therefore not necessary to enlarge upon this aspect of its work ; but it has been necessary to set down the foregoing in order to show how large a part of its duties are connected with education, and why the members elected by the universities and appointed by the Crown have hitherto been members of the medical profession rather than laymen.

in the view that the money spent on health insurance improves the health of the worker, they thought it quite a matter of speculation whether the expenditure was repaid by the greater efficiency, wage-earning capacity, and general contentment of the workers. The first consideration was the fullest possible measure of employment, and if more money was being taken out of industry than was essential for the existing statutory benefits, the view of the employers was that this was harmful to industry and therefore to the workers. They were not prepared to say by exactly how much the contributions could be reduced, but thought that the Government actuary might be a little more optimistic in his views, and in any case they suggested that the burden would be more equitably distributed if the taxpayer paid a higher share, and the employer, as such, a smaller share as the counting of heads of the numbers employed did not give the most equitable distribution of the burden.

# THE GENERAL MEDICAL COUNCIL.

## MEMORANDUM AS TO THE CONSTITUTION, FUNCTIONS, AND PROCEDURE.

BY THE REGISTRAR.

THERE is so much misconception at the present moment in regard to the General Medical Council, not only amongst journalists and the public, but amongst members of the medical profession themselves, that it seems advisable to give accurate information on the subject, in order that it may be more widely known how the Council is composed, what are its duties, and how these are carried out. What follows may be found in the documents prefixed to the Medical Register, in the published minutes and standing orders of the Council, in the public addresses of the President, and in Harper's "Legal Decisions upon the Medical and Dentists Acts" (Constable and Co.).

### *Constitution.*

The Council was constituted under the Medical Act, 1858, and its composition was somewhat altered by the Act of 1886. It now consists of 18 members appointed by the universities in the United Kingdom having medical faculties; of 9 members appointed by the medical corporations, such as the Royal Colleges of Physicians and Surgeons; of 5 members appointed by His Majesty in Council; and of 6 members directly elected by members of the profession as a whole—a total of 38. To these are added 3 dentists who are members of the Dental Board and are appointed for dental business. The universities may appoint either medical men or laymen; generally it is not the medical faculty of the university that appoints the member, but the academic governing body, whatever that may be. In Cambridge, for example, he is elected by the members of the Senate, in the same way as the representatives in Parliament. The representatives of the medical corporations must be members of these bodies, and consequently must be registered practitioners. The representatives nominated by His Majesty in Council are generally appointed for special reasons, relating to departments of the public medical service. For instance, the chief medical officers of the public health departments in England, Scotland, and Ireland have been or are among them; the medical editor of the British Pharmacopœia, 1914, was recently appointed by the Crown with reference to his special knowledge of this department; for many years before the formation of the Dental Board, Sir Charles Tomes was appointed to represent dentistry; Sir Francis Champneys, the chairman of the Central Midwives' Board for England, was appointed soon after that body came into being, when the rules of the Board became subject to the approval of the Council; and so on. The direct representatives are practitioners elected, four from England, one from Scotland, and one from Ireland, by ballot of all the members of the profession having registered addresses in these countries respectively. The nominees of the Privy Council and the direct representatives of the profession are appointed for five years. The representatives of the universities and medical corporations may be appointed for five years or less.

It will thus be observed that the 18 members appointed by the universities, and the five members appointed by His Majesty in Council, may all be laymen; but so far no laymen have been appointed. As will be seen later, the functions of the Council are largely concerned with medical education, and consequently the universities have found it expedient to appoint members of their body conversant with this subject, and the Privy Council have found it desirable to appoint persons having special knowledge of certain subjects of public importance, which might not otherwise be represented.

It is important that the constitution of the Council should not vary too quickly, because the Council meets only twice a year, and its executive committee only three or four times. It naturally takes some time for members to become acquainted with their duties. Moreover, it is important that members should have some knowledge of precedents in regard to education and to judicial decisions. And again, when applications are received from practitioners whose names have been erased from the Register for their restoration thereto, it is desirable that there should be members present who were in attendance when the case was originally heard, and therefore have the circumstances in their personal recollection.

### *Functions.*

Sins of commission—more often sins of omission—are freely laid to the Council's account, of which, from its very nature and constitution, it cannot be otherwise than guiltless It is reprimanded for doing what the law says it *shall* do. It is bitterly reproached for leaving undone what the law gives it neither power nor means to do. It is spoken of at one time as the "Parliament of the profession," yet it has no authority to legislate for anybody, and it cannot make even a by-law for any but its own proceedings. At another time it is scornfully described as a "doctors' trade-union"; yet it cannot legally levy an annual subscription, or say a word on the matter of rates of pay, or hours of work, or disputes with employers, or theories of practice; it offers no pecuniary benefits or strike-pay; and it *can* be sued in the courts like any other corporation. It exists, in fact, for the protection of the public, not of the profession.

The Council is, in fact, neither a parliament for making professional laws nor a union for protecting professional interests.

When the Council was created nearly 70 years ago, the declared purpose of the legislature was not to promote the welfare of professional men or professional corporations—it was not to "put down quackery," or even to advance medical science. The object in view was simply the interest of the public. The preamble of the Act of 1858 consists of two lines only:—

> "Whereas it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners: *Be it therefore enacted*. . . ."

The preamble, as will be seen, recognises two kinds of practitioners: the "qualified" and the "unqualified." Up to that time (1858) no easily-understood line was drawn between the two, and when the public desired to make a choice, they were frequently at a loss. The Act set up machinery for, as it were, "hall marking" the qualified practitioner, so that he might easily be recognised when his services were required. But the public were left free then, as they are free now, to seek "medical aid" from the unqualified practitioner if they like. And the unqualified practitioner was left free then, as he is free now, to practise for gain among those who choose to employ and pay him. He was forbidden, under penalties, to pretend that he was qualified, by taking a title he did not possess; he might not use the courts for the recovery of his charges; he could not give a valid certificate of sickness or death; and now by the Regulations made under the Dangerous Drugs Act he cannot prescribe certain dangerous drugs, like cocaine or morphine; but except for these and a few other not very inconvenient disabilities, he was untouched by the law.

On the other hand, the "qualified" men, as a set-off to their new legal status and official recognition, were subjected to a new central control, educational and disciplinary. They obtained no monopoly of practice among the public in general. They were afforded no special "protection" against the competition, not always scrupulous or insignificant, of the uncontrolled unqualified practitioner.

The qualified practitioners might fairly have claimed that it would be good for the public, as well as for themselves, if monopoly of practice, and protection against the competition of the untrained, had been conferred upon them. In other countries, and in other parts of the King's dominions, the restriction of practice to the qualified is with general consent and approval enforced by law. There, any unqualified person who habitually and for gain practises or holds himself out as practising any branch of medicine or surgery is liable to severe penalties. In this country, indeed, the practice of dentistry and the practice of midwifery have been by law restricted to qualified persons. But in these days it requires some resolute ignoring of the signs of the times to believe that, in this free country, legislation restricting the practice of medicine and surgery to qualified persons only is either probable or possible in the near future.

In one significant respect, however, the Council is empowered to "protect" the aspirant to qualification—not against the competition of the unqualified, but against the possible action of the licensing bodies in restricting his freedom when qualified. Section 23 of the Medical Act, 1858, reads thus:—

> "23. *Privy Council may prohibit attempts to impose restriction as to any theory of medicine or surgery by Bodies entitled to grant certificates.*—In case it shall appear to the General Council that an attempt has been made by any body, entitled under this Act to grant qualifications, to impose upon any candidate offering himself for examination an obligation to adopt or refrain from adopting the practice of any particular theory of medicine or surgery, as a test or condition of admitting him to examination or of granting a certificate, it shall be lawful for the said Council to represent the same to His Majesty's Most Honourable Privy Council, and the said Privy Council may thereupon issue an injunction to such body so acting, directing them to desist from such practice; and in the event of their not complying therewith, then to order that such body shall cease to have the power of conferring any right to be registered under this Act so long as they shall continue such practice."

Once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any "theory" of medicine or surgery in which he honestly believes.

The instrument which Parliament set up for the purpose of marking the distinction between qualified and unqualified persons is called the Medical Register. And the making and keeping of this Register is entrusted to the Medical Council. On the Register are placed the names of those who have passed certain tests of professional fitness. These are called registered practitioners, and these alone the law declares to be duly or legally qualified. The Council has to see that the tests of professional fitness actually applied by the examining bodies to aspirants for registration are "sufficient." The tests must ensure that all those who pass them possess "the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery." The Council has also to see that no registered person, who by crime or misconduct has become unworthy of the legal status which registration confers, shall remain on the Register. In other words, the two great functions which the Council in the public interest discharges are, first, to prevent the unfit from gaining access to the Register; and, secondly, to remove the unworthy from it. Except as to a few subsidiary matters, such as the preparation and issue of the British Pharmacopœia, the control of diplomas in public health, the scrutiny of the midwives' rules, and the like, all its powers and all its work in relation to the medical profession have reference to these two functions. It is a council of education and a board of registration, under the supervision of the Privy Council, which may direct it to amend its errors, if any, or supersede it if it persists in them.

The performance by the Council of its duties in regard to education are not at present in question, and it is therefore not necessary to enlarge upon this aspect of its work; but it has been necessary to set down the foregoing in order to show how large a part of its duties are connected with education, and why the members elected by the universities and appointed by the Crown have hitherto been members of the medical profession rather than laymen.

The Medical Council is also a Board of registration. In fulfilment of this function, partly by the force of necessity, and partly in virtue of the interpretation of the law by judges, it has become a professional court of justice, a domestic forum for the trial and determination of grave charges brought against registered practitioners in their professional capacity. By successive judicial decisions of the High Court and Court of Appeal, it has been laid down that in its procedure the Council, sitting as a tribunal, must as nearly as possible follow the forms and rules customary in other courts. But it has no authority to compel the attendance of witnesses, to administer oaths, or to call for the production of documents. It has only one judgment to give when a charge of misconduct is proved to its satisfaction—namely, "guilty of infamous conduct in a professional respect"; and only one sentence when judgment is given—namely, "erasure from the Register." From this sentence and judgment, given after proper inquiry and without malice, the High Court of Justice has pronounced that there is no appeal. In the earlier years of the Council's life, its decisions were frequently called in question before the higher courts of law. The results were on the whole fortunate, for while its actual findings as a professional tribunal were never reversed, the judgments delivered on these appeals not only defined, but in effect prescribed, the jurisdiction of the Council. They laid down its procedure, they interpreted broadly the meagre language of the Statute, and they settled beyond dispute the finality of its judicial decisions in all causes within its competence.

All the Act says is :—

> "If any registered medical practitioner shall be convicted in England or Ireland of any Felony or Misdemeanour, or in Scotland of any Crime or Offence, or shall after due inquiry be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they see fit, direct the Registrar to erase the name of such medical practitioner from the Register."

In 1863 the Lord Chief Justice and his colleagues of the Queen's Bench laid it down that this clause

> "makes the Medical Council sole judges of whether a medical practitioner has been guilty of infamous conduct in a professional respect; and this Court has no more power to review their decision than they would have . . . of determining whether the facts had justified a conviction for felony or misdemeanour under the first branch of the section. . . . The Council is the tribunal to whom the Legislature has left the decision, as being the best judges in the matter, and this Court cannot interfere."

In another appeal Lord Justice Bowen declared that, provided "due inquiry" had been made by the Council—

> "the jurisdiction of the domestic tribunal, which has been clothed by the Legislature with the duty of discipline in respect of a great profession, must be left untouched by Courts of Law."

Referring to the language of the Statute, Lord Justice Fry added :—

> "'Inquiry,' and 'judgment,' and 'guilt' are all words which express and which are relevant to a proper form of judicial proceedings, and, therefore, although this body proceeds by different rules of evidence from those on which Courts of Law proceed, I cannot for a moment doubt that the Council were proceeding judicially, nor can I help adding that the manner in which the Council has proceeded on this inquiry, as on all other inquiries, shows that the Council are fully aware that they are performing judicial duties, and endeavour evidently to perform them in a very admirable manner."

These and like judgments settled the jurisdiction and the procedure of the Council sitting as a tribunal. The meaning and scope of the statutory verdict of the Council—"guilty of infamous conduct in a professional respect"—were given by the definition of the Court of Appeal in 1892.

> "If it is shown that a medical man, in the pursuit of his profession, has done something with regard to it which would be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency, then it is open to the Council to say that he has been guilty of 'infamous conduct in a professional respect.'"

The words, "infamous conduct," in fact, constitute a technical legal expression, defined by the Lords Justices to mean conduct "disgraceful or dishonourable" in a qualified professional man acting as such.

### *Procedure.*

It will now be convenient to consider the way in which the Council carries out the duties imposed upon it under Section 29 of the Act, quoted above. It will be seen that the inquiries take place under two heads—viz., those relating to convictions, and those relating to "infamous conduct." To deal with all such cases, the Council has set up a special committee of five, which, assisted by the judicial assessor and the solicitor, acts the part of a grand jury, and considers whether there is prima facie evidence calling for a formal inquiry by the Council, or whether the circumstances suggest that a letter of warning may suitably be sent, or whether in the absence of relevant evidence no further action is necessary.

With regard to convictions, the Council, by the direction of the Home Office in England, and the corresponding authorities in Scotland and Ireland, receives from the police all over the kingdom reports of convictions of medical practitioners for any offence whatsoever. Some of these are trivial, such, for instance, as having the number-plate of a motor-car unlighted, or exceeding the speed limit. In these cases the Council, as a rule, takes no action beyond recording the fact of the conviction. Other cases may be those of convictions for drunkenness, and unless this conviction is for an offence committed when in attendance on a patient, or (say) when in charge of a motor-car, it is usual to issue a warning to the convicted practitioner. But should further convictions of the same sort be reported, the committee may think that they indicate a habit of intemperance which might be dangerous to the practitioner as a professional man and to the patients under his charge; in this case it might be decided that for the protection of the public the practitioner should be summoned to appear before the Council. There are other convictions of a still more serious nature, such as those of felony, in which, obviously, the Council ought forthwith to consider the matter in relation to the practitioner's professional status, and to the good repute of the Register.

If an allegation of "infamous conduct" is received, the Standing Orders, which are published by Messrs. Constable and Co., prescribe that the complaint must be formulated in writing, stating the grounds of complaint and accompanied by one or more statutory declarations as to the facts alleged. The practitioner, if the complaint is relevant to his profession, is then asked to give such explanation of the matter in writing as he may think fit, and the complaint and the answer thereto are brought before the committee. If, in their opinion, a prima facie case has been made out to justify an inquiry by the Council, the practitioner is in due course summoned to appear. In cases in which a practitioner has been under the censure of a judicial or other competent authority in relation to his professional character, as the result, for instance, of an inquiry into professional conduct held under the National Insurance Acts, or of a trial in the civil courts, statutory declarations by the authority in question are not required; but the depositions, judgments, and other relevant documents, are officially supplied, and in other respects the same procedure is followed by the Council.

When the inquiry takes place, the complainant or complainants may be represented by counsel or solicitor, or in the event of there being no personal complainant or lawyer representing him, as for instance in the case of a criminal conviction, the facts may for convenience be laid before the Council by its own solicitor, who formally proves the conviction and informs the Council of the circumstances as reported. The practitioner is entitled to be, and as a rule is, present; and he also may be represented by counsel or solicitor. The hearing is in public, witnesses are called and examined and cross-examined, as in the ordinary courts of law. Questions may also be put to witnesses by members through the chair. The judicial assessor is always present to assist the Council in regard to any points of law or procedure which may arise, and if there is a conflict of evidence, he, as a rule, sums up and indicates the legal weight to be attached to each part, in the same way as a judge sums up for a jury When a criminal conviction has been proved, it has to be accepted as a fact, and the Council does not retry" the charge which led to the conviction, any more than, according to Lord Chief Justice Cockburn, the High Court would do; but it is willing to hear anything that the accused practitioner may have to say, or may desire to be said on his behalf, in regard to the actual gravity of the offence of which he was found guilty, and in particular to its relevance to his profession, as affecting his position on the Medical Register. At the conclusion of the hearing the public and the parties withdraw, including the Council's solicitor, if he has been called on to lay the actual facts before it, and the Council then deliberates upon the case in camera. It decides first, whether sufficient evidence has been produced to enable it to come to a decision on the facts alleged; secondly, whether the conviction or facts alleged in the charge have been proved to its satisfaction; thirdly, whether it will proceed to judgment at once, or postpone it to a future date; and fourthly, if it does not postpone judgment, whether, on the facts proved, the name of the practitioner is to be erased on the ground that he has been convicted of a grave offence, or is guilty of "infamous conduct in a professional respect." A full shorthand note of the whole proceedings is taken, and copies are accessible if they are required, either by the Council itself or by any competent authority

The practice of suspending judgment to a later date is one which has been gradually evolved by the Council. The Act gives one penalty only—viz., that of erasure—but there are cases in which, when a practitioner has, for instance, been repeatedly convicted of drunkenness and promises amendment, the Council suspends judgment in order that he may have time to show that his word is good, and in this event the practitioner is summoned to appear in 6 or 12 months' time and to produce evidence as to his good conduct in the interval. At the adjourned hearing, if the evidence of conduct is satisfactory, the Council, although it may have found the conviction or the facts, as the case may be, to have been proved, does not deem it necessary to proceed to judgment or to direct the erasure of the name from the Register, and the accused practitioner is "discharged with a caution." The minutes of the Council record many examples of such "cautions."

The Act gives the Council no explicit power of suspension, nor, in view of the fact that practice by unregistered persons is not prohibited, would mere suspension from the Register be of any practical value to him. A practitioner's name is either on or off the Register. If it is on the Register, he is entitled to all the privileges of registered persons, and these could not be suspended in the case of an individual without the actual erasure of his name. He must have all or none.

A practitioner whose name has been erased may, under the conditions set forth in the Standing Orders, apply to have it restored, and, if in the opinion of the Council it will not be prejudicial to the public interest to grant his request, his name is thereupon replaced upon the Register It may here be remarked parenthetically that the Council has no jurisdiction over the licensing bodies in regard to the withdrawal, under their by-laws, of their qualification from one of their own members or licentiates. Certain bodies, for instance many of the universities, have no statutory power to withdraw their degrees once they have been conferred. Others, such as the Royal Colleges of Physicians and Surgeons, have power, independently of any action by the Council, under their own by laws to suspend or expel their members for offences involving a breach of their particular regulations or of the practitioner's declaration on admission. When a practitioner applies for restoration it is essential, in order to conform to the law, that he should actually be in possession of at least one qualification, for restoration is in effect re-registration. If he is not, the Council has no power to restore his name only, for he is, in fact, unqualified. He must therefore first apply to the bodies whose qualifications he formerly held, asking to have at least one qualification restored to him In this matter the licensing bodies have necessarily complete autonomy. They are not bound either to await or to follow a decision by the Council. It is the custom of the Council from time to time to issue warning notices to practitioners in regard to points of professional conduct, and it has been the practice not to issue such a warning until a number of cases of a particular form of misconduct have been brought before the Council, so that it is clear that a state of things is becoming prevalent which is contrary to the public interest. For instance, in certain parts of the country it was formerly customary for a qualified man in large general practice to employ a number of unqualified persons as his assistants. These, as they acquired a certain amount of rule-of-thumb experience, were gradually entrusted more and more with the sole care of patients. The practitioner sometimes did not see the patient until it was time to sign a death certificate in order to avert an inquest. Individual cases of gross abuse were one by one brought before the Council and condemned. Others, in which serious forms of evasion of the law were attempted, followed upon these; and as they arose these ingenuities were severally met and dealt with At length it was made clear to those who clung to the bad tradition that their practice was too dangerous to be profitable, and that the "unqualified assistant" must go. Having accumulated a sufficient body of experience regarding the mischief which had to be remedied, the Council summed up all in a "warning notice" respecting the professional offence of "covering." All qualified practitioners were notified that the abuse of their qualifications, whereby an unqualified person was enabled to mislead the public and to treat patients as if he were qualified, under "cover" of his qualified employer or employee, who might sign for him his medical certificates, and otherwise enable him to evade the law, was in its nature fraudulent and dangerous to the public health, and that such an offence rendered them liable to be judged guilty of "infamous conduct." The result was remarkable. Unqualified assistants were dismissed wholesale, often no doubt at the cost of some hardship to individuals, but in the end for the good of the public and the profession alike. The evil, from being almost endemic in particular districts, became sporadic, and has now almost passed away. Other forms of "covering," such as those by which uncertified women were enabled to practise as midwives, and other unqualified practitioners were enabled to procure medical certificates from the qualified, were one by one dealt with as they arose. Private "interests" must not prevail against the interest of the public.

More recently the practice of advertising, whether directly or indirectly, for the purpose of obtaining patients or promoting a practitioner's professional advantage, was brought before the Council in connexion with some particularly flagrant cases; and each case had to be judged on its merits—or demerits. The character of the advertising varied. In some cases articles were inserted in the press, either by the practitioner himself or through the medium of complaisant journalists, affirming directly or by implication the superior methods of treatment of a practitioner, who desired for gain to attract patients to himself at the cost of his self respect and the respect of others. If this procedure were unchecked, the practitioner who had fewest scruples, in praising himself and his wares, would reach the widest public, and extend his practice without any guarantee that his merits were in fact superior. It was discreditable to his profession, and contrary to the public interest, that a qualified man should thus adopt the methods of the unqualified self-advertising and self-praising practitioner of medicine or surgery. Accordingly the Council warned the profession against conduct of that kind, and, where a formal and duly attested complaint of such conduct is received, it holds an inquiry into the alleged facts. When the inquiry elicits evidence of deliberate bad faith, or of wilful exploitation of the public for gain, the offence of "unprofessional advertising" is naturally held to be aggravated.

To sum up, what has been written in regard to the disciplinary procedure of the Council, it is clear, first, that the Council does not itself initiate proceedings, does not itself employ detective methods, and does not itself act as prosecutor, against registered practitioners. It is a statutory court of justice, and takes action only in cases of criminal conviction, or of judicial censure, officially brought to its notice, or in cases of formal complaints, supported by prima facie evidence, brought before it by responsible persons or bodies. Secondly, its judicial procedure is based as nearly as may be on that obtaining in the Law Courts. When a charge is made the practitioner has every possible opportunity of defending himself; and should his name be erased from the Register, it may after a lapse of time be restored thereto, if that can be done with safety to the public. And thirdly, it is now unusual for complaints involving a charge of "infamous conduct" to be lodged in regard to any matter on which the Council has not already issued a general warning to the profession and to the public.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Proposed Insurance Legislation.*

A PREVIOUS letter outlined proposed French legislation on obligatory insurance against sickness, old age, and unemployment. The French medical profession has not been favourably impressed with the social insurance in vogue in England and in Alsace and Lorraine. Objection is taken to the frequent demands for needless consultations and the insufficient payment of physicians. After making all necessary allowances, the introducer of the new French law assigns 1·20 per cent. of the basal workers' salary of 5000 francs per annum to cover pharmaceutical, hospital, and medical expenses. Jayle finds that of the 60 francs thus forthcoming the physician is to receive 27 to 30 francs for seven days' medical service, and considers that no country provides adequate compensation for the physician, although the sums paid in England are twice those proposed in France. Insurance practice must remain imperfect and poor unless physicians unite to exact a payment which they consider suitable. If their demands are not made unitedly it may be that clinics will multiply, but their medical personnel will certainly be inferior. The result will be overloading of the free public hospital service, and the proposed law will not ameliorate present conditions. If physicians' unions, or *syndicats*, support what are considered just medical demands, the difficulty will be to compromise between these demands and the funds really available from the insurance treasuries. The question is very difficult in all its aspects.

### *Tuberculosis in Bakehouses.*

In discussing night-work in bakehouses the advocates of reform and their opponents have advanced all sorts of medical arguments, based for the most part on statistics which are positively fantastic. Some have said that tuberculosis affects 70 per cent. of workers in bakehouses, whereas others have estimated the rate at only 5 per 1000. MM. Jacques Parisot and G. Richard have recently put before the Académie de Médecine some definite statistics which are particularly interesting now that the Senate is discussing a Bill for the suppression of night-work. From information collected in social hygiene dispensaries from 1921 to 1925 they have come to the conclusion that the mortality from tuberculosis amongst workers in bakehouses at Nancy works out at 10 per 1000, whilst the mortality for the rest of the population of the town varies between 2·5 and 3 per 1000. It is instructive to compare these figures with those obtained in an allied trade—the pastry-cooks—in which there is said to be no mortality and a morbidity of less than 1 per cent. The reason for the difference seems to be that bakehouse work lies outside present social regulations (night-work, no regular weekly day off), and that baking is done in unhygienic conditions which are often deplorable. These factors favour the onset of tuberculosis amongst the workers. A significant fact is that two-thirds of the people found suffering from tuberculosis —many of them with extensive lesions and tubercle bacilli in the sputum—go on with their work as usual. Apart from any possible risk of contaminating bread before it is cooked, there is obviously a certain danger from the inevitable soiling of bread as it is taken out of the oven into a dusty atmosphere saturated with bacilli. Mr. Cazeneuve, of Lyons, has indicated another point of importance to the trade which has received insufficient attention. It is all very well, he says, to take account of the suppression of night-work and the eight-hour day, but it must not be forgotten that the substitution of mechanical kneading for hand kneading would be a great improvement—an improvement as much in the interests of the worker as in that of the consumer.

### *Fitness of Railway Employees.*

A report on the physical examination of railway employees has been presented by Dr. Guillain, professor of neurology at the Salpêtrière. Guillain suggests that all French railway systems require a standard physical examination for the admission of employees to the service. Each employee should be examined every five years to the age of 50, and every three years after that age; vision should be examined every two years; cardiac patients should not be accepted for service; and employees addicted to alcohol should be discharged.

### *New Technique in the Treatment of Lupus.*

Dr. Aurégan, of Lannion, Brittany, has just presented to the Société de Dermatologie et Syphilographie a method for treating lupus which he has been testing since 1904. The method is new mainly in its special technique, but Prof. Sabouraud declares that it has been proved of great value. The lesions are anæsthetised and deeply curetted, and the wound is filled with an ample supply of very finely powdered potassium permangante crystals. The crust formed by the permanganate is removed in 15 to 20 days, cure being perfect in ideal cases. Uncured traces remaining may be eliminated by repetition of the treatment. All cases thus treated by Aurégan have remained cured and no case has needed more than three applications of the method, which is commended for its sureness, simplicity, and inexpensiveness.

### *Pain in the Hip.*

According to Dr. Calot, of Berck-sur-Mer, the cause of pain in the hip, at all ages, is very often entirely misunderstood. When it comes on in young children it is put down to coxalgia; in adults and old people it is often attributed to sciatica, lumbago, rheumatism, rheumatoid arthritis, and the rest. This observer, however, claims to have demonstrated that 90 times out of 100 above the age of 20, and in nearly 50 per cent. of cases below that age, the functional disturbances noticed are really due to a slight congenital abnormality of the form and adjustment of the two bones of the hip—abnormalities which have been present without sign or symptoms for 10, 20, or 60 years. They remain latent so long as there is no excessive strain, but if functional equilibrium is destroyed at any age by the effects of fatigue or a fall or some debilitating disease symptoms such as pain and limping are the result.

Clinical and radiographical examination make it possible, he says, to identify the real cause, which is, of course, the first step towards rational treatment.

### A New Anti-Tuberculosis Vaccine.

A vaccine presented by M. Grimberg to the Société de Médecine de Paris seems useful in the treatment of fistulous lesions. It is said to be colloidal and prepared by treating bacilli with very fine iron filings and the electric current. A two years' trial in some of the Paris hospitals appears to indicate that it merits further test.

Prof. Tiffeneau has been unanimously chosen to succeed Prof. Richaud in the chair of pharmacology at the Paris Faculté de Médecine.

Prof. Sébileau, oto-rhino-laryngologist at the Hôpital Lariboisière, has been made Commander in the Légion d'Honneur.

## UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

### Death-rate in the United States.

THE national death-rate in the United States has been estimated by the Commerce Department of the Government, at 11·9, on the basis of figures for 1924, as compared with 12·8 in 1923, 11·8 in 1922, and 11·6 in 1921. The figures cover the entire death registration area of the country, which accounts for about 88 per cent. of the population. Heart disease was the chief cause of death in the general registration area in 1924, accounting for 170,671 fatalities. This was a slight increase over the figures for the previous year. Cancer also took a heavier toll in 1924 than in 1923, 91,941 deaths being reported. Tuberculosis, on the other hand, showed a decline, the deaths from this disease numbering 89,724 in 1924 as compared with 90,782 in 1923. Cerebral hæmorrhage, pneumonia, and nephritis were other important factors in the mortality figures, while of the 75,745 accidental deaths motor-cars alone caused 15,528, compared with 14,411 in 1923. Both suicides and murders increased; there were 12,001 suicides in 1924 as against 11,257 in 1923, and 8120 murders as against 7878. In another statistical study the department has reported a further increase in deaths due to motor-car accidents in the principal cities of the United States. The total for the four weeks ending Dec. 5th last was 624. In New York proper, in 1925, street accidents caused 392 out of a total of 590 violent deaths, which includes 106 deaths by shooting. According to the reports of the traffic court the magistrates dealt with 82,252 cases, and 238 persons were charged with driving motor-cars when intoxicated.

### The Dreams of Children.

At the meeting of the American Psychological Association on Dec. 31st last Miss Phyllis Blanchard gave some results of tabulating the dreams of 300 children. Of the children examined 189 were able to tell their dreams, and of these the large majority were between the ages of 6 and 14 years. The intelligence of the group was fairly normal. The dreams were grouped according to the relative frequency of the subjects and according to motivation. The greatest number of dreams, 15·3 per cent., concerned the children's parents, and this number represented more than one-fourth of the dreamers. Next in frequency came dreams about animals with 11·3 per cent., then dreams of fear, of play, of falling, of robbers, and of death. As for motivation, 16·3 per cent. of the dreams seemed to represent wish fulfilments and 40·6 per cent. were apparently caused by fear; while 9·5 per cent. were a result of mental conflicts. Moving pictures were recorded as the cause in 6·3 per cent., and only 5·7 per cent. were attributed to sex.

### The Span of Life.

At a recent meeting of the American Sociological Society Dr. Harnell Hart, of Bryn Mawr College, predicted that the average length of life of human beings born in A.D. 2000 would be 100 years. Dr. Hart pointed out that the average expectation of life increased from 21 years in 1850 to over 50 years in 1910. Since 1850, he said, the average gain per decade had been three and two-tenth years, a rate of gain which would be maintained and even accelerated. In A.D. 2000 he thought the span would be lengthening at about the rate of eight years per decade, and therefore the expectation of life at birth would have reached about 104 years. This meant that the average person would live to be 104, and obviously many persons must live to be 200 or older in order to maintain such an average.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### The Medical Register.

Mr. James Burke, Minister of Local Government and Public Health, moved last week the first reading of the Medical Bill. It is proposed to continue the authority of the General Medical Council in the Free State for a period of six months from Feb. 21st, and to give power to the Executive Council to continue it for a further period of six months if so desired. The Minister said that it was necessary to pass the Bill if the whole position of the medical profession in this country was not to go into chaos. Though at present the matter was not finally settled, he thought that they had hit upon a plan to preserve the existing rights of students in Ireland without in any way derogating from the status of the country under the Treaty. He gave no details of his plan, but it is understood that some of the medical representatives made a suggestion that a council should be established with power to regulate practice in the Free State. This would perform its duties side by side with the General Medical Council and without interference from it. By such a scheme students taking their qualifications in the Free State could put their names on either or both registers as they might think desirable. If they wished to practise in Great Britain they would, of course, enter as heretofore on the General Register.

### Vaccination in Ireland.

At a meeting of the General Council of the Royal Academy of Medicine in Ireland it was resolved that "in view of the outbreak of small-pox in certain parts of England, following on the decline of vaccination in that country, the President and Council of the Royal Academy of Medicine in Ireland, having had their attention drawn to the decline of vaccination in this country, deem it their duty to urge the necessity for vaccination of all young children, and of immediate revaccination in the case of adults who are likely to come in contact with cases of small-pox." A similar resolution was passed recently by the Council of the Irish Medical Association.

---

MEDICAL TREATMENT AT SEA.—Mr. W. Pool, presiding at a meeting of the Liverpool, Bootle, Waterloo, and District War Pensions Committee on Jan. 12th, mentioned a ruling by the Ministry of Pensions in the case of an ex-Service man now employed as a seaman. The Ministry admitted that he required medical treatment, one of their own medical men having certified to that effect; but said that he could obtain it from his own panel doctor, and that this would not prevent him earning his living. They would not give him a treatment allowance. The Committee wrote asking whether it was the duty of a seaman to change his occupation when he applied for treatment. "Certainly not; the treatment can be given to him perfectly well by the doctor on board ship." The Ministry of Health were informed that, as the result of inquiries in the port, it was extremely doubtful whether shipowners or captains would employ a seaman knowing that he would have to be medically treated on board.

# Public Health Services.

## SOME ANOMALIES IN MEDICAL CERTIFICATION.

INSURANCE practitioners are sometimes in doubt of their correct course in the certification of an insured person who has been treated in hospital and who remains incapable of work on returning home. The practitioner sees the case for the first time when the patient returns home; should he give a "first" certificate or an "intermediate" or "continuation" certificate to follow on the certificates already given at the hospital? Obviously, if the insured person is not to lose two or three days sick benefit—and there is no reason why he should—*the certificate must be an* "intermediate" certificate. The case is similar to that of an insured person who changes his insurance doctor in the course of an illness. In this case the transfer may be due to the fact that the first practitioner has refused further certificates. We know of cases in which the second practitioner has given a "first" certificate under these circumstances.

Agents of some of the societies insist on a "final" certificate being given in cases of pregnancy when labour takes place. Here it is obvious that the ordinary "final" certificate cannot be used. The fact of labour taking place and the application for maternity benefit with which a signed statement of the date of the confinement must be sent is sufficient evidence of the date on which the sick benefit must cease.

Practitioners are frequently notified of their insured patients having "ceased to be insured." Where the practitioner knows that the insured person referred to is actually at work the explanation may be that the notice refers to a duplicate entry which has been discovered and which is being cancelled. But in other cases the approved societies in notifying the insurance committees appear to overlook the wide limit which was granted to insured persons by the 1920 Act. Under this provision the insured person is entitled to medical benefit for 12 months after the end of the year in which he falls into arrears. This provision was meant to prevent the insured person from being disentitled to medical attendance by reason of a period of temporary unemployment. So many cards are asked for by the Insurance Committee for this reason that the relationship between the practitioner and his insured patient is unnecessarily interfered with to the annoyance of both parties.

A number of insurance practitioners would like to have an answer to the following question: When an insured person is said to be in arrears to the amount of, say, 5*s.*, why is it necessary to stop an equivalent sum of his sickness benefit every week?

## PORT SANITARY AUTHORITY.

The annual report of the Newport (Mon.) Port Sanitary Authority by the medical officer of health, Dr. J. Howard-Jones, tells of but few cases of infectious disease seen during 1924. It is desirable, he states, that suspected ships should be moored and examined in Barry Roads, but this procedure has not yet been sanctioned by the Ministry of Health. Little meat or other provision imported was found unfit for human consumption. There came to notice 101 cases of venereal disease in British subjects and 74 in foreign seamen.

*Baits, traps, ferrets, and fumigation* accounted for 6583 rats, some 70 per cent. of which were females; 97 *per cent. of the rats on board ship* were black, whereas 99 per cent. of those about the docks were brown. None were found infected by plague. Less than six were found dead per hundred baits distributed, and in seven ships fumigated the average number of bodies found was 74.

Inspection was made of 2428 ships, of which 407 were found defective and had notices issued to them calling for the abatement of nuisances. These included dirty forcastles, 147; foul or defective w.c.'s, 141; defective lighting or ventilation, 118; accumulation of refuse on deck, 89; defective stoves and heating apparatus, 72; food-lockers, none, or defective, or dirty, 32; leaking decks, 23; living spaces verminous, 18; defective cable casings or hawse pipes, 18; stagnant water on or under floors of living spaces, 14; water impure or storage dirty or defective, 10; insufficient table space or seating, 8; w.c.'s used as storerooms, 6; *defective bulkheads*, 5. Of dirty or verminous beds, 1269 were destroyed. Those general *and particular remarks* of the report which concern the sanitary condition of ships and the diseases of seamen have already been commented upon in our columns.[1]

## INFECTIOUS DISEASE IN *ENGLAND AND WALES* DURING THE WEEK ENDED JAN. 23RD, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 362 (last week 341); scarlet fever, 1818 (last week 1717); diphtheria, 1005; enteric fever, 30; pneumonia, 1103 (last week 1337); *puerperal fever*, 51; cerebro-spinal fever, 9; acute poliomyelitis, 8; acute polio-encephalitis, 1; encephalitis *lethargica*, 31 *(last week* 67); *continued fever*, 1; *dysentery*, 8; ophthalmia neonatorum, 113. There were no cases of *cholera, plague*, or *typhus notified during the week.*

Of the 362 cases of small-pox, 26 (last week 60) were reported from the county of Derby, 19 of them from Derby C.B.; 175 (last week 143) from the county of Durham, 47 of these from Gateshead C.B., 9 from South Shields C.B., and the remainder from widely scattered urban and rural districts and including 44 from Blaydon, 20 from Chester-le-Street R.D., and 23 from Easington R.D.; 1 from the county of Lancaster; 1 from Lincoln (parts of Lindsey); 53 from the county of Northumberland (last week 21), including 6 from Newcastle-on-Tyne and 20 from Ashington; 8 from the county of Nottingham (last week 16); 6 from the East Riding of Yorkshire (Kingston-upon-Hull); and 92 from the West Riding (last week 90), of which 70 (*last week* 77) occurred in Rawmarsh and 2 in Leeds.

*Deaths.*—In the aggregate of great towns, including London, there was 1 death from enteric fever, none from small-pox, 100 (63) from measles, 5 (3) from scarlet fever, 66 (4) from whooping-cough, 50 (16) from diphtheria, 57 (10) from *diarrhœa* and *enteritis under* 2 *years of age*, and 87 (11) from influenza. The figures in parentheses are those for London *itself. The recent* diminution in the number of deaths from influenza is not maintained, the figures for the last three weeks, working backwards, being 87, 81, and 114.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. L. F. Strugnell to be Surg. Comdr.

The *following appointments have been made*:—Surg. Comdrs.: D. P. H. Pearson to the *Champion*; A. G. Malcolm *to the Pembroke, addl., for* R.N. Barracks, Chatham, and as specialist in ophthalmology; and T. E. Blunt to the *Spenser, temp.* Surg. Lt.-Comdrs: W. I. Gerrard to the *Egmont*, addl., and to the *Egmont* for R.N. Hospl., Malta, and as specialist in bacteriology; K. A. I. Mackenzie to the *Britannia*, for R.N. Sick Quarters, Dartmouth; J. F. Haynes to the *Vivid*, addl., for Devonport Dockyard; O. J. M. Kerrigan, S. R. Johnston, J. T. Wylie, J. F. Ainley, F. G. Hunt, H. Hurst, J. R. Brennan, and R. W. Nesbitt to the *President*, addl., for *five months'* course of instruction.

Surg. Lt. (short service).—P. J. A. The O'Rourke transferred to the permanent list.

## ROYAL ARMY MEDICAL CORPS.

Maj. A. L. Otway is restd. *to the* estabt.

Majs. C. T. Edmunds (granted the rank of Lt.-Col.) and A. S. Williams ret. on retd. pay.

Maj. B. G. Patch to be Lt.-Col., vice Lt.-Col. J. H. Robinson to retd. pay.

Capt. S. E. Elphick to be Temp. Capt. and temporarily relinquishes the rank of Capt.

Temp. Capt. A. Wilson relinquishes his commn. and retains the rank of Capt.

---

[1] THE LANCET, 1925, ii., 1347.

### TERRITORIAL ARMY.

Capt. A. J. Gibson to be Maj.
Lts. T. C. MacKenzie and J. Cohen to be Capts.
Lt. D. G. Coutts (late T.A. Res. of Off.) to be Lt.
2nd Lt. A. G. Ogilvie (late R. Tank Corps) to be Lt.

## ROYAL AIR FORCE.

L. I. Hyder is granted a short service commission as a Flying Officer for three years on the Active List.

Flying Officer S. G. Gilmore is promoted to the rank of Flight Lt.

Flying Officer T. Glynn is transferred to the Reserve, Class D.3.

### AUXILIARY AIR FORCE.

J. D. Driberg to be Flight Lt., No. 601 (County of London) (Bombing) Squadron.

## INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Cols. J H. Hugo and R. McL. Dalziel.

## DEATHS IN THE SERVICES.

Inspector-General of Hospitals and Fleets, Thomas Browne, R.N., whose death occurred at the age of 81 on Jan. 20th at Weymouth, graduated M.D. R.U.I. with honours and the gold medal in 1863. In the same year he obtained the L.R.C.S. Edin. and joined the Royal Navy as assistant surgeon in 1863. He was promoted to staff surgeon in 1870, to fleet surgeon in 1883, Deputy Inspector-General in 1803, and Inspector-General in 1809, in which year he retired. For some 14 years he served at the R.N. Hospital, Yarmouth, where he was very popular with the patients and their relations. From 1804 to 1807 he was in charge of the R.N. Hospital, Bermuda, and from 1807 to 1800 second in charge of the R.N. Hospital, Plymouth. A keen golfer, he assisted in the formation of the Great Yarmouth Club, of which he was the first honorary secretary. He married Miss Agnes Robertson Dall, daughter of James Dall, J.P., of North Berwick, in 1871, who survives him with a son and five daughters.

Lt.-Col. William Wippell Pope, C.M.G., R.A.M.C. retd., who died on Jan. 31st at Bournemouth, aged 68, received his first commission in 1881 and served with the Egyptian Expedition of the following year, and was at the battle of Tel-el-Kebir (medal with bronze star). In 1888 he took part in the operations in Zululand and served during the operations on the N.W. Frontier of India in 1807–08. He was also with the Tirah Expedition Force (medal with clasp), and served in the South African War, and was present at the defence of Ladysmith (Queen's medal with clasp). He reached the rank of Lieut.-Colonel in 1001 and retired two years later.

## THYROID GLAND AND CALCIUM THERAPY.

*To the Editor of* THE LANCET.

SIR,—In connexion with Dr. Geikie Cobb's letter on the above subject, and its application to the treatment of chilblains, may I invite the opinions not only of my dermatological colleagues, but also of other medical men, as to the value of calcium salts alone, or of a combination of these with parathyroid gland, in the treatment of patients with a feeble peripheral circulation and chilblains? Most of my patients who come to me with chilblains have already taken calcium lactate over a long period without striking benefit; it is true that many of them have taken it after meals, whereas, as Dr. Arthur Luff pointed out, it should be given about an hour before, but, even when this error is corrected, the results in my experience are seldom good. As for parathyroid gland, in spite of all the claims that have been made *for it* and of a conscientious personal *trial* in cases of chilblain-circulation, varicose and other chronic ulcers, and urticaria, I have never convinced myself that it had any beneficial effect whatever when given by the mouth.

Chilblains are admittedly far commoner in the female than in the male sex, and occur chiefly, but not exclusively, in girls and women belonging to a certain type, which deserves a monograph to itself. This type is well known to dermatologists *and is seen* commonly in girlhood, although it can be recognised at a later age, when, however, its manifestations are, as a rule, less obvious. Its subjects are usually fat and œdematous-looking and their legs are, perhaps, their most characteristic feature. These are coarse and unshapely and blue from vascular stasis, most marked in the lowest third, which is often icy cold to the touch; there is hyperkeratosis at the pilo-sebaceous orifices—*keratosis pilaris*—around each of which is seen a bluish halo of stasis; the lanugo hairs are often long and coarse, and the skin as a whole is harsh, feels thickened, and cannot be pinched up from the underlying subcutaneous tissue. The same vascular stasis and the *keratosis pilaris* are also seen on the extensor surfaces of the upper arm. Dr. H. MacCormac and Dr. Parkes Weber recently drew attention to these patients in describing "a peculiar erythema of the legs," and it has been suggested that the wearing of thin or openwork stockings *is an* aggravating cause of the vascular stasis. Where this is most evident—viz., on the postero-external surface of the lowest third—actual chilblains often occur, and also, if the patient be tubercular, the nodules of Bazin's erythema induratum; in fact, it is doubtful if the latter is ever seen except in patients of this type. I agree, however, with Dr. Guy that in them nodules similar to those of erythema induratum *may occur* from embolism of bacteria other than the tubercle bacillus—e.g., *B. coli* and streptococci.

The ætiological factors responsible for the production of this type afford plenty of scope for speculation. That there is a disturbance of the endocrine-sympathetic system would appear likely. Thus, as has been said, females are far more often affected than males, and my experience is that in most patients there are menstrual irregularities; menstruation is usually late in beginning, often irregular and scanty, and not uncommonly several periods are missed altogether. Heredity is undoubtedly a factor of importance; frequently the history is volunteered that the mother was similarly affected when a girl, and I have been several times consulted by two or three sisters for the same condition. I have thought that psoriasis is commoner in girls of this type than can be explained by mere coincidence; when it does occur, the psoriasis patches predominate on the legs below the knee and to a less extent on the extensor surface of the upper arm, the body often being completely free, and it is common in these situations for the eruption to be follicular, the mouths of the pilo-sebaceous follicles, already the site of *keratosis pilaris*, being encircled by a little halo of psoriasis. As regards the calcium metabolism of these patients Dr. W. W. Payne kindly made investigations of the blood-calcium for me in *a few cases, but the* results were inconstant; no striking diminution either of the total or ionised calcium was found in any case, and in some the figures were above normal.

I have found the oral administration of iodine in large doses, either alone or in combination with *thyroid* gland, far more efficacious than anything else in these patients, not only as regards the acro*asphyxia* and chilblains, but also as regards their general health and sense of *physical fitness.* I *am, of* course, aware that Sir Arbuthnot Lane would attribute the clinical picture I have briefly sketched entirely to intestinal auto-intoxication; it is true that in the few cases that have been completely investigated very marked delay in the colon was found, and very possibly auto-toxæmia may be an important factor, but it cannot, I think, be the *only* one.

I am, Sir, yours faithfully,

Devonshire place, W., Feb. 1st, 1926. H. W. BARBER.

## THYROID GLAND AND CALCIUM THERAPY.

*To the Editor of* THE LANCET.

SIR,—With regard to chilblains Dr. Cobb uses some work of Dr. Vines and mine to strengthen an argument which would have had more force if his major premise had been correct—namely, that chilblains are associated with calcium deficiency. We have shown that many diseases are associated with Ca. deficiency, but we have expressly stated that the cases of chilblains had normal blood calcium. Two only were examined, but these were sufficient. I do not know who originally stated that chilblains had Ca. deficiency; I can only assume that the blood of a person suffering from ulcerating chilblains was examined. In that case there might have been Ca. deficiency due to some septic source which would render the chilblain liable to break down. In the same way many people have varicose veins, but they do not all get them thrombosed or ulcerated. But if there is a source of sepsis in the system the blood will become Ca. deficient and the vein may inflame or break down into an ulcer. In such a case giving parathyroid will overcome the deficiency and the lesion will heal. There is no necessity to add calcium; there is always the little required in the food; it is only a question of its proper assimilation and ionisation. Chilblains are very deceptive things to treat; under any remedy a spell of warmer weather will improve them and the remedy is given the credit. Personally I was sure, before Dr. Vines had found out for me that chilblains *per se* were not Ca. deficient, that the administration of calcium salts did no good, and I have never tried parathyroid. On the other hand, thyroid has seemed to me to lessen the congestion. But some years ago a consul home for a holiday from the Caucasus asked me to give him some cacodylate of soda injections for his chilblains, an Armenian doctor having previously cured him with that remedy. I have always used it since with sure and happy results. The effect lasts for some months, and given as a prophylactic at the beginning of the winter, the patient is free for the year. I give three injections, each of gr. ¾ made up in ampoules, at intervals of about two days.

I am, Sir, yours faithfully,
W. R. GROVE.

St. Ives, Huntingdonshire, Feb. 1st, 1926.

## PERCHLORIDE OF MERCURY IN ACUTE BACTERIAL INFECTIONS.

*To the Editor of* THE LANCET.

SIR,—With reference to the article by Prof. Dudgeon in THE LANCET of Jan. 23rd, I venture to send you a note on similar work which we have been carrying out at the West London Hospital, St. Mary Abbots Hospital, and other places, and which we had intended to publish fully when sufficient cases had been collected to make it of value. Dr. Dudgeon has been able to deal with a large number of cases, with results that are as satisfactory as we would have anticipated from our experience.

Two cases of pyæmia were shown at the West London Medico-Chirurgical Society in 1924 and 1925 which had been treated with intravenous injections of perchloride of mercury with immediate and satisfactory results, inasmuch as the blood cultures became sterile at once and there was rapid recovery. In the second case panophthalmitis had necessitated the excision of the eyeball before treatment was started. Other injections had been given in both these cases previously with no effect. These cases appear in the *West London Medical Journal* in the reports of the Proceedings. Since then we have used the same injections in various infective conditions but our conclusions are not yet drawn. In several cases of subacute infective arthritis the condition appeared to subside with recovery, in others there was no result.

This winter several cases of pneumonia seemed to improve directly after injections, and the resident medical officers at the hospital have formed a high opinion of its value in pneumonia, but I am of opinion that it is in the so-called influenzal types that it is of more value. In the true lobar type due to the pneumococcus I am not convinced of its efficacy. But then in streptococcal infections in general, and particularly in infective endocarditis, we have been disappointed, and it is most encouraging to read the report of Dr. Dudgeon's success in a case of septicæmia associated with a hæmolytic streptococcus. In acute rheumatism there has been no improvement after several injections.

It is difficult to attempt to explain the action of so small a dose as 1/32 to 1/16 gr. of perchloride when diluted in the mass of body blood, but an interesting point appeared to come out of blood cultures made by Dr. Elsworthy on a case of infective endocarditis. Though the disease was not affected by the injections he noted that after each there was a distinct delay in the growth in the culture flasks. We have had no ill-effects of the injections, which have been given in 1 c.cm. of saline.

I am, Sir, yours faithfully,
JULIUS BURNFORD.

Devonshire-place, W., Feb. 1st, 1926.

## OCCUPATIONAL THERAPY.

*To the Editor of* THE LANCET.

SIR,—When I was young my little friends and I were wont to play a game in which, during a hunt after a hidden object, we were told we were getting "warmer and warmer" the nearer we approached the desired goal. It has struck me since that life is composed almost entirely of such a game, with this difference—that even if one knows for certain where the object is hidden, very rarely does one dare to shout "warmer and warmer" the nearer someone approaches it.

The discussion on Occupational Therapy by the Society of Superintendents of Tuberculosis Institutions (THE LANCET, Jan. 23rd, p. 182), which unfortunately I was unable to attend, seems to me so well to illustrate the game of our childhood, that I hope I may be forgiven if I make bold, even at the risk of being thought indiscreet, to shout "warmer and warmer" to my colleagues, for it would be hard to imagine a meeting which could pour forth such approbation of village settlements for the tuberculous, such an appreciation of the principles underlying them, without recognising the end of the quest.

I cannot, therefore, refrain from adding a few remarks which may help in the elucidation of a difficult problem. In the first place, it is well to have clearly fixed in our mind the kind of object for which we are searching. When, for example, Dr. J. E. Chapman states that occupational therapy signifies a means of returning the patient "to his ordinary conditions of life mentally and bodily sound," he is enunciating a fundamental principle, and when he adds, "but employers did not want them after discharge, and they had no notion of the commercial side of business and so failed alone," he is adding the next layer of bricks to the structure. Finally we come to the culminating point: "Many of them broke down more because of the *difficulties and worries of employment*"—that is where we are brought face to face with the economic problem. And this is emphasised by Lieut.-Colonel J. R. Lord, who remarks that "a patient would take more interest in his work if it were *useful and remunerative* . . . . Often their old occupation was gone and they had to face a new world and conquer it as best they could."

That an occupation should be useful will not suffice. Dr. Jane Walker gives a long list of admirably useful occupations which, with the utmost enthusiasm, she has tried at Nayland, and which she says have failed, but—and this is the significant fact—"when the Government scheme for ex-Service tuberculous men was instituted" various trades were commenced, and these "were still going on very successfully."

Why? Because those men were not financially embarrassed; their economic problems had been solved by the pension.

A *similar principle is recognised* by Dr. Esther Carling when she informs us how successful "the employment of ex-patients in institutions" has turned out to be; that is, employment under sheltered conditions—the germ of the village settlement—employment at an occupation which is already known to the ex-patient, or one nearly allied to it. The economic problem having been solved, success *is* attained. The sheltered environment, such as that in a village settlement, is emphasised by Dr. H. O. Blanford, who remarks that "one of the chief obstacles to the employment of ex-patients was the opposition *of the healthy employees.*" *Quite so*; such opposition does not occur in sheltered and specialised communities. Dr. W. C. Fowler gets very "hot" in the search when he says "the patient should be told the definite time he was likely to be kept in bed"; *that is, he should not be left in* uncertainty as to his economic future. Add to this the information that his economic salvation is assured, and the object of our search will be found to be in the industrial village settlement for tuberculosis.

I am, Sir, yours faithfully,

P. C. VARRIER-JONES.

Cambridgeshire Tuberculosis Colony, Papworth Hall,
Cambridge, Jan. 26th, 1926.

## CHARING CROSS HOSPITAL INSTITUTE OF PATHOLOGY.

*To the Editor of* THE LANCET.

SIR,—I should like to reply to the letter of the Secretary-Superintendent of the Hospital for Epilepsy and Paralysis published in your last issue.

He quite correctly points out that I have changed my mind about the propriety of placing the pathological resources of a large hospital at the disposal of the general practitioner. The Charing Cross Hospital Institute of Pathology—of which I have the honour to be Director—has so frequently been asked to perform tests for persons who have been unable to pay ordinary fees that I believe such an extension is more than justifiable. Furthermore, I am convinced that there is need for direct coöperation between the clinician and the pathologist, and as pointed out in our pamphlet the practitioner is welcomed and encouraged to come to these laboratories with any difficulty that he may experience and for information on any point which he may desire. This, in my opinion, is the soundest basis of clinical laboratory work, and for that class which this institute especially has in mind can best be carried out at one of those great hospitals to which medical men in this country look for guidance in such matters.

I can only regret the letter to which I once appended my name, although I cannot, of course, speak for the other signatories. If my previous letter in any way hampered the scheme of the Hospital for Epilepsy and Paralysis, I apologise most heartily, although at that time convinced that harm might arise.

I am, Sir, yours faithfully,

A. PINEY,
Director of the Charing Cross Hospital
Institute of Pathology.

Feb. 1st, 1926.

## CHEMOTHERAPY OF SYPHILIS.

*To the Editor of* THE LANCET.

SIR,—In a recent communication[1] to your columns and an address[2] to the Royal Society of Medicine on Jan. 21st, Dr. C. Levaditi, of the Pasteur Institute, Paris, has given an account of his experiments in the use of stovarsol in syphilis and other spirillary infections. He maintains that the drug is perfectly innocuous. With the greatest deference to his large experience, I feel it may be worth while to relate the following case in which untoward results followed its use. They have led me to think that the treatment is not quite unattended by danger.

A man, aged 46, of strong physique, with a past history of specific infection, consulted me on account of some mucous patches on the dorsum of the tongue. The Wassermann reaction in the blood was positive. He was given several intravenous injections of salvarsan which cleared up the patches. Recently there developed one or two slight ulcers on the tongue and I decided to try the effect of stovarsol, administering it in the usual way per os in tablet form. The dose was 0·25 g. (4 gr.), which is the quantity usually advised. This was taken about one hour after breakfast. Within two hours he was taken violently ill. Severe cramp-like pains developed over the abdomen and lower limbs, and especially in the calf muscles. There was much vomiting for two hours and also diarrhœa. The patient suffered from great prostration and collapse, and the pulse-rate rose to 138 with clammy sweating. At one stage he looked as though he would not recover, but after about three hours he began to pick up, though he remained in a weak state for some days.

Copious draughts of warm water were given to dilute the contents of the stomach, and also a ferric hydrate mixture. The symptoms were ominously suggestive of arsenical poisoning.

It is possible that stovarsol may produce these symptoms after food, as Dr. Levaditi recommends that it be taken before breakfast. It would be interesting to know if others have had a similar experience. It seems clear, however, from this case that stovarsol requires some discretion in its use.

I am, Sir, yours faithfully,

Hull, Feb. 1st, 1926. J. R. O'BRIEN.

## MANIPULATIVE TREATMENT.

*To the Editor of* THE LANCET.

SIR,—The discussion at the Medical Society of London (THE LANCET, Jan. 30th, p. 233) ought to be of immense service to the profession. Reading between the lines there is an admission of something seriously faulty in our system of medical education, and Mr. Elmslie goes further to show that there is also something wrong in our system of specialisation, when he remarks that "A surgeon who practically . . ." &c. (p. 221). Dr. H. A. Des Vœux speaks of the profession being on the "defensive." Though the general public recognises specialists and specialism, its main concern is with the general practitioner. Recognising that the General Medical Council controls medical education, it is naturally disappointed to find one or more of its guaranteed products to be failures, and especially when their mistakes are remedied by unrecognised and unguaranteed specialists. The General Medical Council ought to be on the *defensive* rather than members of the profession who are not on the Council.

More than half of the persons who are placed on the Register become general practitioners, yet the Council provides no training for them *as such.* As "clearing stations" they are excellent, but as real workers in the profession they are only on the threshold. A full physician or surgeon in a well-appointed hospital never leaves his beds in the sole control of his registered house physician or house surgeon.

The various specialised branches are catered for by diplomas such as those for public health, insanity, &c., but the general practitioner is thrown on the public trained only by men who have never been in general practice. When I say never I mean that few, if any, of the members of teaching hospital staffs have made a living as general practitioners, and such as there are rarely allow it, if ever, to be known. I venture to suggest that general practice is at least as much a specialty as that of a military or naval surgeon, both of whom receive special training before having charge of patients. In these days of specialism the general practitioner must be provided with a special diploma, after which it is less probable the profession will be placed on the defensive.

I am, Sir, yours faithfully,

Buxton, Jan. 31st, 1926. R. CRAWSHAW HOLT.

[2] THE LANCET, Jan. 30th, 1926, p. 215.

## PUBLIC MEDICAL SERVICE FOR LONDON.

*To the Editor of* THE LANCET.

SIR,—In your note on the above Service in your issue of to-day's date you state, "Administration expenses are to be met by an entrance fee of 1*s.* and a quarterly charge of 9*d.* per member. In other words, 3*s.* out of the capitation fee of 13*s.* goes to the administration account." This statement is incorrect. The entrance fee and quarterly levy are paid by the subscriber (the patient), not by the member (the doctor), therefore the payment is in addition to the 13*s.* per annum, not a deduction from it. One of the principles of the scheme is that the capitation fee for the practitioner shall be 13*s.* per annum net.

I am, Sir, yours faithfully,
C. LUTHER BATTESON,
Secretary of the Public Medical Service for London.
Staple House, Chancery-lane, W.C., Jan. 30th, 1926.

# Obituary.

## PROF. CAMILLO GOLGI.

Camillo Golgi, emeritus professor of general pathology and histology in the University of Pavia, who died on Jan. 21st, had almost reached his eighty-fifth year; yet until a short time ago he preserved to the full the lucidity of his astonishing mind. The honorary fellowship which the Royal Society of Medicine recently conferred on him proved the last of a long series of honours which came deservedly from every part of the world.

Son of a distinguished practitioner, Golgi graduated in medicine at Pavia in 1865. For some time he was a pupil of Mantegazza and Lombroso. It was not long before he became resident physician in the Home for Incurables of Abbiategrasso, which was then only a village in the province of Milan and rather remote from any centre of scientific activity. It was in Abbiategrasso, nevertheless, that Golgi wrote those early papers on the history of pellagra, the ætiology of mental alienations, the structure and development of psammomata, the changes of the lymph vessels of the brain, and the structure of the neuroglia, which made him famous and which even now can be read with great profit. In that home for incurables, where only the most primitive means of investigation were available, he discovered his chromate of silver method, the *reazione nera*, by which nerve-cells with all their processes, and the finest ramifications of those processes, are seen stained intensely black against a transparent yellow background. At a time when histological technique was in its infancy and the structure and functions of the central nervous system appeared as impenetrable mysteries, Golgi's discovery illuminated a world steeped in darkness. A first hint of the new method (the slow process) was to be found in his paper on the grey substance of the brain in 1873; the details were given more fully in a memoir in 1875, when he became extraordinary professor of histology in the University of Pavia. His rapid process was first described in a paper on the structure of medullated nerve-fibres in 1880; the bichromate and sublimate method had been published two years previously. All of them were dealt with again minutely in the last chapter of his monumental work "Sulla fina anatomia degli organi centrali del sistema nervoso," published between 1882 and 1885, and illustrated by 24 magnificent plates which were, unfortunately, much too detailed for reproduction in ordinary text-books.

By Golgi's methods the histology and physiology of the central nervous system were placed on the sound foundation on which they rest at present. Since 1873 he had observed the two types of nerve-cells with which we are now familiar and the collaterals arising from the axon of the cells of the I. type. Already, in 1874, he had described the large nerve-cells of the granule layer of the cortex cerebellæ which bear his name, and had pointed out that the so-called granules were, in fact, minute nerve-cells. In 1875 he had been able to give a first description of the structure of the olfactory bulb and to show that both the olfactory fibres and the protoplasmic processes of the mitral cells arborise within the olfactory glomeruli. In his main work he set forth definitely his fundamenta observations on the morphology and relations of nerve-cells, the central origin of nerves, the architecture of some of the cerebral convolutions, and the structure of the cortex cerebelli and hippocampal region, adding the results of fresh investigations on the morphology, vascular connexions, and histogenesis of neuroglia cells. These studies, and those on the spinal cord (1880 and 1890), led him on to describe his diffuse nervous network and to refute persistently the neurone theory which others had built on the results of his methods.

His other discoveries form a long list. Mention should at least be made of his work on sensory end-organs in tendons (1880), the course of uriniferous tubules (1889), the secretory canaliculi of the oxyntic cells of the stomach (1893), the pericellular investment and internal apparatus of nerve-cells (1898), and the neurofibrils of the superficial portions of nerve-cells (1900). Of his investigations in the field of pathology it will suffice, perhaps, to recall his epoch-making observations on malaria, and his masterly description of the morphological and biological characteristics of the parasites of tertian and quartan fever. Golgi it was who discovered their monogonic cycle of development and first showed that the beginning of the fever coincides with the sporulation phase. No wonder that his name has already become legendary among medical and science students.

## CHARLES PLUMLEY CHILDE, F.R.C.S. ENG., M.R.C.P. EDIN.,

### CONSULTING SURGEON, ROYAL PORTSMOUTH HOSPITAL.

WE regret to record the death of Mr. Charles Plumley Childe, the well-known Portsmouth surgeon, which occurred on Jan. 29th at Monte Carlo of heart failure following pneumonia.

Childe was the elder son of the late Rev. G. F. Childe, sometime professor of mathematics in the South African College and assistant astronomer of the Royal Observatory, Cape Town. He received his earlier education in South Africa and graduated in arts at the Cape of Good Hope in 1877 with honours, being Maynard Scholar and University Exhibitioner. He then entered King's College, London, where he was Warneford Scholar, and later obtained a scholarship at Magdalene College, Cambridge. He did not proceed to the medical degree but qualified in 1883 as M.R.C.S. Eng., taking the L.R.C.P. Lond. two years later. In 1892 he obtained the F.R.C.S.Eng., and a little later the M.R.C.P. Edin. His life-work was associated with Portsmouth and the district, for it is over 30 years since he began to practise there, first as a general practitioner and later as an operating surgeon. The appointment with which his work was prominently associated was that of surgeon to the Royal Portsmouth Hospital, at which institution he was for some time the chairman of the committee of management, while he was senior consulting surgeon at his death. He was also surgeon to the Hants and Isle of Wight School for the Blind, and surgeon to the Southsea Home for Children, while outside his strictly medical activities he did splendid public service for Portsmouth as a sanitarian. In particular he took a prominent share, as chairman of the health committee of the corporation, in the improvement of housing conditions and the evacuation and clearing up of slum tenements.

During the last 20 years of his life Childe devoted much attention to the incidence and manifestations of cancer, and a small book which appeared in 1907 from his pen put the problems before the public in a really valuable manner. The book was an attempt to substitute sound knowledge and hope for ignorance and despair, and the constructive views with which it closed are to-day far less speculative than they appeared when written. He wrote in the *British Medical Journal* on the operative treatment of intra-oral cancer, in the *British Journal of Surgery* upon carcinoma of the cervix uteri, and to THE LANCET he made a notable contribution upon "acute abdominal conflux." How good an all-round surgeon he was is well illustrated by the classifications employed in this paper and the indications laid down for operation. In 1923 he was elected President of the British Medical Association, when he chose for his inaugural address the subject of Environment and Health, and dwelt forcibly on the need for concentration on the prevention of disease and on strengthening of resistance by the improvement of general social conditions.

We have lost in C. P. Childe one whose general knowledge and civic qualities made him a fine representative of the profession apart from his fine qualities as a surgeon.

---

## SAMUEL FLEMING, M.B., C.M. EDIN., D.P.H. CAMB.,

LIEUT.-COL., R.A.M.C., METROPOLITAN POLICE MAGISTRATE.

Samuel Fleming, whose recent death was announced, while only 60 years of age, was better known in his legal than in his medical capacity. The son of Mr. Frederick Fleming, he received his medical education at the University of Edinburgh, and after a successful career as a student graduated in 1890 as M.B., C.M., and after holding certain residential posts started as a general practitioner in Broadway, Worcestershire. From there he shortly after migrated to London and rapidly built up a practice in the Hornsey and Muswell Hill districts, becoming also a member of the district council and taking a prominent part in public affairs. The bent of his activities was further manifested when in 1897 he was called to the Bar and joined the North-Eastern Circuit. His double training he used with considerable advantage in medico-legal cases, and when he accepted the office of a metropolitan police magistrate he was in the enjoyment of considerable practice.

On the outbreak of war he joined the R.A.M.C., but his legal knowledge was promptly utilised by the authorities by his appointment as Legal Adviser and Judge Advocate to the Aldershot Command. From here he was transferred to the War Office as Legal Adviser to the Army Medical Department, being graded as D.A.D.G. in 1917 and receiving a brevet lieut.-colonelcy in 1918. After the war he was appointed Recorder of Doncaster and also became a member of the Bar Council. He resigned the Recordership on being made a police magistrate in 1921, and officiated first at Greenwich and Woolwich, being transferred last year to Lambeth. His death occurred on board ship when on a voyage to South Africa, undertaken partly to visit a married daughter, but partly in response to medical advice enjoining rest from the stress of work owing to his cardiac condition. He had, as a matter of fact, suffered from cardiac disorder for many years, though he had never allowed the disability to interfere with his career.

Dr. Fleming married in 1892 Elizabeth, the daughter of Colonel William Clare Ball, C.B., by whom he had three daughters; these and his widow surviving him.

Dr. F. J. McCann sends us the following personal tribute to his old friend:—

"Sam Fleming, for thus he was known to his many friends, was a popular medical student at Edinburgh University in the 'eighties. Endowed with a baritone voice of good range and quality he was in great demand at 'at homes,' 'kitchen concerts,' and the musical recitals which the late Sir Herbert Oakley gave when professor of music. His geniality and musical tastes formed a bond of union between us which remained unbroken for over 40 years. . . . Colonel Fleming was of medium height with a well-shapen head poised on broad shoulders. He was clean-shaven, with well-cut features. His rounded face was illuminated by greyish-blue eyes surmounted by prominent eyebrows, whilst his luxuriant hair, which in later years had become grey, added further distinction to his appearance. The genial smile and the merry twinkle in his large expressive eyes with which he greeted his friends added still further attraction to his personality. He possessed, probably more than most men, the capacity for making friends and retaining friendships, and was seen to greatest advantage when welcoming his friends at his home. Here he was ably supported by his wife, an exceptionally fine amateur pianist. But behind this geniality, this success, and this *joie de vivre* there lurked the spectre of cardiac disease. For many years he had suffered from a cardiac disorder which for a long time at least had nullified the prognostications concerning it. . . . Latterly, however, certain signs appeared which portended disaster, forcing him to slacken the pace. Attacks of cardiac pain and breathlessness on exertion caused him to realise that all was not well. A rest from work and a voyage to South America had produced a temporary amelioration, and it was thought a further holiday would be beneficial. He accordingly determined to go to South Africa to pay a visit to his daughter, but shortly after embarking on the voyage he had a severe anginal attack from which he recovered, but a few days later he succumbed to a second attack. He was buried at sea."

---

## JOHN CHADWICK, M.R.C.S. ENG.

Dr. J. Chadwick, the senior medical practitioner of the Rochdale district of Lancashire, died on Jan. 25th at his house in Milnrow within six days of his seventy-first birthday. In Milnrow, where his family has lived for over 300 years, he had practised for more than half a century. The son of a medical man, he received his early education at the Rochdale Grammar School; he then entered Owens College, Manchester, and qualified L.S.A. in 1877 and M.R.C.S. in 1888. From 1884 onwards he took an active interest in the public life of Milnrow, and in 1885 was elected first chairman of the local district council. In 1900 he resigned membership of the council to become medical officer of health for the district, a position which he continued to hold up to the time of his death. As medical officer of health he was very zealous in his work, and as his reports showed, there was plenty of scope for his endeavour. He served on the Lancashire County Council from 1898 onwards and was also a county alderman. As a member of the county council he acted on the Child Welfare, Public Health, Tuberculosis, Old Age Pensions, and Midwives Act Committees, and was also representative of the council on the Lancashire Asylums Board. Dr. Chadwick's unfailing kindliness and strong, vigorous character made him much respected as a practitioner. He had a retentive memory and was an excellent story-teller, especially in the Lancashire dialect. He was interested in agriculture and keen on golf and cricket. It had been the intention of a large number of friends to make a presentation of his portrait to Dr. Chadwick on the completion of his seventy-first year, and all arrangements had been made. He is survived by his widow and one sister.

---

## FRANK BOXALL, M.R.C.S. ENG., L.R.C.P. LOND.

THE death on Jan. 14th of Dr. Frank Boxall removes a familiar figure from West Sussex. Born in 1864 near Rudgwick, the village where he spent his life and his energies, son and brother himself of medical men, he was educated at University College Hospital and qualified in 1880, and after spells as obstetric assistant at his hospital and R.M.O. of St. Pancras Dispensary, he settled in Rudgwick and built up there a practice which he conducted single-handed for some 36 years, until his unexpected and rather sudden death. Throughout that period he rarely took a holiday, though he used to make time to attend, often at considerable distances and before the easy days of motors, branch or divisional meetings of the B.M.A. The most modest and unassuming of men, his life was a fine example of unselfish devotion to his patients and in accordance with the best traditions of the profession of medicine. Not only was he the friend of the countryside in sickness, in trouble, or in difficulty, but he was for some years chairman of the parish council and, ever a good churchman, churchwarden. The love and respect in which he was held was evidenced at his funeral by the crowded church, the neighbourhood of all classes mustering to pay their tribute to their trusted friend. He leaves a widow, two sons, and four daughters.

# Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia of the College was held on Jan. 28th, the President, Sir Humphry Rolleston, being in the chair.—The following were admitted to the Membership :—

Drs. Douglas K. Adams, George A. Allan, John F. Anderson, George V. Ashcroft, Hugh Barber, Harry Bedingfield, John A. Birrell, Ernest Bulmer, Ernest W. H. Cruickshank, Manindranath De, Henry B. F. Dixon, Daniel M. B. Evans, William M. Feldman, Gwenvron Mary Griffiths, Arthur H. Hall, John T. Ingram, Leslie M. Jennings, Frank A. Knott, Robert Knox, David Krestin, Alexander Lyall, Thottakat Bhaskara Menon, Trevor Owen, Albert E. H. Pinch, George H. Rossdale, Percy S. Selwyn-Clarke, George Simpson, Byron L. Stanton, Alexander J. H. Stobo, Selwyn E. Tanner, John T. P. Tansey, Norman B. Williamson, and Claude Wilson.

On the nomination of Council, Dr. James Collier, Dr. S. W. Wheaton, Dr. J. S. Fairbairn, and Dr. C. J. Martin were elected Councillors to take the place of Dr. W. S. Lazarus-Barlow, Sir John Broadbent, Dr. T. W. Eden, and Sir George Newman.—The President consulted the College as to the desirability of appointing an Assistant Registrar, and Dr. R. O. Moon was nominated for appointment at the next meeting.—Licences to practise were conferred upon 181 candidates (including 37 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the necessary by-laws. The following are the names and medical schools of the successful candidates :—

P. W. A. Agnew, St. George's; S. A. Antoun, Birmingham; N. A. Arnold, Guy's; A. Ashworth, Liverpool; A. L. Banks, Middlesex; C. M. Barker, Univ. Coll.; L. H. Belcher, Guy's; R. J. L. Bell and S. B. Benton, St. Bart.'s; S. Bernstein and M. Bomze, Univ. Coll.; Elsie Boyton, King's Coll.; R. Broomhead, Leeds; A. Byrne-Quinn, St. Thomas's; Irene F. Callender, St. Mary's; A. L. Canby, St. Thomas's; De Lisle Carey, St. Mary's; S. Chazen, Guy's; R. Childs, St. Thomas's; J. H. Chitty, Guy's; J. H. Clapp, London; A. Clark, St. Bart.'s; G. C. W. Clarke, Sheffield; H. N. Collier, Guy's; Violet H. Comber, Univ. Coll.; R. V. Cooke, Bristol; W. F. Cooper, St. Bart.'s; A. R. Cox, Guy's; S. T. Davies, Univ. Coll.; T. W. Davies, Cardiff; T. E. Davies, St. Thomas's; Hilda C. Dean, Charing Cross; A. E. de Fonseka, Ceylon and King's Coll.; May W. de Livera, Ceylon and Royal Free; G. C. Dewes, St. George's; H. V. Dicks, St. Bart.'s; Mary G. H. Dickson, King's Coll.; Margaret H. Duncan, London; G. H. Dymond, St. Bart.'s; Elaine O. H. Earengey, Univ. Coll.; R. W. B. Ellis, St. Thomas's; D. C. M. Ettles and J. Evans, Guy's; B. Fink, Manchester; C. W. Flemming, Univ. Coll.; T. D. W. Fryer, St. Thomas's; S. W. Gabbe, Cape and St. Thomas's; S. C. Gawne, Liverpool; P. Gibbin, Cardiff; Dorothy Godden, St. Mary's; P. J. Gonsalves, Guy's; D. P. A. P. Gorham, Bristol; Agnes H. Gray, Royal Free; D. P. Gray, Middlesex; Margaret K. Green, St. Mary's; W. H. Green, Middlesex; C. R. M. Greenfield, St. Bart.'s; L. A. N. Greenway, Calcutta and King's Coll.; B. J. Griffiths, Cardiff; A. A. M. Groot, Leyden and Westminster; A. Gross and F. P. Guilfoyle, St. Bart.'s; K. H. Hadley, Melbourne and Middlesex; R. N. Hall, St. George's; C. W. Harrison, St. Bart.'s; L. Hartston, London; H. G. Harvey, St. Thomas's; J. P. Helliwell, St. Mary's; T. R. Hill, Guy's; R. L. Holt, Manchester; B. B. Hosford, St. Bart.'s; Mary H. M. Huggett, King's Coll.; N. C. Hypher, London; D. E. Iago-Jones, Cardiff and Middlesex; R. J. Isaac, St. Mary's; G. L. C. Jones, Cardiff and St. Bart.'s; T. Jones, Cardiff; J. Kahanas, Berne and London; J. A. Kerr, Birmingham; Hilda M. King, St. Mary's; R. H. Knight, St. Bart.'s; P. H. Knowles, Bristol and St. Mary's; T. P. Lalonde, Bristol; F. J. L. Lang, St. Mary's; F. W. Law, Cambridge and Middlesex; D. F. Lawson and R. L. J. Le Clezio, St. Thomas's; Margaret E. Ledger, Royal Free; Anne Theresa Leigh, Manchester; E. A. Lewis, St. George's; R. A. V. Lewys-Lloyd, St. Bart.'s; Leonora M. K. Lines, Charing Cross; T. M. Ling, St. Thomas's; Edith M. Little, Royal Free; G. F. H. McCormick, Middlesex and Univ. Coll.; G. L. M. McElligott and L. J. McGregor, St. Thomas's; Evelyn T. D. Maclagan, St. Mary's; A. J. McMillan, Middlesex; P. Malpas, Liverpool; Ruth E. Mansfield, Westminster; Mary A. Marshall, St. Mary's; I. O. Martin, Cardiff; S. R. Matthews, Middlesex; H. R. R. Mavor, St. Thomas's; W. Mayne, Guy's; S. Mellins, Middlesex; R. H. Metcalfe, St. Thomas's; G. C. Milner, London; J. Mintzman, Middlesex; F. E. Montague, St. Thomas's; P. Morton, London; M. Mundy, St. Bart.'s; D. H. P. M. Q. Mylechreest, St. Thomas's; C. B. Nicholson, Middlesex; J. R. P. Norman, Birmingham; G. F. Oakden, Cambridge and St. Thomas's; E. J. O'Keeffe, N.U.I. and London; J. E. J. Palser and C. H. Parker, London; G. E. G. Peirce, St. Mary's; H. A. Picton, Birmingham; H. P. Pieris, Middlesex; N. R. Pooler, St. Mary's; W. G. Porter, Guy's; D. C. Price, St. Bart.'s; Winifred E. Probert, Cardiff and Westminster; D. M. Pryce, St. Mary's; Muriel A. Pugh, Charing Cross; F. W. F. Purcell, Cape and St. Thomas's; Nellie L. Pyman, Charing Cross; J. H. Randall, Univ. Coll.; Marjorie D. Reddan, Royal Free; Margaret G. P. Reed, King's Coll.; H. G. St. M. Rees, Cardiff; J. L. Reeve, St. Bart.'s; A. M. Rhydderch, London; O. Richardson, St. Bart.'s; L. Roberts, Middlesex; Victoria A. Roberts, Royal Free; D. J. L. Routh and Audrey E. Russell, Univ. Coll.; J. W. Schabort, Guy's; Gitta Schewel, Westminster; F. L. G. Selby, St. Mary's; T. H. Sellors, Middlesex; D. W. Seth-Smith, St. George's; A. de M. Severne, St. Thomas's; W. D. Sheldrake, Guy's; M. Sidky and H. J. A. Simmons, Middlesex; W. S. Slater, Manchester; E. V. Slaughter, Middlesex; Beatrice G. Smith, Univ. Coll.; L. G. Smith, St. Bart.'s; A. Sourasky. Leeds; H. B. Stallard, St. Bart.'s; C. A. Stanley, St. Thomas's; B. L. Steele, Univ. Coll.; A. F. H. Stewart, Guy's; R. K. Stockbridge, Adelaide and London; Dorothy S. Tait, St. Mary's; G. M. Tanner, St Bart.'s; Constance P. Thomas, Cardiff; D. W. R. Thomas, Cardiff and Middlesex; R. Thorpe, St. George's; G. O. Tippett, St. Thomas's; R. S. Tooth, St. Bart.'s; Rose A. H. Traill, Charing Cross; R. M. Walker, Univ. Coll.; L. H. F. Walton and H. D. Weatherhead, St. Thomas's; Janet Welch and Violet M. Weston, Royal Free; E. A. White, St. Bart.'s; J. E. B. Williams, Univ. Coll.; J. H. Williams, Cardiff; H. Williamson, King's Coll.; D. B. Wilson, Cambridge and Birmingham; Jessie Wiltshire and Ada R. Winter, Univ. Coll.; J. Wiseman, Guy's; Joan Worsfold, Royal Free; and Dorothy E. Wright, Univ. Coll.

The special diplomas mentioned in the report of the Council of the Royal College of Surgeons of England were also conferred (jointly with that College) upon the candidates whose names were specified in THE LANCET of Jan. 23rd. In addition the Diploma in Ophthalmic Medicine and Surgery was conferred upon the following candidates :—

Esme V. Anderson, J. B. Baird, A. Bajaj, D. P. Billimoria, C. H. G. Blakemore, Victoria E. Brander, J. A. Browne, A. Caddy, H. R. Dive, R. R. Garden, P. N. Gokhale, G. McN. Hargreaves, K. R. Hill, A. MacRae, J. Marshall, J. N. Piplani, Portia K. Taylor, Doris Todd, and S. T. Wong.

Dr. Major Greenwood moved the following resolution :—"The College, taking note of the fact that members of the medical profession have stated in the public press that the practice of certain methods of diagnosis and treatment generally known as 'Psycho-analysis' is open to grave objections, requests the President to appoint a committee to inquire into the truth of such allegations, so far as they relate to the practice of members of the medical profession, and to report what restrictions, if any, it may be in the public interest to impose upon the use of these methods by Fellows, Members, and Licentiates of the College." This was not carried.—Sir Francis Champneys was appointed, on the nomination of the Council, as a representative of the College on the Central Midwives Board.—Dr. Drewitt was reappointed representative of the College on the Committee of Management of the Chelsea Physic Garden for four years.—Sir Thomas Barlow was reappointed a representative of the College on the Executive Committee of the Imperial Cancer Research Fund.—Dr. Arthur Shadwell was appointed a representative of the College on the Queen Victoria Jubilee Institute for Nurses.—The President announced that he had appointed Dr. F. G. Crookshank to deliver the Bradshaw Lecture for 1926, and that the Council have appointed Mr. W. F. Dearden to be Milroy Lecturer for 1927.—The resignation of Mr. Bryan Farrer as junior standing counsel to the College was received. The President nominated Mr. Dighton Pollock for election. It was directed that a letter should be sent to Mr. Bryan Farrer thanking him for services of quarter of a century.—The resignation of Sir Dyce Duckworth as Representative Governor of the University of Liverpool was received. The Council expressed their high sense of the services he has rendered. Dr. Abram was appointed in his place.—The Registrar moved for the first time that By-law 160 be amended to read as follows :—

"A list of all Fellows and Members of the College, and a list of the new licentiates and diplomates in the special branches of medicine admitted during the preceding 12 months, with their places of residence, shall be printed annually under the direction of the Censors' Board, and a copy of such lists certified under the College seal shall be sent to the registrar of the branch medical councils for England, Scotland, and Ireland."

The report of the representative of the College on the General Medical Council on the proceedings of the Council at its session held in November last was received.—Books and other donations to the Library presented during the last quarter were received and thanks returned to the donors.

The following reports from the Committee of Management, dated Dec. 23rd, 1925, were received and adopted :—

1. The Committee of Management recommend that certain universities which were removed in the year 1918 from the list of recognised places of study, and graduates of which are admissible to the Final Examination of the Board, be now reinstated in the list, as follows :—*Austria:* Graz, Innsbruck, Vienna. *Czecho-Slovakia:* Prague. *Germany:* Berlin, Bonn, Breslau, Erlangen, Freiburg, Giessen, Gottingen, Greifswald, Halle, Heidelberg, Jena, Kiel, Königsberg, Leipzig, Marburg, Munich, Tübingen, Würzburg. *Hungary:* Budapest. The Committee also recommend that the University of Hamburg be added to the list of recognised German universities.

2. The Committee of Management recommend that the following additional clauses be added in Chapter I. of the Regulations of the Examining Board in England: X. Any representation which a candidate may desire to make with regard to the conduct of his examination must be addressed to the secretary

and not, under any circumstances, to any of the examiners. XI. The Committee of Management may refuse to admit to examination or to proceed with the examination of any candidate who infringes a regulation of the Examining Board in England, or is considered by the Committee to be guilty of behaviour prejudicial to the proper management and conduct of the Examination.

3 In accordance with the conditions relating to special diplomas laid down by the Royal Colleges in April, 1920, the Committee of Management now report that they have recognised courses of instruction at the following institutions :—D.P.H. : Newport Borough Isolation Hospital (fever hospital practice). D.T.M. & H. : Royal Army Medical College (laboratory course). D.O.M.S. : Cork Eye, Ear and Throat Hospital (complete courses). D.P.M. : Bethlem Royal Hospital (neurology, pathology, and bacteriology). D.L.O. : Royal Naval Hospitals at Chatham, Haslar, and Plymouth (hospital practice only under special conditions). Norfolk and Norwich Hospital (hospital practice only).

The Comitia was constituted into an extraordinary Comitia and, on a report from the Censors' Board, it was resolved : "That Charles Bertrand Wagstaff be declared to be no longer a Licentiate of the College ; that he forfeit all the rights and privileges of a Licentiate ; and that his name be expunged from the List of Licentiates—during the pleasure of the College."

After some formal College business the President dissolved the Comitia.

**Society of Apothecaries of London.**—At recent examinations the following candidates were successful in the undermentioned subjects :—

*Surgery.*—E. W. D. Long, London Hosp. ; P. B. B. Mellows, St. Bart.'s Hosp. ; D. P. Mitra, Charing Cross Hosp. ; M. N. Nicolson, Sheffield ; and G. H. Pereira, St. George's Hosp.

*Medicine.*—C. H. S. Johnston, Birmingham ; P. H. L. Moore and G. H. Pereira, St. George's Hosp. ; and B. A. Perott, Petrograd.

*Forensic Medicine.*—W. Hinds, Durham ; and M. Pettigrew, Sheffield.

*Midwifery.*—M. Bannounah, Guy's Hosp. ; W. H. D. Priest, King's Coll. Hosp. ; L. A. Rostant, St. Thomas's Hosp. ; and J. W. Whitney, London Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery : M. Bannounah, E. W. D. Long, P. B. B. Mellows, and B. A. Perott.

**University of London.**—A meeting of the Senate was held on Jan. 27th, Prof. E. A. Gardner, the Vice-Chancellor, being in the chair. The Doctorates conferred include the following :—D.Sc. in Psychology : Mr. E. H. Magson, of University College, for a thesis entitled How We Judge Intelligence. D.Sc. in Cytology : Mr. R. J. Ludford, for a thesis entitled Studies in Normal and Pathological Cytology, and other papers. Dr. Andrew Balfour and Dr. M. E. Delafield were appointed to represent respectively the University and University College at the Imperial Congress of the Royal Sanitary Institute to be held in London in July to celebrate the jubilee of the Institute.

Applications are invited for the Graham scholarship, value £300, founded by the late Dr. Charles Graham to enable a young man to continue his pathological researches, his services remaining under the direction of the Professor of Pathology at University College. Applicants, who need not be students of the University medical schools, should send in their names before March 1st. Further particulars may be obtained from the Academic Registrar of the University.

**Fellowship of Medicine and Post-Graduate Medical Association.**—On Feb. 11th Dr. S. A. Kinnier Wilson will lecture for the Fellowship on Sudden Cerebral Lesions, at 5 P.M., in the lecture hall of the Medical Society of London, 11, Chandos-street, W. This lecture is free to members of the medical profession. The Queen Mary's Hospital, Stratford, will give a general intensive course in medicine, surgery, and the special departments from Feb. 15th to 27th. Daily sessions will be held from 10 A.M. to 5 P.M. (excepting Mondays, when they begin at noon), including demonstrations of clinical methods and groups of illustrative cases. There will be opportunities for those attending the course to visit the new gynæcological and obstetrical department at this hospital. Courses in progress are a combined course in Diseases of Children at Paddington Green Hospital, Victoria Hospital, and the Children's Clinic, and a comprehensive course in Venereal Diseases at the London Lock Hospital. For the convenience of general practitioners the London Temperance Hospital will hold a general course from 4.30 to 6 P.M. in the various departments of the hospital from Feb. 8th to 19th. The March courses are as follows : Bacteriology, diseases of the chest, gynæcology, ophthalmology, tropical medicine, and a course for general practitioners. Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

**West Kent Medico-Chirurgical Society.**—A meeting of this society will be held at the Miller General Hospital, Greenwich, S.E., on Friday, Feb. 12th, at 8.15 P.M., when Dr. Millais Culpin will give an address entitled the Scope of Psychotherapy.

**Hunterian Society.**—The annual dinner of the society will be held at the Hotel Victoria, Northumberland-avenue, on Thursday, Feb. 11th, at 7.30 P.M. The Lord Mayor and Lady Mayoress of London and the Bishop of Kensington will be amongst the guests. Fellows wishing to be present are asked to write to Mr. Mortimer Woolf, 91, Harley-street, London, W. 1.

**The Rogers Medical Prize Essay.**—Nearly 10 years ago Dr. Joseph Rogers, Chairman of Council and Vice-President of the Poor-law Medical Officers' Association, left £500 in trust for the establishment of an essay competition, the money to accumulate until the sum in hand sufficed to provide a prize of £150, for the best essay on the Treatment of the Sick Poor of the Country and the Preservation of the Health of the Poor. The first award will be made on June 21st, the anniversary of the death of Dr. Rogers's widow. The trustees are the President of the Royal College of Physicians of London and the Master of the Society of Apothecaries, and the prize will be competed for every ten years.

**Paris Faculty of Medicine.**—A revision and post-graduate course on Recent Views of Clinical Practice and the Use of Current Laboratory Methods in Diagnosis is to be given at the Medical Clinic of the Hôtel-Dieu from March 22nd to April 2nd, under the direction of Prof. Maurice Villaret. There will be 36 lessons, and they will be so arranged as to give students a chance of seeing something of the hospital work of Paris in the intervals. Further information may be obtained from the Secretary of the Faculty of Medicine of the University of Paris. Afternoon courses in Dermatology and Syphilology are held at the Hôpital St. Louis under the direction of Prof. M. Jeanselme. The next course in dermatology will begin on April 12th and in Venereal Diseases on April 17th. Details of these can be obtained from Dr. Burnier, Hôpital St. Louis, Paris.

**Lancashire Hospitals for Crippled Children.**—The Lancashire County Council is asked to approve a proposal to establish a new tuberculosis hospital at Wrightington Hall, near Parbold, where it is proposed to provide 80 beds for adults and 110 for children in five new pavilions, leaving the hall, after suitable changes, as the administrative block. The Ministry of Health has agreed, subject to the approval of the Treasury, to make a grant of £180 per bed towards the capital cost. The Council has also been recommended by its finance committee to apply for sanction to a loan of £25,000 to meet the cost of buying the Biddulph Orthopædic Hospital, North Staffordshire, for the treatment of crippled school-children.

**Birth Control Clinic for Manchester and Salford.**—It is announced that a Manchester and Salford mothers' clinic is shortly to be established, probably with its headquarters in Salford. A woman doctor has been appointed to conduct the work and the necessary funds have so far been obtained by private subscription. The services of the clinic will be available only for women who are already mothers. The promoters aim at providing a channel through which married women, whose means are insufficient to enable them to command the services of a private practitioner, may obtain, under expert medical direction, knowledge of the best known methods of contraceptive birth control. The Ministry of Health does not at present allow this instruction to be given at the existing maternity and infant welfare centres.

**The late Dr. W. C. Cooke.**—After a long illness Dr. William Conway Cooke died on Jan. 20th at the age of 76. A son of the late Rev. Canon Daniel Cooke, of Rochester, Kent, Dr. Cooke studied medicine at King's College Hospital, London, and qualified as M.R.C.S. Eng. in 1875 and L.R.C.P. Edin. two years later. In 1878 he settled at Bognor, where he joined the late Dr. Whitman Thompson in partnership. Later he entered practice on his own and became medical officer of health, holding the office for the long period of 32 years. Some five years ago he resigned owing to ill-health. Dr. Cooke was appointed to this important post when Bognor was a small fishing village, and that the town has now developed into a flourishing seaside resort is no doubt in a great measure due to the care he exercised. In 1895 Dr. Cooke entered into partnership with Dr. F. S. Tidcombe, and they built up a very large practice, not only in Bognor itself but in the district round. During the war Dr. Cooke was a major in the R.A.M.C. (T.). He leaves a widow and a daughter.

**LEICESTER ROYAL INFIRMARY.**—It is hoped to rebuild the central wing of this institution at a cost of £40,000, of which only £12,000 has yet been obtained. An anonymous offer of £10,000 has now been made on condition that the balance of £18,000 is raised without recourse to invested funds.

AN international post-graduate medical course will be held, with special reference to balneology and balneotherapy at Karlsbad on Sept. 12th–18th. Special railway concessions are being offered to foreign doctors. Further information can be obtained from Dr. Edgar Ganz, Karlsbad.

**LONDON TEMPERANCE HOSPITAL.**—This hospital is in such serious difficulties that the board of management state that unless generous support is forthcoming they will have to consider seriously whether it shall be closed. Last year ended with a deficit of £26,000, caused to a great extent by compulsory extraordinary expenditure.

**ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.**—The next quarterly meeting of this association will take place on Feb. 16th at 19B, Tavistock-square, London, W.C. (British Medical Association House), under the presidency of Sir Frederick Mott, F.R.S., at 2.30 P.M. Dr. Isabel Robertson will read a paper entitled "Blood and Vascular Conditions in Psychoses."

**THE LATE DR. VERNON HOWARD.**—Dr. E. V. Howard, who died in London on Jan. 18th, was a graduate in arts, letters, and medicine of the University of Durham, where he qualified M.B., B.S. in 1921. For a time he acted as house surgeon at the Eye Infirmary, Newcastle, and in April last was appointed medical officer and public vaccinator for the Benington district under the Boston Board of Guardians. Besides holding the appointment he was engaged in private practice in this district of Lincolnshire.

**LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.**—Nearly 200 past and present students assembled on Jan. 28th at the School to meet Dr. F. Wood Jones, F.R.S., now professor of anatomy in the University of Adelaide, who was on a brief visit to this country. Prof. Mary Lucas Keene, on behalf of the staff and past students, expressed the pleasure felt at seeing him again at the School, and recalled the seven happy years during which he had worked among them as colleague and teacher. Prof. Jones then gave a lecture on the Theories of Evolution.

**ROYAL SANITARY INSTITUTE.**—A sessional meeting will be held on Friday, Feb. 26th, in the Municipal Buildings, Middlesbrough, from 4 P.M. onwards. There will be discussions on the Malthriving Infant, the Present Type of Small-pox, Organic Salvage, and Housing and Main Drainage, and on the following day there will be an opportunity to visit works of sanitary interest in the neighbourhood. The first two discussions will be opened by Dr. Grace Dundas and Dr. C. V. Dingle respectively. Those intending to be present should notify the hon. local secretary, Mr. S. E. Burgess, city engineer and surveyor, not later than Feb. 20th.

**MIDDLESEX HOSPITAL ANNEXE.**—From Feb. 12th to the 14th the temporary premises of the Middlesex Hospital, which have been formed out of an old M.A.B. infirmary in Cleveland-street (near the hospital) will be on view prior to their opening by the Minister of Health on Feb. 23rd. The opening of the annexe is described as the first step towards the reconstruction of the Middlesex, and as the processes of pulling down and rebuilding are likely to last for several years the temporary home has been made complete in itself. From top to bottom the building has been re-floored, drained, heated, and lighted according to modern standards of hospital design. There are six wards, two operating theatres, and an X ray department, and about 180 patients will be moved into the building before the opening.

**ST. THOMAS'S HOSPITAL.**—The ballot designed to help the funds has actually resulted in a loss to the hospital of more than £1000. Holders of half-crown tickets were asked to place in order of popularity 12 out of a list of 24 sportsmen, and it was hoped that half a million tickets would be sold. Actually only about 250,000 were disposed of, and Mr. G. Q. Roberts, the secretary, believes that the competition was too difficult. Large sums were spent upon advertising, and during the competition two other ballots, with even larger prizes, were announced. The winner of the first prize of £5000, a lady employed in the Post Office Savings Bank Department, has given a donation of £500 and has been elected a governor, and the winner of the touring car, which formed the second prize, a woman shop assistant, has promised to return 10 per cent. of the amount for which she sells it.

**NORTHAMPTONSHIRE** men and women in London are requested to get into touch with an organisation which arranges social gatherings for them. The secretary is Mr. J. H. Woolgar, 1, Dorset-buildings, E.C. 4.

**PRESENTATION TO DR. ESSEX WYNTER.**—Sir John Bland-Sutton presided over a gathering of old Middlesex Hospital men at Prince's Restaurant on Jan. 28th, when Dr. Essex Wynter's friends entertained him to dinner on his retirement from the active staff of the Middlesex Hospital. Dr. Wynter was presented with a portrait of himself, painted in oils by Miss Beatrice Bright, which was the gift of over 140 subscribers.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Opening of the Session.—The King's Speech.*

THE new session of Parliament was opened by the King in State in the House of Lords on Feb. 2nd. In the course of His Majesty's gracious speech from the Throne it was stated that invitations were being issued to the Governments of Belgium, France, Germany, and Italy to attend a conference in London to consider the possibility of securing an effective international agreement for regulating hours of labour. The Government had given earnest consideration to the increasing need for national economy. Proposals for effecting reductions of public expenditure were now being formulated and the House of Commons would be asked to pass measures required to give effect to them without delay.

While His Majesty had learned with satisfaction of the progress made in the building of new houses in the urban areas of England and Wales, the conditions under which many of the people were compelled to live, both in country districts and in the congested areas of numerous towns, still occasioned him deep concern. His Ministers were now examining certain proposals for the improvement of these conditions, and if time permitted they would submit to Parliament measures designed to hasten the removal of the worst defects, both in town and country. Among the Bills which would, if time and opportunity permitted, be laid before Parliament in the coming session were measures dealing with National Health Insurance, the control of road vehicles, the finance of Poor-law in London, and the position and powers of boards of guardians, and the rating and valuation machinery in Scotland.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham N.

Monday, Feb. 8th.—10 a.m., Surgical Out-patients: Mr. W. E. Tanner. 10.30 a.m., *Gynæcological* Operations: Mr. A. E. Giles: Throat, Nose and Ear Operations: Mr. W. *Ibbotson*. 2 p.m., Medical, Surgical, and Gynæcological Clinics, Operations. 6.30 p.m., Venereal Department.

Tuesday.—2 p.m., Medical, Surgical, *Throat*, Nose and Ear Clinics, Operations. 4.30 p.m., Mr. E. Gillespie: The Diagnosis and Treatment of Cancer of the Breast.

Wednesday.—10.30 a.m., Surgical Operations: Mr. E. Gillespie. 2 p.m., Medical, Eye, and Skin Clinics, Operations. 6.30 p.m., Venereal Department.

Thursday.—10.30 a.m., *Dental* Out-patients: Mr. E. S. Pierrepont. 2 p.m., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 p.m., Operations.

Friday.—10 30 a.m., Eye Operations: Mr. N. Fleming. 2 p.m., Surgical, Medical, and Children Clinics, Operations. 3 p.m., Gynæcological Clinic. 6.30 p.m., Venereal Department.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn road, W.C.

Friday, Feb. 12th.—4 p.m., Mr. Archer Ryland: Musculature of the Vocal Cords.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

Tuesday, Feb. 9th.—5 p.m., Dr. Graham Little: Lichen Planus.

Thursday.—5 p.m., Dr. A. C. Roxburgh: Scleroderma, Neurofibromatosis.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.

Wednesday, Feb. 10th.—5.30 *p.m., Mr. C. B. Henry*: Radiographic Appearances of Chronic Periodontal Infections.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, *Queen square, Bloomsbury*, W.C. 1.

POST-GRADUATE COURSE: February–March, 1926.

Clinical Lectures and Demonstrations.

Monday, Feb. 8th.—2 p.m., Out-patient Clinic: Dr. Hinds Howell. 3.30 p.m., Paraplegia: Dr. Risien Russell.

Tuesday, Feb. 9th.—2 p.m., Out patient Clinic: Dr. Walshe. 3.30 p.m., Disseminated Sclerosis, II.: Dr. Grainger Stewart.

*Thursday, Feb. 11th.—2 p.m., Out-patient Clinic: Dr.* Kinnier Wilson. 3.30 p.m., Some Effects of Spinal Injury: Dr. Gordon Holmes.

Friday, Feb. 12th.—2 p.m., Out-patient Clinic: Dr. Adie. 3.30 p.m., Demonstration of Re-educative Exercises (in Exercise Room): Mr. Elmquist.

The fee for the Course, including Pathology lectures, is £5 5s. *For those who hold Perpetual Tickets the fee is £3 3s.*

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Monday, Feb. 8th.—12 noon, Axon: *Dr. J. G. Greenfield.*

Dr. F. M. R. Walshe will give Eight Lectures on The Anatomy and Physiology of the Nervous System at 12 noon on Thursdays if there are sufficient applicants. The Fee for this Course will be £2 2s.

*Dr.* H. J. Macbride will give a Course of Eight Clinical Demonstrations, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 a.m. on Tuesdays and Fridays if sufficient entries are received. The fee for this Course will be £2 2s. (Commencing Feb. 16th.)

Mr. Armour and Mr. Sargent operate at the Hospital on *Tuesday and Friday mornings at* 9 a.m. or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

*Fees* should be *paid to the Secretary* of the *Hospital* at the Office on entering for the Course.

*J. G. Greenfield, Dean* of Medical School.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

Thursday, Feb. 11th.—4.15 p.m., Dr. Charles Singer: The *History of Gout and Diabetes* (second of four lantern lectures, open to medical students of the University of London).

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.

Wednesday, Feb. 10th.—Dr. Harrison: Chemical Tests in Acidosis.

Thursday.—4 p.m., Dr. Poynton: Upon the Early *Diagnosis* of Tuberculosis.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

*Thursday*, Feb. 11th.—5 p.m., Mr. L. G. *Phillips*: Management of Contracted Pelvis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.

Tuesday, Feb. 9th.—3.30 p.m. (at the *South Yorkshire* Asylum), Dr. Vincent: Early Diagnosis of Mental Cases.

Friday.—3.30 p.m. (at the Royal Infirmary), Mr. Cuff: *Surgical Clinical Cases.*

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE.

Friday, Feb. 12th.—4.30 p.m. *(at* Whitworth-street West Branch), Dr. C. P. Lapage: Convulsions in Infancy *and Childhood.*

## Appointments.

Bigland, A. D., M.D., Ch.B. Liverp., has been appointed Visiting *Physician at the* Broadgreen Hill Infirmary, Liverpool.

Griffiths, G. Mary, M.D., M.R.C.P. Lond., Assistant Medical Officer, Cheddleton Mental Hospital, Staffordshire.

Guy, J. B. S., M.B., B.S. Durh., Certifying Surgeon under the Factory and Workshop Acts for the Loftus District of the County of York.

St. Mary's Hospitals, Manchester: Adam, R. S., M.B., Ch.B. Manch., Meacham, G. L., M.B., Ch.B. Manch., Edwards, N., F.R.C.S., Stenhouse, G., M.B., Ch.B. Manch., and Humble, E. Greta, M.B., Ch.B., House Surgeons.

## Vacancies.

*For further information refer to the advertisement columns.*

*Ashton-under-Lyne, District Infirmary.*—H.S. At rate of £150.

*Barnsley, Beckett Hospital and Dispensary.*—Jun. H.S. £140.

*Bath, Eastern Dispensary.*—Res. M.O. £175.

*Birkenhead Borough Hospital.*—Two H.S.'s. £200 and £150 respectively.

*Birmingham General Hospital.*—Part-time Clin. Asst. in Ven. Dept. £350.

*Birmingham, Highbury Group of Hospitals.*—Jun. Surg. O. £350.

*Bolingbroke Hospital, Wandsworth Common, S.W.*—Res. M.O. £200. Also H.S. At rate of £120.

*Bradford City.*—Asst. Bacteriologist. £600.

*Bradford, Municipal General Hospital, St. Luke's.*—H.P.'s and H.S.'s. Each at rate of £200.

*Bristol Royal Infirmary.*—Hon. S.

*Carlisle, Cumberland Infirmary.*—H.P. At rate of £135. Also Jun. H.S. At rate of £135.

*Chesterfield and North Derbyshire Royal Hospital.*—Fifth H.S. At rate of £100.

*Dorset Mental Hospital, Herrison, near Dorchester.*—Deputy Med. Supt. and Pathologist. £575.

*East London Hospital for Children and Disp. for Women, Shadwell, E.*—S. for Nose, Throat and Ear.

*Hampstead General and North-West London Hospital, Haverstock-hill, N.W.*—H.P. Also Cas. M.O. Each at rate of £100.

*Holloway Sanatorium, Virginia Water, Surrey.*—Med. Supt. £1600.

*Hospital for Consumption and Dis. of Chest, Brompton, S.W.*—Æmæsthetist.

*Leeds City.*—Chief Clin. Tuberculosis O. £1000.

*Leeds Public Dispensary.*—Sen. Res. M.O. £200.

*Liverpool Open-Air Hospital for Children, Leasowe, Cheshire.*—Res. Jun. M.O. £200.

*London Lock Hospital, 91, Dean-street, W.*—Surg. Reg. £100.

*Manchester, Ancoats Hospital.*—Res. M.O. Also H.S. At rate of £150 and £100 respectively. Also Anæsthetist. 10s. 6d. per attendance.

*Manchester Royal Infirmary.*—Hon. Asst. P. to Out-Patients.

*Manchester, St. Mary's Hospitals.*—Res. Obstet. O. and Res. Surg. O. Each £200.

*Manor House Hospital, Golders Green, N.W.*—H.S. £200.

*Margate, Princess Mary's Hospital for Children.*—Second Asst. M.O. £550.

*Northampton County Mental Hospital, Berry Wood.*—Sen. Asst. M.O. £500.

*Northampton General Hospital.*—Third H.S. At rate of £150. H.P. and H.S. Each at rate of £150.

*Northern Hospital, Winchmore Hill, N.*—Asst. M.O. for Encephalitis Lethargica Unit. £550.

*Royal Free Hospital, Gray's Inn-road, W.C.*—Second Asst. to Venereal Diseases Clinic.

*Royal Northern Hospital, Holloway, N.*—Cas. O. At rate of £90.

*Royal Waterloo Hospital for Children and Women, Waterloo-road S.E.*—Part-time Pathologist. £200.

*St. Mary Abbots Hospital, Marloes-road, Kensington.*—Asst. M.O. £326 17s.

*St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.*—H.S. At rate of £75.

*Salford Royal Hospital.*—Radiologist. £300. Also Hon. Gynæcologist and Hon. Asst. Gynæcologist.

*Salford Union Infirmary, Hope, Pendleton, near Manchester.*—Two Asst. Res. M.O.'s. £300 and £375 respectively.

*Shrewsbury, Royal Salop Infirmary.*—H.P. £160.

*West Bromwich and District Hospital.*—Res. H.S. £220.

*West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.*—Sen. H.P. At rate of £150.

*West London Hospital, Hammersmith, W.*—Asst. Path. £250.

*Western Skin Hospital, 44-46, Hampstead-road, N.W.*—Hon. Radiologist.

The Home Secretary announces a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Districts of the Bradford, Keighley, Settle, and Skipton County Courts (Circuit No. 12). Applications should reach the Private Secretary, Home Office, not later than Feb. 24th.

# Births, Marriages, and Deaths.

## BIRTHS.

LINDSAY.—On Jan. 22nd, at The Circus, Bath, the wife of James Lindsay, M.D., M.R.C.P., of a son.

MECREDY.—On Jan. 22nd, at Lower Baggot-street, Dublin, to Dr. and Mrs. Gerald Mecredy—a daughter.

PARRY.—On Jan. 25th, at King's-avenue, Muswell Hill, the wife of Reginald G. Wolfe Parry, L.D.S. Eng., of a son.

TOWNROW.—On Jan. 23rd, the wife of Vincent Townrow, F.R.C.S., Ivy Park-road, Sheffield, of a daughter.

## MARRIAGES.

BAILEY—WIBLIN.—On Jan. 21st, at St. Peter's, Regent-square, W.C., Kenneth Norman Grierson Bailey, M.B., B.S. Lond., to Nellie, younger daughter of the late J. G. Wiblin and Mrs. Wiblin.

WALL—MCGREGOR.—On Dec. 10th, 1925, at St. John's Cathedral, Hong-Kong, by Rev. T. B. Powell, Margaret Alice, daughter of Charles Malcolm and Mrs. McGregor, of Plumstead, S.E., to Austin Darley Wall, M.B., F.R.C.S., of Shanghai, China.

## DEATHS.

BROWNE.—On Jan. 29th, at Carlton-road, Weymouth, Dr. Thomas Browne, R.N., Inspector-General of Hospitals and Fleets, aged 84.

BURKE.—On Jan. 29th, Ulick, second son of Dr. and Mrs. E. T. Burke, of Manchester. Service took place at the Manchester Crematorium on Jan. 31st.

CHILDE.—On Jan. 29th, at Monte Carlo, of heart failure following pneumonia, Charles Plumley Childe, B.A. Camb., F.R.C.S. Eng., M.R.C.P. Edin., of Cranleigh, Kent-road, Southsea.

GERATY.—On Jan. 20th, at Waverley-street, Nottingham, Thomas Geraty, M.R.C.S., L.R.C.P., in his 74th year.

POPE.—On Jan. 31st, at Bournemouth, William Wippell Pope, C.M.G., Lieut.-Colonel late R.A.M.C., aged 68.

STEPHENS.—On Jan. 29th, in London, Augustus Edward Richard Stephens, Lieut.-Colonel (retd.), I.M.S.

WEBB.—On Jan. 29th, at Balitore Cottage, Welwyn Garden City, Helen Webb, M.B. Lond.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## SELECTION OF COD-LIVER OILS FOR MEDICINAL USE.

### BY E. POULSSON,

PROFESSOR OF PHARMACOLOGY, UNIVERSITY OF OSLO.

IN THE LANCET of Sept. 26th, 1925, Prof. J. C. Drummond compares Newfoundland and Norwegian cod-liver oils. He considers that oil from the former country usually has a high content of vitamins, and *recommends it to the attention of* British medical men. We must therein admit that Prof. Drummond is right. The present writer has, in the course of the past four or five years, examined a large number of Norwegian and also some Newfoundland oils, and has received the impression that they are equal as regards growth-promoting activity. A comparison was also made of their antirachitic effects. A large number of rats were placed upon a rickets-producing diet. One group of six animals served as a check. The other groups were given daily doses of from 2 to 8 mg. of Newfoundland or Norwegian cod-liver oil. The control animals exhibited typical symptoms of acute rickets (soft epiphyses, rosy, abnormally high content of water, abnormally low content of lime in the bones), whilst the animals which simultaneously with a rickets-producing diet were given doses of oil were not affected. In order to be on the safe side we give here the average figures from one series of experiments.

A further factor of practical importance is the variation with regard to the content of vitamins. In order to ascertain this we may either determine the lowest growth-producing (or antirachitic) dose. According to Drummond's and Zilva's investigations this lies for the majority of Newfoundland cod-liver oils between 1·3 and 1·6 mg. daily.[1] We can also demonstrate the variations by administring all the oils that are to be investigated in equal doses and then compare the increase in growth produced. In this manner were compared 12 samples of Newfoundland oil procured by the Norwegian Commercial Information Bureau, with 30 samples of ordinary Norwegian cod-liver oil bought openly at various chemists. Each animal was given a daily dose of 2 mg. Each sample of oil was tried upon a group consisting of four rats, and each test-period lasted for four weeks. The results will appear from the following table:—

*Newfoundland Cod-Liver Oil.*

G. = Growth per week in grammes.

| No. | G. | No. | G. | No. | G. | No. | G. |
|---|---|---|---|---|---|---|---|
| 1 | 3·0 | 4 | 7·3 | 7 | 7·7 | 10 | 3 5 |
| 2 | 4·1 | 5 | 4·5 | 8 | 8·2 | 11 | 2 0 |
| 3 | 7·5 | 6 | 0·5 | 9 | 8 0 | 12 | 11·6 |

Arithmetic mean: 5 6.

*Norwegian Cod-Liver Oil.*

| No. | G. | No. | G. | No. | G. | No. | G. |
|---|---|---|---|---|---|---|---|
| 1 | 6·0 | 9 | 5·0 | 17 | 2·8 | 25 | 6·4 |
| 2 | 6·3 | 10 | 5·0 | 18 | 3·5 | 26 | 4 5 |
| 3 | 4·5 | 11 | 6·8 | 19 | 3·5 | 27 | 8 0 |
| 4 | 5·5 | 12 | 5·5 | 20 | 7·5 | 28 | 6·3 |
| 5 | 4·5 | 13 | 7·3 | 21 | 6·0 | 29 | 12·4 |
| 6 | 3·8 | 14 | 7·0 | 22 | 7 6 | 30 | 4 4 |
| 7 | 4·3 | 15 | 3·8 | 23 | 4·0 | | |
| 8 | 4 0 | 16 | 11·3 | 24 | 6·3 | | |

Arithmetic mean: 5·8.

If we take the average figure for all the experiments, the result is that in the said dose the Norwegian oil caused an increase in growth of 5·8 g. weekly, and the Newfoundland oil an increase of 5·6 g. weekly—i.e., that with regard to growth-producing properties they are exactly equal, because in experiments of this kind the errors are greater than the difference found here. It also appears in a most distinct manner that they exhibit somewhat the same variations.

Mention may finally be made of the taste and smell of the oil, both factors of considerable practical importance. In order to be able to make any definite pronouncement on this point I should need a considerable number of samples of Newfoundland oil. Hitherto my impression has been that Norwegian oil is decidedly to be preferred in these respects. This may possibly be due to the circumstance that our most important fishery—viz., that of Lofoten—takes place in the months of February-April, when the average temperature is −2° to +2° C., and that the subsequent Finmark fishery takes place in April–June when the temperature is only a few degrees above 0, whilst the chief season in Newfoundland is in the summer months with an average temperature in August of +15° C. As autolysis and decomposition commences extremely quickly in the liver, even in the course of a few hours, a low temperature is an advantage, although only as regards taste and smell, since the content of vitamins is scarcely affected thereby.

---

[1] S. S. Zilva and J. C. Drummond: Annual Report of the Department of Marine and Fisheries for the Year 1922, p. 19, St. John's, Newfoundland.

The result is, therefore, that oils from Newfoundland and from Norway are equal as regards content of vitamins and variability, and it is therefore quite natural that Prof. Drummond should direct the attention of his fellow countrymen to a product that originates in the British dominions.

To this recommendation, however, he attaches one or two remarks that are not correct and which strongly challenge contradiction. It is said that Finmark oil, like that of Newfoundland, is rich in vitamins, but that oil from Lofoten, our largest fishing district, is often relatively poor in vitamins, "Generally speaking they (the Finmark oils) are found to be from five to ten times more valuable than the average oils prepared in the Lofoten area although wide variations may occasionally be encountered," the reason apparently being that "when the fishes are practically starving during the spawning period, and at the same time are transferring much fat and vitamin to the reproductive cells, the livers yield an almost white oil of relatively low potency."

To this we may remark in the first place that the Lofoten oils have not the said low content of vitamins, and in the next that by the hypothesis just quoted, Prof. Drummond goes contrary to the results that a short time ago were described by him in conjunction with S. S. Zilva and M. Graham.[1] This will appear from the following :—

### *Lofoten Oils.*

Since 1922—i.e., during the last four years—a large number of Norwegian cod-liver oils have been examined, and it has been found that as a general rule the Lofoten oil has a high content of vitamin. Of course, this oil, like those of Finmark and Newfoundland, is subject to exceptions. Particularly important investigations were made in 1925 with a view to obtaining a general survey of oils from all the various Norwegian fishery districts. For this purpose the Superintendent of Fisheries caused a large number of samples, 489 in all, to be collected. Of these average samples were taken to represent each of the more important zones with due regard to the size of the stocks. Thus, from a stock of 800 barrels the sample is twice as large as that from a stock of 400 barrels, and so on. In addition to the large sample from each zone a number were also taken at random in order to establish the extent of the variations. The large Lofoten sample was taken from 86 different factories with a total stock of 12,173 barrels, and should, therefore, reliably represent the average quality of the oil at the time the samples were taken. This was done during the period March 18th to April 18th—i.e., at the time when the fish were ready to spawn or had already spawned. The results of the investigations were that the average sample turned out to be very potent, for even in daily doses of only 1 mg. it promoted growth.

The increase in growth of all the eight rats that were given this dose will appear from the following table :—

38, 50, 60, 56, *56, 58, 62, 73, 80, 79* .. .. .. + 23
35, 48, 55, 58, *60, 66, 62, 68, 70, 70* .. .. .. + 10
46, 55, 66, 65, *61, 71, 78, 84, 85, 88* .. .. .. + 27
45, 57, 65, 77, *73, 77, 73, 74, 84, 89* .. .. .. + 16
41, 55, 66, 73, *71, 77, 85* (Abscess, killed) .. .. + 14
48, 63, 65, 66, *68, 68, 75, 83, 83* .. .. .. + 15
45, 58, 65, *63, 66, 71, 77, 77* .. .. .. + 14
40, 52, 58, 62, *63, 76, 83, 87, 87* .. .. .. + 24

The figures give the weekly weights of the animals, those italicised belonging to the test-period (1 mg. of oil daily), the others to the preparatory period (diet without vitamin A).

### *Relation of the Vitamin Potency of the Liver Oils to the Sexual Condition of the Cod.*

In the sexually mature cod which is ready to spawn the liver is very large and yellow in colour—i.e., full of oil, but during the spawning season the liver shrinks and assumes a reddish hue—i.e., the oil is depleted. It is probable that the fats in the liver have a double action. The cod has a long distance to travel from the open sea to the spawning grounds along the coast. In this comparatively restricted area there is by no means sufficient food for the huge numbers of fish, so that the spawning season is largely a period of fasting. It may be assumed that the stored up liver oil partly goes to sustain the fish and partly to the sexual organs which in the spawning season—i.e., at the very time when nourishment is scarce—increase greatly in size. It might be thought that both vitamins and fats would thus be used up in the same proportion, or that the vitamins would be principally absorbed by the sexual organs. In the latter instance the oil produced from cod which had spawned would be poor in vitamins and of little medicinal value. It has been shown, however, that such is not the case. After numerous investigations I have found no important or constant difference.

To my surprise I discovered a very valuable confirmation of my results in a paper published by Zilva, Drummond, and Graham in 1924, which states: "This passage of the vitamin to the genitals might either have had no influence on the vitamin concentration of the residual oil of the liver in spite of the diminution of the oil content of the organ, or it might have removed more of the vitamin in proportion to the oil. In the former case the potency of the oil during the various stages of the reproductive cycle would not be affected appreciably, in the latter case the livers would yield oils with a diminished vitamin content during the spawning period." The question is therefore very clear, and the authors are in no doubt as to the answer. Fish from Flamborough and Scarborough were the first to be investigated.

The oil was produced by the authors themselves in the usual way. The result was: "Little variation in the potency of the oils could be recorded. Even the liver oils from spent cod in March fish, which must have spawned just before being caught and which had no time to recuperate, did not deviate in potency from the oils of fish before spawning and several months after spawning and consequently after recuperation. It is, therefore, evident that, as the spawning period approaches, the oil and the vitamin from the liver both pass into the gonads. The relative potency of the residual liver oils is, however, not affected. Further confirmation of this observation that the fluctuation in potency of liver oil is not controlled by the condition of the fish in the reproductive cycle was obtained by examining liver oils from various fish caught in the North Sea and in the vicinity of the British Isles at different times of the year—viz., September, 1921 and 1922, November and December, 1921, January, February, April, May, June, July, August, 1922. During this period no serious fluctuation could be observed in spite of the number of samples (about 40 in all) that were examined." The paper concludes with the following summary: "The sexual condition and age of the cod do not influence the vitamin A potency of the liver oil."

It seems to me that Prof. Drummond's statements in THE LANCET in 1925 scarcely correspond with the results of his own investigations in 1924.

## COLONIAL HEALTH REPORTS.

### *Sierra Leone.*

THE territory comprising the colony and protectorate is about the size of Ireland (27,250 square miles). The colony proper as at present constituted comprises the Sierra Leone Peninsula, Sherbro Island, Turner's Peninsula, and a number of small islands, of which the most important is York Island, adjacent to Sherbro, as it is a port of call for sea-going steamers. Freetown, the capital, is situated on the north-east corner of the peninsula on a fine natural harbour formed by the mouth of the Rokelle or Sierra Leone River. The town enjoys a splendid pipe-borne water-supply, the catchment area being situated in the mountains where there are large reservations of land. This and other equally important sanitary improvements have done much towards dispelling the evil reputation from which the city has long suffered. The population of Freetown at the census of 1921 was 44,142. The population of the protectorate, according to the same census, was 1,456,148, composed of various tribes, of which the Mendes and Temnes are the most numerous. The number of European residents during 1924 in the colony and protectorate was 108 officials, 480 military, and 420 non-officials (including white Americans). There was a marked reduction in the incidence of dysentery in Freetown, only 43 cases being reported as against 138 in 1923. Tuberculosis appears to be increasing. Two cases of small-pox were reported in Freetown and there were ten cases in the protectorate. Chicken-pox was fairly frequent both in the colony and in the protectorate; there were no cases of diphtheria, influenza, or cerebro-spinal meningitis. The sanitary department purchased and destroyed 12,708 rats, paying for them at the rate of 1*d*. each. The climate of Sierra Leone is tropical with a heavy rainfall and high atmospheric humidity during the greater part of the year. The shade temperature rarely falls below 70° F. On the other hand it rarely rises above 90° even in the dry season, and there is always a sufficient daily range of temperature to render the mornings and evenings relatively cool. It is not always damp; speaking generally, there are four months of very dry weather, when little or no rain falls, and four months of varying conditions with a moderate rainfall for a tropical country. The single rainy season lasts roughly from May to the end of October, the heaviest rainfalls occurring in July, August, and September. Records of the past 10 years show a marked decrease in the rainfall, and this is said to be common to the whole of West Africa and the neighbouring islands. As to the conditions of living in Sierra Leone, it is remarked that there are facilities for playing cricket, football, tennis, and golf. As the country is hilly, cycling is laborious and horses do not thrive, but for some distance out from the town the roads are good enough for motor-cars and motor-cycles to be used. Local meat is by no means so good as English meat, but when properly cooked is quite nutritious. Excellent fresh fish can be bought, and, apart from potatoes and onions, which are imported, fresh vegetables and fresh fruit can be obtained at reasonable prices throughout the year. A cold storage plant, from which fresh meat and fish, game, &c., can be procured, has been started by one of the European firms in Freetown.

#### *Jamaica.*

Mr. Charles W. Doorly, acting Colonial Secretary, is the author of a report on the affairs of the colony for the year 1924, from which it appears that the estimated population is 904,405. The number of marriages during the period under review was 3118. The births registered were 33,132, being at the rate of 36·8 per 1000, as against 38·2 in 1923. The number of deaths registered was 10,692, the death-rate being 21·7 per 1000, as compared with 22·7 in 1923. During 1924, 35·5 per cent. of the total deaths were those of children under 2 years of age, and of these 27·3 per cent. were those of children under 1 year of age. The principal causes of death per 100 of total deaths amongst the inhabitants of Kingston, the capital, were: Diarrhœa and enteritis, 10·3; atrophy, icterus, and scleroma of the newborn, 11·6; phthisis, 10·7; enteric fever, 5·8; pneumonia, 5 8; heart disease, 6·7; chronic Bright's disease, 4·1; cerebral hæmorrhage, apoplexy, 3·1. During the month of July an Internation Conference on Health Problems in Tropical Countries was held at Kingston under the auspices of the medical department of the United Fruit Company. The Conference was under the presidency of Dr. W. F. Deeks, the general manager of the company's medical department, and was attended by many prominent men of the medical profession from all parts of the world, including Sir Leonard Rogers, Sir Thomas Oliver, Sir Arbuthnot Lane, Dr. A. Castellani, and Dr. F. G. Banting, the discoverer of insulin, and interesting papers were read at the meetings. Increased interest was taken during the year in public health generally throughout the colony. Full-time medical officers of health were appointed for two parishes. The International Health Board (Rockefeller Foundation) pursued their campaign of hookworm eradication. Alastrim continued to exist in the island, but the incidence of the disease decreased during the year to such an extent that the number of cases reported in the last quarter was the smallest since the outbreak started. The advent of rains in the latter part of the year caused local epidemics of malaria. The mean island rainfall of the four divisions of Jamaica for the year 1924 was 79 28 inches, or about 4 per cent above the 50-year average of 76·46 inches. The rainfall for Kingston was 39·19 inches, and the average 33·59 inches. At Kingston the mean temperature for the 12 months was 79·1° F. Hail fell at Kempshot on July 14th during a thunderstorm; also at Santa Cruz on July 30th, accompanied by rain and high wind. A few very slight shocks of earthquake were felt at several places in the island in the months of March, June, July, August, September, October, and November.

### SHANTUNG CHRISTIAN UNIVERSITY, TSINAN.

*To the Editor of* The Lancet.

Sir,—The University Hospital of the Shantung Christian University, Tsinan, North China, is in need of a radiologist, and the board of governors would be very glad indeed to receive an offer of service from a young specialist in this department of medicine, who would be prepared to go out upon a missionary footing. An excellent equipment has been got together, provided largely by the Wesleyan Methodist Missionary Society, one of the coöperating bodies in the University, and that Society is prepared to support the desired worker.

Particulars respecting terms of service will gladly be given by either of the undersigned, and to those looking out for a medical missionary career, who may have had special training in radiology, this opening should present features of attractive interest. We may add that the University is carried on by 15 British and American societies, and is one of the biggest coöperative educational efforts to be found upon the mission field.

We are, Sir, yours faithfully,
R. Fletcher Moorshead,
Hon. Sec., Shantung Christian University.
F. Percy Wigfield,
Medical Secretary, Wesleyan Methodist Missionary Society.
J. Stanley Ellis,
Ex-Radiologist of the University.
Furnival street, London, E.C., Jan. 30th, 1926.

### CLEAN BREAD.

*To the Editor of* The Lancet.

Sir,—One gets tired of hearing so much about clean meat and clean milk—both of them unattainable. The meat, however, is always cooked and so, very frequently, is the milk; it should be always. There is a much more crying evil in the dirty delivery of bread. I have often seen a bicycle fall over and the bread scattered in the gutter. The boy picks it up and polishes it on his dirty sleeve. I have seen worse things in which a dog plays an important part while the boy plays marbles. Men who ought to know better wipe their horse's nose, or feed him with sugar, or mess about with their motor engine and then deliver bread with their filthy hands. The bakers refuse to supply in paper bags because of the cost, not of paper, but of labour. Do please start a crusade against this evil. I fear the local bakers might refuse to supply me with bread if I signed my name and so, in place of it I subscribe this—

Jan. 23rd, 1926. Panis.

*** We have repeatedly advocated the clean handling of bread. As long ago as 1913 M. Herriot, then Mayor of Lyons, issued a decree that loaves delivered other than in a closed vehicle must be completely wrapped in an impermeable covering.—Ed. L.

### THE NORTH-WESTERN NATURALIST.

Medical men have always been active in promoting natural history studies, and their medical implications appeal to those who feel that it may be useful as well as agreeable to hunt for mosquitoes or snails and know all about them. Some of our readers therefore will probably be interested to know that an attempt is being made to start a new natural history journal, the *North-Western Naturalist*, to replace the *Lancashire and Cheshire Naturalist* which unfortunately came to an end last year. Mr. A. A. Dallman (17, Mount-road, Higher Tranmere, Birkenhead), who is known to many medical botanists, will be glad to hear from anyone interested, and especially from those who are prepared to subscribe to the new paper or help to support it through its infancy by some guarantee.

### THE ABDOMINAL MUSCLES.

Mr. F. A. Hornibrook has already published a book on the Culture of the Abdomen, in which he described his system of exercises for the abdominal muscles, and he has now gone further in a second book (Physical Fitness in Middle Life, Cassell, 6s.) by taking up some of the conditions in which these exercises are indicated. It is the middle-aged man who particularly comes in for attention, and it is his overloaded colon, "the White Man's Burden," which gets most of the blame for the physical unfitness so common among this class, especially in our cities. Intestinal toxæmia has attracted many lay disciples. Mr. Hornibrook is guarded in his enthusiasm, and although the idea of practising the contraction of the abdominal muscles while walking to work sounds disconcerting, the general teaching does not lack common sense. The plea for a more rational posture while defæcating is worthy of support. The postscript on the value of wholemeal bread is not convincing, nor is it in keeping with the non-controversial nature of the rest of the book.

### VINOLIA MEDICATED SOAPS.

We have received from the Vinolia Company, Limited, Lever House, Blackfriars, London, E.C., specimens of their medicated soaps which they commend by reason of the fact that they are made from carefully selected ingredients and are the outcome of experience in a large research laboratory, while chemical tests are made at each stage of manufacture. Baby Soap, in which a special base is employed, and to which petrolatum is added before milling, produces an even, soft, and soothing lather, while the Carbolic Health Soap and the Coal Tar Soap, the latter of which contains cresylic compounds with lanolin, are pleasant to use. The Medicated Cream Soap, with which is incorporated boric acid, calamine, zinc oxide, and lanolin, will be found useful in suitable cases, as will also the Sulphur Skin Soap with its colloidal sulphur content. Samples of these soaps will be sent for trial by medical men who apply for them to the manufacturers. We are informed that the works of the Vinolia Company are always open for inspection by members of the medical profession.

At the annual meeting of the Keswick Cottage Hospital it was stated that there were only about 20 subscribers out of a population of about 5000.

Dr. Cyril Hartley Durrant, chief medical officer, has been appointed a member of the Executive Council of the Presidency of Saint Christopher and Nevis for a further period.

# Hunterian Lecture

ON

# PSEUDO-HERMAPHRODITISM AND HYPOSPADIAS.

## THEIR SURGICAL TREATMENT.

*Delivered before the Royal College of Surgeons of England on Feb 1st, 1926,*

By ARTHUR EDMUNDS, C B , M S Lond ,
F R.C S Eng ,
SURGEON TO KING'S COLLEGE HOSPITAL.

*(With Illustrative Plate.)*

The current teaching concerning the operation for hypospadias is well expressed in an article by H. A. Fowler in Cabot's "Modern Urology" published in 1924. In this article the author states :—

> "It is quite apparent, from the numerous procedures which have been suggested, that no entirely satisfactory operation for the cure of peno-scrotal and perineal hypospadias has been devised. This condition still remains one of the most difficult to treat successfully"

The list of names of the authors, who have published operations for the treatment of this condition, is a very long one ; and one is almost driven to think that there can be few surgeons who have not devised an operation. But, in reading the accounts of these procedures, one cannot feel that the authors are writing with any degree of conviction, and photographic records of the results of operation are conspicuously rare. It is difficult to reconcile many of the procedures recommended with the conditions which actually exist, and it is hard to see how anything but a cicatricial mass could result from many of them

An operation, for example, in which the anterior urethra is reconstructed by a stab wound through the vascular fibrous structures of the penis, lined with a transplanted saphenous vein, does not satisfy the demands nor agree with the known principles of surgery; and even should the graft become vascularised, it is still more difficult to understand how the endothelial lining of a blood-vessel can become converted into a mucous membrane.

The use of a section of the ureter is more reasonable ; but this is extremely difficult to obtain, and it must be in only very exceptional circumstances that an operation entailing the removal of a piece of healthy ureter would coincide with an opportunity for transplantation. It has been suggested that the surviving organs from a recent corpse might be used, but, apart from any theoretical considerations as to the use of tissues from another individual, there are obvious difficulties and objections to this. These suggestions, however, are very instructive as showing the despair with which many surgeons view the treatment of hypospadias.

In Keen's "Surgery" the author says, "Occasionally brilliant results are obtained," but I hope to show that not only can an occasional result be obtained, but that these can be obtained in practically every case. The only operation that appeals to me as being on sound lines is that of Bucknall; but this is open to the grave objection that he used flaps of the scrotum with the liability of transplanting hairs into the interior of the urethra. Bucknall quotes three successful cases which he followed up for a few years. Most of the writers in text-books advocate the operation of Beck in which, after the organ has been straightened, a flap of skin is transplanted to the under surface of the penis, fashioned into a tube, and then brought to the tip of the penis through a tunnel made by transfixing the glans. In Mayo's operation a similar principle is adopted, but the tube is fashioned on the dorsum and brought through a stab wound down towards the bladder. It is possible that in some cases these grafted tubes may have survived, but the operation must be fraught with uncertainty, and one cannot help feeling that, even if it were successful, the result would be an organ tied down by a fibro-cicatricial band through its midst.

Josserand has suggested making an artificial tunnel by transfixion lined with a skin graft wound round a rod—an epithelial inlay in fact. These operations have been devised for the milder degrees of the deformity and are obviously unsuitable for the more extreme cases, and, I should think, are impracticable for any case where the opening of the urethra is seated more than a very short distance behind the glans. In Binnie's "Treatise of Operative Surgery" the author advocates Beck's operation when the urethral opening is not too far from the glans, and states that for extreme cases "nothing can be done." The recent development of the tubed flap will, of course, make it possible to transplant as much tissue as may be required on to the penis, but I doubt whether any modification of this method will succeed in producing as natural and satisfactory an organ as the simple flap operation which I describe, although I have no doubt that by its use a tubular organ of any size and length can be readily constructed. The deformity is not extremely rare Five cases occurred in ten years at Queen Charlotte's Hospital out of 18,334 births, and it is fairly obvious that there is room for a satisfactory operation, unless one adopts the point of view that, inasmuch as these patients do not suffer from incontinence, there is no need to do anything

I venture to think that there is no deformity for which treatment is more urgently called. For example, a lady of my acquaintance had a little son born with this deformity Her brother, who was a medical man, regarded it as a family calamity, and a medical friend expressed the opinion "that it would be a good thing if the child died." The parents were extremely anxious that his deformity should not be known. He was not allowed to go to school or to go to any parties or festivities, where the need to urinate and the posture he was compelled to adopt would reveal his condition. This may have been an extreme view to take, but it requires little imagination and knowledge of the average small boy to realise that a schoolboy with hypospadias would be seriously handicapped, and would be liable to unkind comments from his schoolmates. The case I have just mentioned has been operated on with complete success; the child now mixes ordinarily with other children and is preparing for a public school. Beyond this, which one might term a social reason for the operation, there are others. The stream cannot be projected forward, the child, unless carefully supervised, is apt to get wet and the perineum to get sore and eczematous. The child himself realises that he is different from the rest of the community and is liable to various forms of perversion. Marriage is, of course, impossible, and in every way the child's happiness is seriously handicapped

### *Varieties of Hypospadias.*

From the point of view of treatment these cases fall into four groups. In all the prepuce is cleft on the under side and redundant on the upper aspect.

1 The glans alone is cleft. *Usually there is a deep groove on the under surface of the glans, the edges of which lie in close apposition one to another, so that the urethral opening consists of a couple of lips, which are not situated at the tip of the organ, but pass down for a short distance on to its under side. The lower wall of the urethra is usually thinned out at its termination.*

This condition calls for no treatment at all unless the meatus should be constricted. As a matter of fact it is generally abnormally patent. One patient who consulted me about the abnormal appearance of his penis suffered no inconvenience at all, married [illegible] had several children.

2. *The opening of the urethra is situated [illegible] behind the glans on the body of the penis. [illegible] groove in the glans is shallow and [illegible]*

opening is constricted. When the urethra opens far forward there is usually no incurvation of the penis, when it opens near the scrotum there may be a certain amount of curvature. In fact, the nearer the opening of the urethra is to the perineum the greater is the liability to curvature of the penis.

3. The urethra opens at the root of the scrotum and the penis is generally markedly curved. The anterior part of the urethra is generally represented by a shallow groove, which stands out as a taut band when an attempt is made to straighten the penis. At the bottom of this groove the follicles of Littré are seen. The opening of the urethra is bounded below by a thin crescent of skin and is often definitely constricted (see Fig. 1). This should be compared with Fig. 2, which shows the condition of the same patient at the age of 19.

4. There is a complete cleft of the scrotum and the urethra opens in the perineum.

Cases of this last group are often mistaken for females, and in infancy the resemblance is more marked than in older children. The redundant prepuce is continued down on either side resembling the labia minora. A rudimentary vagina may open between the urethra and the anus, and there are, in fact, few, if any, imaginable deformities which have not been described. It is important to distinguish between a male with a cleft scrotum and a female with a hypertrophied clitoris. In many cases the diagnosis is simple, but in others this may be difficult or impossible in the absence of a microscopical examination of the essential sex glands. Cases of doubtful sex should be carefully examined, preferably under an anæsthetic, and if at the end any doubt remains, the old rule—namely, to bring the child up as a male—is, in my opinion, wise.

Undoubted cases have been reported in which ovarian and testicular tissue have been present in the same individual, but it is extremely doubtful whether any individual has ever been bi-sexually potent. There are many old and curious stories, but I doubt whether these would stand scientific criticism. Of course, there are many cases in which the deformity has led to sexual irregularities, but these cases seem to me to afford only one more reason, if one were needed, of the necessity for endeavouring to establish the sex of a child in a doubtful case, and if possible to restore the external parts to as close a resemblance to the normal as possible. The vast majority of cases are, however, psychologically normal, and when abnormality occurs it is quite possible that it is secondary to the deformity.

### RE-REGISTRATION OF CASES OF SEX ERROR.

In any case in which an error has been made about the sex of a child the parents or guardians should not neglect to re-register the birth of the child. A name can be legally changed, or at least added to, at confirmation, it being uncertain whether the original Christian name is cancelled or not.

I am indebted to the Registrar-General for the following statement as to the procedure to be followed in re-registering a child :—

> "In such cases application for the re-registration of the birth should be made to the Registrar-General accompanied by the particulars of the case by the medical practitioner who has examined the child. If this is satisfactory the Registrar would be instructed to re-register the birth on the information of one of the parents or other informant qualified under the Birth and Death Registration Act, 1874. Should there be no qualified informant available, then the original entry would be corrected on the authority of a statutory declaration, made by two persons cognisant of the facts, one of whom would be the medical practitioner."

### THE OPERATION.

The essential characteristics of all these types of deformity are the same, they only differ in degree, and the operation which I describe is suitable for all of them. I first published this operation in THE LANCET (1913, i., 447), but at that time I had only operated upon a few cases and was unable to speak definitely as to the results. I have now operated upon over 20 cases and have been able to see many of these after the lapse of a number of years. I have operated upon all degrees of severity and wish to take this opportunity of presenting my results to the profession.

The operation of constructing the ureter is carried out on the lines devised by Duplay. This operation is perfectly sound in principle, but is, as a rule, impracticable for the simple reason that there is not enough tissue to construct the ureter and clothe the penis in skin. It is to prepare the way for a final Duplay's operation that the preliminary stages to be described are undertaken, and their object is to convert the redundant preputial hood into two flaps along the sides of the penis, including its glandular portion, which can be utilised to line the new urethra and to cover it with skin. This is carried out in three stages, with intervals of three months between. I have found that the best age to operate is about 4—that is, when the parts are sufficiently large to handle and before there is any special sensibility in the organ. Also, as this operation promotes growth, it is essential that it should be performed well before puberty.

*Descriptions of Figures 1 to 10 on Illustrative Plate.*

FIG. 1.—Infant showing the urethra opening at the root of the penis, the curved penis, and the hooded prepuce.

FIG. 2.—The same patient at the age of 10. Six years after the operation had been completed and the wound completely healed a small fistula appeared. This gives him no trouble.

FIG. 3.—Passing the steadying sutures (stage 1).

FIG. 4.—Making the buttonhole.

FIG. 5.—The urethra has been dissected up, the buttonhole cut across, and the incisions into the halves of the buttonhole marked out (stage 2).

FIG. 6.—Method of making incisions into the halves of the buttonhole.

FIG. 7.—Opening up the incision shown in Fig. 5.

FIG. 8.—Suturing the flaps over the raw surface.

FIG. 9.—Condition at the end of stage 2.

FIG. 10.—The incision for the final stage (stage 3).

### *The First Stage of the Operation.*

The first stage is to make a buttonhole in the preputial hood. The simplest way of doing this is to pass a couple of stitches from the mucous or glandular aspect of the prepuce through to the upper or dorsal side. These are placed about 1 cm. apart and 1 mm. from the corona. (Fig. 3.) Holding these sutures taut on either side so as to steady the part, the whole thickness of the prepuce is then transfixed with a scalpel between the two stitches, making an incision extending to within 1 mm. of these and keeping about 1 mm. away from the corona. (Fig. 4.) The end of one stitch is then pulled through the slit and tied to its other end, thus closing the incision at one end by suturing the skin to the mucous membrane. The same procedure is carried out at the other extremity of the wound and a few points of suture are added in between. The slit in the prepuce is thus sewn round like the buttonhole in a coat. It is immaterial how the incision is made in the prepuce, but the tissues are so loose that it is rather difficult to make a neat buttonhole, and the method which I have just described will, I think, be found the best way of doing this.

As a result of this proceeding the prepuce is partially dissected away from the corona, and its main blood-supply—from the dorsum—being cut off, a collateral circulation is induced from the sides which increases its viability in the subsequent stages of the operation. Should the opening of the urethra be at all constricted it should be slit backwards at this stage and a suture passed, uniting the skin and mucous membrane at the scrotal end of the incision.

Three months is allowed to elapse before the next stage of the operation is undertaken, to allow the wound to heal soundly and to allow for the absorption of the scar tissue.

### *The Second Stage.*

So far no attempts have been made to straighten the penis, but this must now be considered. An incision is made along either side of the urethral groove, the two incisions being joined in front in the substance of the glans. The malformed and contracted urethral channel with its rudimentary corpus spongiosum is now dissected up towards the scrotum (Fig. 5), and it will be found that the whole of the urethral groove, originally about three-quarters of an inch in length, shrinks up into an insignificant little knob of tissue. Even in those cases where there has been no curve of the penis it will be found that the urethra shrinks up to much the same extent, and at the close of this stage it is not possible to say whether the penis was originally curved or not.

This stage of the operation must be done very thoroughly so that the organ is completely straightened, and any bands of fibrous tissue which hinder this should be freely divided or removed. As a rule the dissection of the urethra meets the case entirely, but a few transverse incisions on the under surface of the raw area from which this urethra has been lifted may be necessary. This part of the operation is made much easier by passing a guide stitch through the glans to hold everything taut and steady. I have omitted this from most of my drawings for the sake of simplicity, but in actual operating it is nearly always necessary. It will be noticed that the raw area from which the urethral groove has been dissected up is not only longer but considerably broader than one would have expected. Only in exceptional cases is it advisable to remove any tissue in dissecting up the urethral groove. In one case this seemed wise, and a section showed that there was actually a certain amount of erectile tissue in the fragment of tissue taken away.

*Descriptions of Figures 17 to 24 on Illustrative Plate.*

FIG 17.—Diagram of the final result.

FIG 18.—Result of operation soon after its completion, showing the large amount of redundant tissue, which is often present at first.

FIG 19.—*The same patient as in Fig 18 at the age of 18*, the redundant tissue has all disappeared.

FIG. 20.—Pseudo hermaphrodite-sex error, before operation.

FIG 21.—External genitalia of same patient. A catheter has been passed into the urethra and the prepuce held up

FIG 22.—The same patient after operation.

FIG 23.—Result in a child in whom the urethra opened half way down the penis. The meatus is terminal and the penis rather large for the child's age

FIG 24.—The result in a patient age 24.

The preputial half of the buttonhole is next cut across in the long axis of the penis. The two cut surfaces spring apart and in this way two lateral projections are produced which stick out on either side of the glans. The incision which was made to dissect up the urethra is now carried around the corona from the point which would have corresponded to the attachment of the frenum in normal cases to the centre of the coronal attachment of the lateral projections, leaving about 1 mm. of skin attached to the corona. From the termination of these incisions two others are carried out, one on each side, into the lateral flaps dividing the skin on the upper surface only. This may be easily accomplished by transfixing the flap with a sharp-pointed knife as shown in Fig 6. By a certain amount of dissection and a certain amount of stretching of the lax subcutaneous tissue the whole of this incision can now be opened up and in this way an irregular flap is produced on either side of the penis, which will be brought down to cover the raw surface from which the urethral groove has been dissected up. (Fig. 7.)

It is, perhaps, a little difficult to understand the method of formation of this flap, and indeed it would be impossible to construct it were it not that the tissue in this situation is extremely lax and can be stretched without division in almost any direction. One is reminded of the way in which a cook stones a raisin. The little shrivelled-up dried fruit has one side split open, and after the stones have been removed, easily becomes pulled into a couple of discs about the size of the grape before it was dried. One is doing somewhat the same sort of thing with these tissues. When the lateral flaps are dissected up they can be spread out to form a very considerable extent of skin

The position, therefore, at this stage is that we have a large raw area on the under surface of the penis, and at the other side a wide irregular flap with which to cover this in. The covering in process is commenced at the opening of the urethra. (Fig 8 ) The first stitch, passing from side to side, picks up the tip of the shrivelled remains of the urethral groove on its way. The succeeding stitches are passed in such a way that the flaps are held down towards the urethral opening. The stitch is passed, not only through the flaps, but picks up a small piece of tissue from the mid-line of the raw surface from which the urethra has been dissected up, so as to anchor the flaps firmly in this position. The sliding of the flaps downwards is obtained by placing the stitch-holes more widely apart in the skin flaps than in the bottom of the urethral groove This is continued until the whole of the raw area up to the tip of the glans has been covered in.

In this way the whole of this raw area on the under surface is epithelialised and the breadth of the organ increased very materially. A few stitches are inserted along the line of the corona and this will generally be found to entail a folding of the flap, leaving two raw edges which are then sewn together. (Fig. 9 )

As the result of the two stages of the operation which have now been performed, the penis is straight and very considerably broadened. This increase in breadth is due to the two flaps of skin which, originally derived from the prepuce, have now been transplanted on either side of the middle-line. It is now possible to perform Duplay's operation satisfactorily. One point should be remarked. The penis at this stage grows considerably, owing probably to its having been released from the flexed position.

### *Third Stage.*

After a lapse of three months the final stage of the operation can be undertaken. A rubber catheter of as large a size as will conveniently pass into the urethra is inserted for 2 or 3 inches. A stitch is then passed in the mid-line, through the tissues of the glans, and tied with a reef knot so as to make a loose loop. The ends of the stitch are then tied tightly round the catheter and cut short. By pulling on the catheter the organ is stretched out and the instrument made to lie along the course of what is to be ultimately the new urethra. Duplay's operation is then carried out with one or two minor modifications. Starting at the scrotal end an incision is made on either side of the catheter through the tissues, making two flaps of skin wide enough to meet easily over the instrument. (Fig. 10 ) These are joined posteriorly around the urethra, keeping about an eighth of an inch away from the opening It is as well not to continue the incision very far forward at first, but to prolong it towards the glans as the sutures are inserted.

It is also a good plan to make one of the incisions a little further away from the catheter than the other, so that the line of sutures does not fall strictly in the mid line and does not correspond exactly to the line of sutures in the skin. It is highly important for this line of sutures to use very fine needles and very fine catgut. There is no great tension on the stitch, and if holes are made by coarse sutures they very readily become fistulous tracts. 000000 catgut, and the finest curved intestinal needle that will carry it, should be used.

The first—that is to say, the most posterior—stitch is inserted as follows. The needle is passed through the flap (which should not be dissected up more than is absolutely necessary) from the surface, which is towards the catheter, to the raw side. (Fig. 11.) That portion of the tissue destined to line the urethra which lies posteriorly to the urethra is detached with a scalpel, and a stitch passed through this flap picking up a small piece of the subepithelial connective tissue but not penetrating the mucous membrane. The stitch is then completed by being passed from the raw to the epithelial surface on the other side. When the two ends of the suture are tied together it will be found that the epithelium is turned in both posteriorly and on either side, and that the knot of the suture lies in the urethral channel which is being constructed.

The succeeding stitches, which should be about one-eighth of an inch apart, are inserted in the same way—i.e., (*a*) epithelial to raw surface, (*b*) across the wound to the other side, (*c*) then raw surface to epithelium, and tied so that the knots are inside. As the sutures are inserted the lateral incisions are prolonged forwards bit by bit and sutured together. In this way the lining of the new urethra is constructed until the glans is reached. Then the incision should branch off shortly for about a quarter of an inch at right angles to the middle line. The object of this is to prolong the new urethra a little beyond the edge of the glans so as to allow for subsequent shrinking. (Fig. 12.)

FIG. 11.

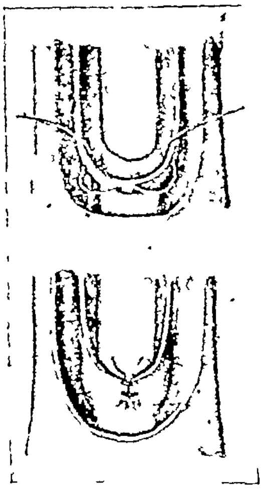

FIG. 12.

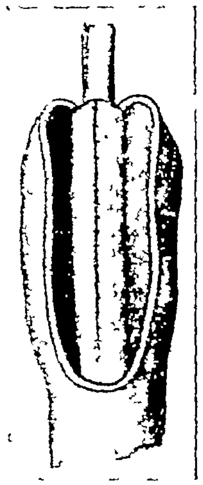

FIG. 11.—Lower end of the incision shown in Fig. 10. Catheter in the urethra. The method of passing the sutures is shown.
FIG. 12.—The urethral tube is completed.

FIG. 13.

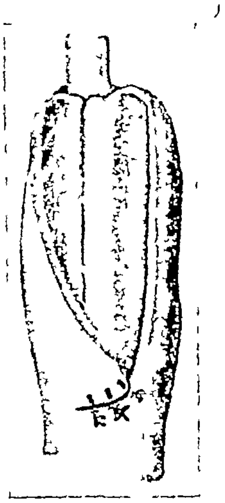

FIG. 14.

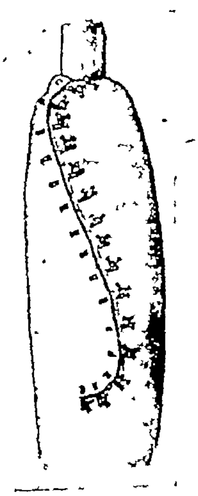

FIGS. 13 and 14.—The closure of the skin. The method of suture described in the text.

The skin is now sutured. If owing to the unequal size of the flaps, the suture line in the newly formed urethra lies a little to the left, the line of suture in the skin will lie a little to the right. The skin incision to be sutured will be found to be, not a long V, but rather a long U, and the first part of the incision should be closed and sutured so that the suture line for the first two or three stitches passes transversely across the penis—that is to say, one side is sewn to the bottom of the U. (Fig. 13.) If this has been done the line of sutures in the skin will not correspond to the deeper row of sutures, but cross them, usually in a sort of S-shaped line. (Fig. 14.) The suturing is continued until the whole of the cutaneous covering of the urethra has been formed. It is highly important in this, as in the preceding suture, to use the finest sutures possible. The needle that I employ is a No. 16 crewel needle, which is the finest I can buy, and the sutures are of "ophthalmic" silkworm-gut. It may be found necessary to dissect up the skin a little, but it must be remembered that the more this is done the greater risk there is of sloughing of the flaps. As a matter of fact the subcutaneous connective tissue is so lax that practically no dissecting or undercutting is necessary.

The vertical mattress stitch which I advocated several years ago is a great improvement upon the ordinary interrupted stitch. The needle is inserted about a quarter of an inch from the cut edge of the skin, passing from the cutaneous to the raw surface, picking up as much of the subcutaneous tissue as possible, then it is passed into the opposite flap, emerging on its cutaneous surface. The needle is then brought back, picking up the extreme edges of the wound as lightly as possible and the suture tied. In this way the epithelium is accurately approximated and the subcutaneous tissue also brought together, obliterating dead space to a great extent. By this method it is also possible to get a good grip of the tissues without sacrificing accuracy. The catheter is now removed.

The wound is then dressed and the patient returned to bed. As a dressing in these cases I have usually employed boric lint which has been boiled in boric lotion. Strips of this are wrapped round the penis and the whole covered in a square piece of the same material. A piece of mackintosh is laid over the lint and the child is pinned up with an ordinary square. Whenever the child passes water the parts are bathed up and the dressing changed.

After the first two stages the child experiences but slight inconvenience. The parts are slightly sore but the patient makes but few complaints. After the third stage the passage of urine for the first time along the new channel is a little painful and it is sometimes difficult to make the child do it. However, a little persuasion on the part of the nurse has always overcome the difficulty and I have never had to pass a catheter, a proceeding I should be loth to carry out for fear of damaging the suture line.

Many cases heal up straightaway, and in all cases the glandular portion of the urethra has healed by first intention. Since I have employed the vertical mattress stitch, and the exact technique of the suture of the skin which I have here described, my results have improved from the point of view of the healing of the wound. But in several cases I have had small failure of healing, rarely larger than would admit a probe, and these have been closed at subsequent operations. Usually I have succeeded at the first attempt, but I have had to make more than one attempt to close a fistula. I have not met with any case in which I have abandoned a fistula as incapable of being closed.

To close a fistula an incision is made round the opening; the skin retracts leaving a small raw area, in the middle of which the mucous membrane of the new urethra can be seen. If the opening into the mucous membrane is of any size it is easy to pass the sutures in the manner already described so that the knots come to lie inside the urethra. If, however, the opening is small, or when one arrives at the insertion of the last stitch, the following manœuvre is useful. (Fig 16.)

FIG. 15.

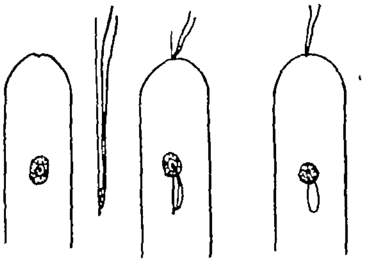

FIG 15.—The closure of a fistula. The method of suture described in the text.

Thread a long needle with fine silkworm-gut and pass it, eye foremost, from the meatus through the fistula, seize the thread, and withdraw the needle. Next, holding the loop out of the way towards the glans (Fig. 16) pass the suture in the manner already described—i e., from mucous membrane to raw surface and thence again to the mucous membrane; tie it. The knot, even though the suture has been passed correctly, will usually not fall back into the urethra, but by threading its ends through the silkworm-gut stitch these can easily be drawn into the urethra. The skin can be closed by turning a small flap of skin over the raw area. It will not be found satisfactory to simply pare and suture the opening.

In none of these cases have I had any clinical sepsis, although it is, of course, almost certain that such wounds do not remain aseptic from the bacteriological point of view. I have never found there was any need to perform either suprapubic cystotomy or perineal drainage of the bladder. These operations are by no means trivial and must inevitably leave the bladder a little less free, and perhaps the seat of a certain amount of infection. I therefore deprecate strongly the advice given by certain surgeons that suprapubic cystotomy should be undertaken in all these operations. It is an operation not devoid of risk and is entirely unnecessary. I have found that it is better not to leave a catheter tied in.

FIG. 16.

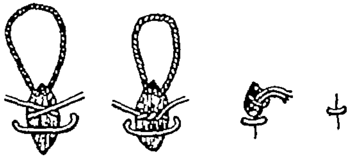

FIG 16.—Enlarged figure of the fistula to show how the knot of the suture is pulled into the urethra.

Beyond the actual fashioning of the flaps it is my belief that success depends upon accuracy of sewing, and that this in its turn depends upon the use of very fine needles and sutures. The ordinary instruments that are used for abdominal section and most major operations are as inapplicable for these cases as they would be for ophthalmic surgery.

## FINAL RESULTS.

In the successful cases, when healing is finished, the meatus lies at the tip of the penis looking slightly upwards (Fig. 17), and the general appearance is that of a child who has been carelessly circumcised, a lot of redundant mucous membrane being left. At one time I thought it might be worth while to remove this at a subsequent operation, but examination of several of my patients a good many years after the operation had been completed proved that the loose tissue is taken up in the process of growth so that in adult life the child looks as if he had been circumcised, not clumsily but neatly. The disappearance of this redundant preputial tissue is very clearly seen by comparing Fig. 18, which shows the result of this operation soon after its completion, with Fig 10, which shows the patient at the age of 18.

The operation which I have just described is appropriate for all degrees of the deformity, even for the perineal type. Many of these cases are mistaken for females, the penis being but little larger than a clitoris. I am strongly of opinion, however, that if these cases were operated upon early in life —for example, at the age of 4 years—the penis, released from its flexed position, would grow considerably.

I have operated upon two cases of mistaken sex successfully. I am indebted to Dr. Gutch, of Ipswich, for the case shown in Fig. 20 This patient passed the first 14 years of his life as a girl, but the descent of the testes, producing a swelling in the groin, revealed the true sex. Fig. 21 shows the appearance of the external genitalia, the prepuce is held up, and a catheter is passed into the opening of the urethra.

I operated in exactly the way which I have described above, making first a buttonhole in the prepuce, and then, after the passage of three months, freeing the urethra and turning inwards the flaps of skin. The presence of labia minora was a help, as these provided additional tissue at the sides. I did one thing, however, which is not necessary in the lesser degrees. At the root of the penis there was a fold of skin corresponding to the skin which so often appears between the labia majora in girls. This I divided transversely, sewing up the wound so made, in the long axis of the penis (like a pyloroplasty). This gave an additional length to the penis. Three months later I completed the operation and constructed the urethra in the usual way. I had some trouble with fistulæ, but these were closed a few weeks later. The final result is shown in Fig. 22. The penis is straight with a terminal meatus. Under the anæsthetic towards the end of his treatment he had a partial erection in which the penis measured 2¼ inches in length. In the flaccid condition it is long enough for him to pass his water in the usual way. Psychologically he is a normal boy.

Fig. 23 shows the result in a child, aged 0, in whom the urethra opened half way down the penis. The organ is quite normal and is, indeed, rather large for his age. Fig 24 shows the result in a case who was operated on rather later than most of the others—namely, when 14 years old. At the time the photograph was taken he was 24 years old. He has a penis which is perfectly normal and was not even noticed by the examining medical officer when he was called up for service in the war.

These cases are not exceptional, but usual with this procedure, and I believe that similar good results could be obtained in practically every case.

# RIGHT ILIAC FOSSA PAIN.

*An Opening Paper read before the Medical Society of London on Feb. 8th, 1926,*

BY H. W. CARSON, F.R.C.S. ENG.,
SURGEON, PRINCE OF WALES'S GENERAL HOSPITAL, LONDON.

Nearly 19 years ago, on April 22nd, 1907, our President opened a discussion in this room on "Surgical Affections of the Right Iliac Fossa which Simulate Appendicitis."[1] His opening remarks and the subsequent discussion were confined practically to acute conditions, and the ground was thoroughly covered except that two or three disorders which we now recognise as liable to diagnostic errors were not referred to. I may mention the abdominal symptoms in chest troubles, the acute pyelitis of pregnancy, and perforated duodenal ulcer. I shall exclude from my remarks any recapitulation of matters already dealt with in that discussion, and confine what I have to say to less acute and to chronic conditions. And I do this the more readily because I believe that acute conditions are much more certainly differentiated, and that even if operation is performed with a faulty diagnosis, the operation is probably essential and the real disorder is discovered and remedied. In chronic cases the outlook is very different, and if diagnosis is not very exact, and if the correct treatment is not instituted, not only is there a failure to cure, but the patient's sufferings may be aggravated.

Although only some 25 years have passed since it was first suggested that chronic inflammation of the appendix might be the cause of continued abdominal discomfort and ill-health, the idea so seized on the imagination of the profession that even to-day it is practically impossible for any of us to avoid thinking of the appendix in every case when a patient comes to consult us for right iliac fossa pain. It was Sir Frederick Treves who was really responsible for putting the idea into our heads. In the Cavendish lecture on Appendicitis, delivered before the West London Medico-Chirurgical Society,[2] he says:—

> "There is a third class of case, abiding pain in the right iliac fossa which may continue for months and may or may not be associated with acknowledged attacks of appendicitis. . . . . These patients are never well. They are the subjects of unending digestive disturbances, of colics, of constipation, and of occasional severe pains. There is often tenderness in the right iliac fossa with a sense of weight and dragging. . . . ."

He goes on:—

> "Removal of the appendix is also to be recommended in chronic appendicitis in those examples in which there are no actual attacks but in which there is abiding discomfort in the right iliac fossa with exacerbations of uneasiness."

It is true he qualified this by saying that "the removal of the appendix is not a panacea for all ills, nor even for all those manifold pains that seize upon the lower segment of the abdomen," but I hope I shall be able to show you that his third class of case is not appendicitis at all, and that treatment by removing the appendix will fail in a high proportion of cases.

### *Muscle Strain as a Causative Factor.*

One of the common causes of right iliac fossa pain is muscle strain, and it is seen in two classes of patient, the young school-girl and the middle-aged athletic man who is giving up his sports and beginning to put on weight. The school-girl strains her oblique muscles owing to a vigorous pursuit of net-ball or lacrosse (both games entirely unsuited to young girls, as they demand considerable exertion with the arms held above the head), the man's pain is due to a commencing inguinal hernia. The girl's pain may easily be diagnosed as appendicitis, as there is often tenderness on palpation. The removal of the appendix in such a case might effect a cure, as it would prevent her playing those games for the rest of the season, but it is rather a drastic method of securing rest for tired muscles.

### *Causative Factors in the Urinary Tract.*

A frequent cause of right iliac fossa pain is some trouble in the urinary tract. A stone in the ureter is, perhaps, the most likely to be overlooked. I am constantly reminded of the possibility by the fact that I have upon my desk at home a silver inkstand suitably inscribed, which was presented to me years ago by a grateful patient after I had removed his appendix for what I thought good and sufficient reasons. He went for a sea-voyage to convalesce, and passed a very small ureteric stone which he sent to me with a cheery letter. It is said that a ureteric stone should always be recognised, because the pain is unilateral, there is often frequency of micturition, the urine may be abnormal, and the stone is discoverable by the X rays. But all the same mistakes occur, and I can show you the X ray of a large kidney stone which gave symptoms leading to the removal of the appendix. It is sometimes very difficult to differentiate by the X rays between ureteric stone and tuberculous mesenteric glands without passing a ureteric bougie, not always a simple task in a child. R. F. O'Neill[3] stated that 25 per cent. of the patients in the Massachusetts General Hospital with ureteral calculi had already had operation on the appendix or other abdominal organ before a correct diagnosis was made. Perhaps we shall hear what the proportion is in this country.

### *Tuberculous Mesenteric Glands.*

Another cause of right iliac fossa pain which may lead to errors in diagnosis is tuberculous glands in the mesentery. I read a paper before the Medical Society on this subject in 1918[4] and tried to lay down a definite symptomatology which, I believe, has been now generally accepted. Since that date I have seen many more cases, and I do not think that further experience has led me to modify in any way the views I expressed at that time.

### *Tumours of the Colon.*

As I have something to say about Treves's third class, I will merely refer shortly to tumours of the colon and their effect in causing right iliac fossa pain. There will, of course, be those cases of a tumour of the right colon, whether it be tuberculous or cancerous. Ileo-cæcal tuberculosis has been admirably dealt with before the Medical Society by Prof. Hartmann in December, 1906,[5] and so complete was his study of the subject that this presentation, though made 19 years ago, is still accepted as the last word on this subject. Both this disorder and cancer of the right colon give rise, in addition to right iliac fossa pain, to a tumour which is in close relation with the anterior abdominal wall and is therefore easily detected; but cancer in the left colon often gives rise to right iliac fossa pain owing to back pressure and distension of the cæcum when the growth itself cannot be felt. Pain in the right iliac fossa with a distended cæcum in a constipated patient over 50 should always make one suspect a stricture in the left colon.

### *Right Iliac Fossa Pain of Obscure Ætiology.*

I will not refer to certain other causes of right iliac fossa pain, such as colitis, diseases of the spine, locomotor ataxy, and tumours of the spinal cord. Let me discuss these obscure and difficult but very numerous cases which may be included under Treves's third class. It is not too much to say that cases of this condition can be found in every medical and surgical out-patient clinic on any day, and they represent an enormous amount of suffering and disability and their cure is still a problem. The sufferers are generally women between the ages of 20 and 40. They are of spare build and have a characteristic carriage due to certain skeletal defects.

[4] Med. Soc. Lond. Trans., xli., 220.

[5] Ibid. xxx., 334.

The head is carried forward, there is slight dorsal kyphosis, the ribs are close together and form an over-acute angle with the rib cartilages, resulting in a flat, narrow chest with a reduced lower outlet. The lumbar concavity is abolished, and the sacrum articulates with the spine almost in a direct line instead of at an angle of 30°. They complain of constant dragging pain in the right iliac fossa, increasing as the day goes on and relieved by recumbency. They have constipation, flatulence, a poor appetite, loss of energy, and symptoms of nervous instability. They complain of joint pains, of neuralgia, of headaches, and nausea. Long ago Moynihan ungallantly divided women structurally into tigers and cows. These are the tigers, and very poor tigers they are. The abdominal wall is poorly developed and many points of tenderness are found in the abdomen, the right iliac fossa is especially sensitive, and often the cæcum is too easily palpable and the kidneys are frankly prolapsed. X ray examination after a barium meal shows ptosis of the stomach and large bowel with delay in emptying. Many of these cases when first seen have already had the appendix removed without relief.

Now what is the cause of right iliac fossa pain in these cases? Obviously it has to do with posture, for it is relieved when the patient lies down. There are two structures in the area which are more mobile than they should be, the kidney and the right colon. Which is it? A good many years ago a mobile kidney was looked upon as an object for attack, but one rarely hears now of nephropexy, an operation that at one time was frequently done. Why has it been abandoned? I think the answer must be that it was realised that the kidney was only one among many displaced organs, and that fixation of this one organ did not bring relief. Is it, then, the right colon? If we examine the right colon in these cases we will find one of two conditions (probably stages in the same condition), either a thin veil of highly vascularised membrane stretching from the parietal peritoneum across the right side of the mesocolon on to the intestine, or a tougher membrane situated rather higher up between the cæcum and the hepatic flexure which may constrict the colon and even bind the ascending colon and the first part of the transverse colon firmly together. The cæcum itself is free. Is it possible that the thin membrane in the first case is sensitive when dragged on by the mobile colon in the erect posture, or that the thicker membrane will, in the second case, so constrict the lumen of the ascending colon when the patient is erect that the cæcum becomes distended and that pain results from spasm of the cæcal musculature in the effort to empty itself? And what of the appendix? Does it show signs of back pressure? Is it distended? Not at all. The appendix is commonly rather small and atrophic and free from adhesions. The cæcum itself is changed. It is thin, bluish in colour, and its walls show microscopical changes. But would these alterations cause pain? There is often a triangular-shaped membrane in these cases on the right side of the mesentery of the ileum just proximal to the ileo-cæcal junction, which may be sufficiently developed to constrict or hamper the movements of the lower ileum. Is this drag on the ileum the cause of the pain? The only answer to these questions is that operations to release these bands and to fix the ascending colon have not met with the success they should have had if they were the sole cause of the trouble.

### *Differential Diagnosis of Chronic Appendicitis.*

But least of all has success attended the removal of the appendix. As long ago as 1919 Connell[6] gave an account of 87 cases who had had the appendix removed for pain in the right iliac fossa without relief; 73 of these cases were women; general ptosis was present in 80; 60 relapsed within 12 months, and of 27 who were subjected to a second operation only 9 showed any improvement. In 1921 Dr. H. W. Bettmann,[7] of Cincinnati, in a paper on Diagnostic Errors leading to Uncalled-for Appendectomy, drew so lurid a picture of the after-results of the operation that THE LANCET had a leading article on it.[8] His conclusions were that the majority of those failures were due to faulty diagnosis, resulting from want of care in examination, and that there was too great a tendency to consider that a case should be operated upon if medical treatment did not effect a cure. While he agrees that the great majority of these removed appendices showed microscopical evidence of disease, from the patient's point of view a clinical cure is more important than the removal of a diseased organ. I think that we will all agree that there is such an entity as a relapsing appendix where you get a history of one or more severe attacks with minor repetitions divided up by intervals of complete health, but is there such a condition as latent appendicitis, and how can it be recognised? I believe it is going too far to say that appendicitis should never be diagnosed unless there has been an acute attack, but we must dismiss from our minds the idea that chronic appendicitis can be diagnosed by right iliac fossa pain alone.

The true symptoms of chronic appendicitis are those of the so-called appendix dyspepsia. The pain is felt in the epigastrium or umbilical region, it is excited by taking food—and particularly some kinds of food—and it is never relieved by recumbency. Nausea is a very common symptom, indeed it is more common in appendix dyspepsia than in any other chronic indigestion. There is often an associated pain in the right iliac fossa, but this is never the only symptom. Nutrition is not impaired nor is there loss of appetite, nor, as a rule, constipation. This picture is in strong contrast to the other type where there is constipation, loss of appetite and energy, deficient nutrition, certain signs of nervous instability, and constant dragging pain in the right iliac fossa relieved by rest. One must not, of course, be carried too far in a desire to explain these dyspepsias as due to appendicitis, yet it is a common thing for every surgeon to be called upon to operate on gastric and particularly duodenal ulcer, and sometimes for gall-stones, in patients who have had their appendix removed without relief. One source of error is that some surgeons remove the appendix through a minimal incision so that there is no chance of examining other organs. I am sure that if there is any reasonable doubt about the diagnosis it is better to open the abdomen in the epigastrium so that the stomach, duodenum, and gall-bladder can be thoroughly examined. It is quite easy to remove the appendix through this incision.

### *X Rays in Diagnosis.*

Now one word about the value of an X ray examination after a barium meal. As a means of diagnosing appendicitis I believe it has little value. I do not think the radiologists themselves are agreed as to whether visualisation of the appendix shows that its peristalsis is so altered that it cannot eject the barium and therefore the appendix is diseased, or whether failure to visualise the appendix shows that the lumen is so obstructed that barium cannot enter and therefore the appendix is diseased. I am sure that tenderness on pressure on the visualised appendix is open to misinterpretation as it overlooks the effect of pressure by a heavily leaded glove on the eleventh nerve. And with regard to ptosis, we must remember that Dr. Ryle has proved most definitely that all ptosis is not pathological. But with these reservations we must admit that X ray examination is of the greatest assistance in the diagnosis of the causes of right iliac fossa pain and is, indeed, invaluable.

I will conclude by saying that in my opinion pain confined to the right iliac fossa should not even be considered as due to appendicitis, especially in the absence of a previous severe attack, until the most painstaking investigation has disproved other possibilities.

# CŒLIAC DISEASE: ITS DEFINITION AND DIAGNOSIS.

BY REGINALD MILLER, M.D., F.R.C.P. LOND.,
PHYSICIAN, PADDINGTON GREEN CHILDREN'S HOSPITAL; SENIOR PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL, PADDINGTON.

To give an entirely satisfactory definition of cœliac disease will not be possible until we know the actual cause of its essential feature, the mal-absorption of fat; but this is not to say that the definitions in use could not be improved. To my mind they err both in what they put in and in what they leave out. They are apt, for instance, to stress *diarrhœa alba* as the diagnostic sign of the disease. Such degree of emphasis is too great, for this symptom may be absent, as in the non-diarrhœic type I have described,[12] and in the classical (diarrhœic) type it only recurs from time to time. In this way there tends to arise the misconception that cœliac disease is one which shows periods of activity and periods of quiescence, whereas in reality the disease remains stationary for many years and the severity of its symptoms depends upon the amount of fat allowed in the dietary. This misconception is further encouraged by the use of the word "relapse" in definitions of this disease. It is no more accurate to speak of relapses here than in a case of diabetes; in either case it is a faulty diet which causes the renewal of symptoms without any necessary change in the disease itself.

Thus far I think I shall carry with me those who have carefully watched cœliac cases, especially if they have controlled their observations by repeated fæcal analyses. But I am anxious to go a step further and to gain acceptance for a definition of the disease which shall aim at excluding certain conditions to some extent simulating it. My point is that the term cœliac disease should be restricted to those cases which show, as the primary cause of all their symptoms, the typical mal-absorption of fat. The purposes of the present paper are, first, to propose such a definition for the disease, and secondly, to mention what other conditions may simulate it and how they may be distinguished from it clinically. I have previously discussed this second matter from the pathological standpoint.[10]

*History.*—It may be helpful to glance back at the history of the disease[11] for a moment when it will be easily understood how some of the confusion as to what is and what is not cœliac disease has arisen. Described originally by Gee[7] in 1888, it was renamed "acholia" by Cheadle[3] in 1903. Both these authors regarded it as a digestive fault rather than as an organic disease, and this view has been maintained, for the most part, by English writers since. In Scotland Bramwell[2] published a series of papers from 1902–15 on some cases of what he called "pancreatic infantilism." His cases were ultimately accepted in England as instances of cœliac disease. Again in 1908 cœliac disease was rediscovered; this time by Herter[8] in America. He regarded his cases as due to a chronic enteritis and named the condition "intestinal infantilism." Not unnaturally it took some time for English physicians to realise that both Bramwell's and Herter's cases were the same as those originally described by Gee, and longer still for this fact to reach America and the text-books. Of recent years American writers have paid us the compliment of adopting the English title, but in the meantime cases of chronic enteritis and of pancreatic disease had been described by various authors and included under the title of "cœliac disease." It is largely in the hope of clearing away these misconceptions that the present paper is written.

*Definition.*—I suggest the following definition: Cœliac disease is a digestive disorder arising in infants and young children who show no evidence of chronic intestinal or other organic abdominal disease; it is characterised by a persistent mal-absorption of dietetic fat which causes large stools containing an excess of split fat, enlargement of the abdomen, lack of growth, and other symptoms.

*Differential Diagnosis.*—The characteristics of cœliac disease which are of most value in diagnosis are as follows: (1) the abdomen is enlarged but shows no signs of organic disease; the buttocks are often peculiarly small; (2) except in severe cases in very young children, the abdominal wall is not conspicuously wasted; (3) with the same exception general wasting is not so severe as is the lack of growth—the weight-for-age is much below normal, the weight-for-height is nearer the normal; (4) the excess of fat in the stools shows that fat wastage is out of all proportion to that of other foods, and it persists when the rest of digestion is normal; (5) on a strictly low-fat diet the amount of fat in the stools remains comparatively high, usually well over 15 per cent. of the dried fæces; (6) the fæcal fat is invariably well split, the neutral fat being usually much below 25 per cent. of the fæcal fat. The last three points display the essential features of cœliac disease.

## I. *Diarrhœic (Classical) Type.*

This is the well-known variety of cœliac disease in which the patient passes large, pale, unformed, and offensive motions containing a great excess of fat (40–80 per cent. of the dried fæces), chiefly in the form of fatty acid crystals. The presence of this fat is liable to set up from time to time signs of intestinal irritation such as mucus in the stools. Careful watching of this type of cœliac disease will soon convince one's mind that these signs are transient, and definitely secondary to the failure in fat absorption.

The diagnosis of this type of cœliac disease may be discussed under various headings.

1. *Rickets.*—The catarrhal diarrhœa of rickety children is usually easily distinguished from the fatty diarrhœa of cœliac disease. In it the fat-loss is neither so excessive nor so persistent. Small children with cœliac disease may show the slighter signs of bony rickets, and at about the age of 7 "delayed" rickets may develop. There is also the well-known association between tetany and other spasmophilic signs in some cases of cœliac disease. But taking the condition as a whole cœliac children escape the grosser forms of rickets in a way which is on theoretical grounds remarkable.

2. *Tuberculosis.*—Abdominal tuberculosis may produce fatty diarrhœa in two ways: (*a*) by inflammation and ulceration of the intestine, and (*b*) by lacteal obstruction due to the presence of tuberculous glands. Both of these will be discussed later.

3. *Chronic Enteritis* (*Enteritic Infantilism*).—That cœliac disease is not due to a chronic enteritis I have argued elsewhere.[14] The difference between the two conditions is quite clear. In cœliac disease there is first a failure in fat absorption, as a result of which may arise a secondary and transient intestinal catarrh. In chronic enteritis there is a failure in the digestion of all sorts of foods, and the intestinal hurry and disease of the intestinal wall may be sufficiently severe to cause an excess of fat in the stools. The most obvious clinical proof of the truth of this is the different lines of treatment in the two conditions; the fat-free diet in the one, and the low, easily digested diet in the other.

Thus the recognition of chronic enteritis proceeds along such lines as these: The wasting of the patient is more severe than the lack of growth. The abdominal wall is usually thinned, and evidence of disease within may be felt, such as enlarged spleen or glands, or thickened intestine. The stools tend to show the presence of mucus and perhaps blood; the digestion of all foodstuffs is impaired, that of the fat with, and not out of proportion to, the rest. As the enteritis subsides so fat digestion improves and does not persistently remain defective as in cœliac disease. Finally, on a low-fat diet the percentage of fat in the stools drops to a lower figure than in the true cœliac case. It must, however, be noted that in some of the cases of persistent enteritis a secondary pancreatitis may develop, as in instances reported by

Poynton[20] and Still.[22] Presumably a pancreatic steatorrhœa might arise from this cause.

Some examples of severe and persistent enteritis will show a distinct degree of stunting of the growth. As Herter has already used the term "intestinal infantilism" for cases which were in reality examples of cœliac disease, I suggest that, if a title is needed for the group I am here discussing, the term "enteritic infantilism" would be accurate and clear beyond dispute.

The following types of chronic enteritis may give rise to difficulty in diagnosis:—

(*a*) Tuberculous enteritis. This can usually be distinguished from cœliac disease with fair ease by the evidence of enteritis in the stool combined with the presence of other signs of abdominal tuberculosis.

(*b*) Chronic enteritis of the dysenteric type. This group may show a clinical picture resembling cœliac disease rather closely; yet the essential characteristics of persistent enteritis are present and enable the distinction to be made between the two separate conditions. The following instance gives the salient features of this type:—

F. R., girl, aged 9. A long history with indefinite onset of diarrhœa with watery motions of varying colour, wasting, and failure to grow. In height she was 3½ in., and in weight 13 lb. below the average for her age. She was in hospital for three months, treated by colon lavage and bismuth and opium. Her abdomen was large; the spleen enlarged under observation. The stools contained mucus, pus, and blood; no true dysentery organisms could be found. At one time the motion appeared fatty, suggesting cœliac disease, and on analysis showed 30 per cent. of fat; but a later analysis showed only 5·8 per cent. Urinary diastase was equal to 10. She had many relapses with blood and pus in the stools, and was ultimately discharged in a quiet phase, having gained no weight. She died at home four months later.

Both Poynton[20] and Still[22] have published fatal cases seeming to me to belong to this type, which is evidently a much more fatal disease than is cœliac disease. In both these cases post-mortem examination revealed not only chronic enteritis but chronic pancreatitis secondary to it.

(*c*) Chronic enteritis due to *Lamblia intestinalis*. This infection has hardly met with the recognition it deserves as a cause of chronic diarrhœa in children. It may produce a slight deficiency in growth. The abdomen is often prominent but the general nutrition usually remains fair. The stools show, in addition to the lamblia cysts, much undigested food and mucus, without traces of blood. The amount of fat in the fæces may be above normal, but does not rise to the figures found in the diarrhœic type of cœliac disease. In a series of my cases of lamblia infection the percentages of fat in the dried stools were 25·6, 23·8, 24·0, 17·2, 21·8, 21·6, 10·6.

In these cases, then, a history of persistent diarrhœa with occasional pale stools and a tendency to diminished growth may very well suggest a diagnosis of cœliac disease. Indeed, I have known specimens of fæces several times sent for examination on this very supposition. Careful examination of the stool will clear up the difficulty, although I should mention that I have known two cases of cœliac disease to show a few lamblia cysts in their stools. I give two illustrative cases of lamblia infection.

K. J., girl, aged 12½. Diarrhœa started in 1917 and has persisted for eight years. Abdomen is large, growth delayed, colour good. Height = 51½ in. (normal about 56–7 in.). Weight in clothes = 61½ lb. Stool report: "Mucus, undigested food, lamblia cysts in very large numbers; does not look like a cœliac stool; fat = 17·2 per cent."

R. H., boy, aged 11. Diarrhœa since age of 3. At 9 he was first seen; he was then having four or more stools a day. He was 3 in. below the average height for his age. His dentition corresponded to that of a child of 7. The stool contained 10·6 per cent. of fat. At 11 years the diarrhœa was beginning to get less; two stools daily. He was growing more rapidly and had reached 58½ in. He appeared very strong and active; weight was 5 st. 12½ lb.

It will be seen that the lack of growth is far less striking in these cases than in the true cœliac group.

(*d*) Enteritis due to irritant poisons. Forsyth[5] has reported a case of severe fatty diarrhœa in an infant of 8 months which was apparently due to the presence of boric acid in the milk. The symptoms ceased as soon as the cause was recognised and pure milk used.

(*e*) Sprue. A recent discussion on sprue and cœliac disease[14] showed clearly that they are different entities. I need not say more here than that sprue is so rare in children as to be unmentioned, if not unknown; while cœliac disease has never been described as originating in an adult.

4. *Pancreatic Steatorrhœa.*—The stool of pancreatic disease is large, pale, offensive, and oily. It contains a great excess of fat, and its diagnostic feature is the distribution of the fæcal fat; a large proportion, over 25 per cent. at least, is in the form of neutral, unchanged fat. This shows itself in the stool, if present in large amount, as separated oil or grease which congeals on cooling ("butterstühle"); if in smaller quantities the neutral fat shows under the microscope as oil droplets. This sort of stool does not occur in cœliac disease; there the fat in the fæces is invariably well split. Pancreatic steatorrhœa is a rare phenomenon in childhood, especially if we look for cases in which pancreatic disease has both been recognised during life and verified after death. Several groups of cases are known.

(*a*) Congenital steatorrhœa. This is perhaps the best recognised entity. The first case was described by Garrod and Hurtley[6] in 1912, the second by the present writer and Perkins.[10] A fæcal analysis in a third case has been reported by Mackenzie Wallis,[24] and another example has been shown at the Section of Diseases in Children of the Royal Society of Medicine.[19] So far as I know these are all the cases as yet recognised. The condition starts from birth and is almost certainly due to an inborn absence of pancreatic lipase, the other functions of the pancreas remaining unaffected. It is noticeable that these cases do not seem to suffer from stunting of growth. This is one of the proofs of what I have urged previously (THE LANCET, 1923, ii., 1090), that lack of growth in cœliac disease is not due to a mere fat deprivation, but is a toxic effect.

(*b*) Acquired pancreatic disease in children may occur, as mentioned above, as a sequel to chronic enteritis. It has also been attributed to inherited syphilis.

(*c*) Pancreatic infantilism. It has already been stated that Bramwell's cases, described under this term, must be regarded as examples of cœliac disease. It should be emphasised that the author himself referred to other cases which he could not distinguish clinically from his pancreatic cases except that they failed to improve under treatment by pancreatic preparations; these he thought were probably of the type then recently described by Herter under the name of "intestinal infantilism." Nevertheless, there do appear to be cases of true pancreatic infantilism. Perhaps the clearest clinical evidence is shown in the case reported by Moorhead,[17] in which steatorrhœa of the pancreatic type started at the age of 18. Mumford[18] published one of apparently the same type, which, however, ultimately attained to a normal height. Rentoul's case[21] is perhaps less satisfactorily proved. In none of these was there any verification after death. Bramwell,[1] on the other hand, reported a post-mortem on a case in which no clinical history was obtainable. The subject was a woman aged 20 showing very definite infantilism. Autopsy revealed the presence of mitral endocarditis and chronic pancreatitis. It is only proper to add that no ovaries could be discovered.

(*d*) A peculiar case has recently been published by Clarke and Hadfield.[4] In it steatorrhœa of the pancreatic type appeared to date from birth and there was stunting of growth. An autopsy at the age of 4 years showed that the gland substance of the pancreas was atrophied to about one-twentieth of the normal although the islets remained intact. If this were truly a congenital case it is, so far as I know, unique.

5. *Lacteal Obstruction.*—Fatty diarrhœa has long been known to be produced by lacteal obstruction, although such a condition is a rare one. The one cause of such obstruction which is definitely known is the presence of tuberculous mesenteric glands. It is important to notice that such obstruction would exactly reproduce the fatty stools of cœliac disease. Just as in biliary obstruction (unlike pancreatic disease), so in lacteal obstruction, the fat in the stools would be mainly split fat. The diagnosis here would, therefore, rest mainly upon the recognition of tuberculous glands in the abdomen; if they were to be felt I should not myself at the present time regard the case as one of cœliac disease.

J. Ryle [22, 23] has recently put forward the suggestion that the symptoms of cœliac disease are due to lacteal obstruction. It is, however, abundantly clear that tuberculous glands, which are practically the only recognised cause of such obstruction, are not the cause of it in this disorder. For this statement I adduce the evidence from a series of over 40 cases of cœliac disease which have passed through my hands. Not one has shown evidence of overt tuberculosis in the abdomen or elsewhere, and this in spite of lasting invalidism in many instances; nor do autopsies, few though they are, discover such glandular lesions. It is not a rare thing to discover clinical evidence of tuberculous mesenteric glands, and it is impossible to imagine that it is always those which cannot be felt which should produce lacteal obstruction. Further, of the three cases brought forward by Ryle, two showed important differences from the ordinary type of cœliac disease.

If, then, we can set aside tuberculous adenitis as the cause of lacteal obstruction we are in great difficulties in suggesting any other condition, especially any infective condition, of the glands to account for the obstruction. It would have to be one which could produce, in some instances at all events, an apparently sudden obstruction of the lacteals which could last for many years and ultimately allow of great improvement in the absorption of fat; and, further, to do all this and yet never spread, even in tiny invalid children, to any organ in which it could be recognised clinically. Nevertheless, we must not forget that lacteal obstruction would give rise to the typical cœliac stool just as accurately as would the defective action of bile salts.

### II. *The Non-Diarrhœic Type.*

In this type [12] the symptoms are all milder than in the classical type. The enlargement of the abdomen, the lack of growth, the loss of appetite, and other symptoms can all be recognised, although of less severe grade. The chief difference between the two groups lies in the appearance of the stools. In the classical type, when severe symptoms are present, the stools are large, pale, unformed, highly offensive, and containing 40–80 per cent. of fat, chiefly in the form of fatty acids. In the non-diarrhœic type the stools are again larger than normal, but they are coloured, formed, not offensive, and contain 30–50 per cent. of fat, chiefly in the form of soaps. Similar stools are passed in the quiet stages of the diarrhœic cases. [9, 15]

In the diagnosis of this type I have found most difficulty arise in connexion with two groups of cases: (1) temporary over-feeding with fat; (2) chronic enfeebled digestion of all foodstuffs. The diagnosis may be reached with careful watching on the lines already given above, by a consideration of the essential diagnostic points in cœliac disease.

I desire to express my grateful thanks to my colleague, Dr. H. Perkins, pathologist to the Paddington Green Children's Hospital. The large number of fæcal examinations and analyses which he has made for me forms the basis of whatever may be of value in this paper.

JUNIOR PHYSICIAN, KING'S COLLEGE HOSPITAL; FORMERLY RADCLIFFE TRAVELLING FELLOW, OXFORD UNIVERSITY.

Among the rarer diseases of familial incidence is a curious condition of which the features are summed up in the name multiple familial facial telangiectases. A number of families have now been recorded since Wickham Legg described the first in The Lancet of 1874.[1] The marked symptom of the condition is epistaxis, coming from the lesions in the nose or bleeding from similar lesions elsewhere. In 1865 Babington [2] described a condition which he called hereditary epistaxis which was very likely the same condition as Legg recorded nine years later, but he gave no description of any lesions. The following is the account of a family in which a number of its members show telangiectases.

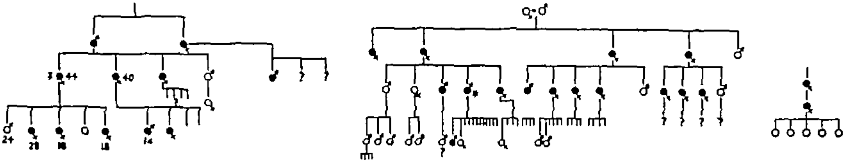
### *Clinical Records: First Family.*

The first member of the family I saw was a woman aged 44, who came to hospital with symptoms due to secondary anæmia. On examining her tongue one could see some eight little telangiectatic spots scattered over the dorsum. They were bright pink in colour, round, and varied from 1 to 3 mm. in diameter. There were several on the inner and upper surface of the lower lip. These were about the same size as those on the tongue or rather larger. One or two of the largest formed little dark purple blebs. Another was inside the left lower eyelid, and there were two under the finger-nails. Several were scattered about on the backs of the hands and wrists. With the exception of those on the lip all were small round pink spots. She said that she had first noticed the spots on her lip about five years ago, for they had been prone to bleed when she was eating. About this time also she had had a good deal of nose-bleeding. This had been sufficiently severe to send her to hospital. Lately she has been free from this, and no nævi are to be seen on the lower part of the septum. Other members of the family are also affected. She states that her father had a cluster of small telangiectatic spots around the nostrils and inside the nose. From these he often had bleeding.

She has four children living. The eldest, a man of 21, has one or two small nævi on the face, but has never had nose-bleeding. Her eldest daughter, aged 20, has small nævi on the lips and tongue like her mother. There is also one in her left eye. These have all appeared quite recently, and she has lately had a good deal of epistaxis. Apart from these she has had some spots on her hands and face for some time. The youngest daughter has several spider nævi scattered over the body; she has never had epistaxis and she says the spots come and go quite quickly. There are none on her face. The third daughter has no nævi.

The patient has two sisters. The elder has a few telangiectatic spots on the bridge of her nose; she has never had nose-bleeding. Of her four children, the eldest, a boy of 14, has two nævi on the nose, and the next, a girl, has a few on the face. The other two are free and none have had nose-bleeding. Her younger sister has had a good deal of trouble with nose-bleeding, which came on when she was about 18. She has had to have her septum cauterised. Her aunt, her father's sister, has small nævi all over her tongue similar to those on the patient. They are also present on her upper lip and round the nostrils and on her hands. Those round the nose have caused much bleeding for which she had to go to hospital. This woman has three children, one of whom, a boy, often has nose-bleeding. Lately this has been worse, and during the last five years small nævi have appeared on *his tongue and lips.*

The family tree shows the symbol dark where the individual has telangiectases. There are 11 members affected. Some are very slight lesions and have hitherto caused no trouble. In fact, one would hardly notice them unless one was on the look-out for them, nor would one attach any importance to them apart from the fact that their owners are members of a family in which they have a definite incidence, and that in some they have caused a great deal of trouble and discomfort.



First family

Second family

Third family.

In each family the asterisk (*) denotes the patient. ? = No information. The sex sign is shown in black in affected persons. Line of descent short when persons under age at which lesions appear

### *Second Family.*

A little time ago I described another family in which a number of members were affected with telangiectases.[3]

Here the original patient was a man of 48, who came to hospital with chronic bronchitis and emphysema and heart failure. He died a few months later. He had many telangiectases scattered all over both cheeks especially on the cheek bones. There were some over the eyes and on the nose and inside the nostrils. The spots consisted of spider nævi and many dilated capillaries joining them up. In places the dilatations appeared to involve small veins as they had the appearance of small dark purple blebs about 2 mm. in diameter. His mouth and the rest of his body were free. He had suffered very often from epistaxis. The cyanosis due to his cardiac condition made the lesions especially marked. The spots and the nose-bleeding first came to notice when he was about 23. He said that his mother and two of her sisters had similar spots on the face, as did also two of his sisters. They were beginning to appear on the face of his eldest son who was 23. All the members of his family who have the spots suffer from nose-bleeding, some of them very severely. As far as I was able to ascertain there are 15 members of his family who have telangiectases and epistaxis. Those affected are marked in black in the family tree.

A curious point about this family is the age at which the spots are first noticed or the nose-bleeding starts. Most of those affected first showed signs in the early 'twenties. They did not appear so early in life as is the case in a good many instances, and, moreover, they did not tend to appear later in life either. If the individuals passed the age at which the lesions usually came without their appearing, they seemed to escape altogether.

### *Third Family.*

The third family which I have come across has only two members affected. A woman of 55 came to hospital first with high blood pressure and arterio-sclerosis. She had a number of irregular spider-like nævi, mostly on the right cheek, but with a few also on the left. These had first appeared when she was 33. The telangiectases were mostly in the form of fine irregular vessels radiating from one central spot. Here and there were larger vessels, round, raised, and dark purple in colour. Since the spots first appeared she had a good deal of nose-bleeding. This had been worse lately, no doubt made worse by her general vascular condition, although it brought relief to her symptoms. She said that her mother had had similar spots on her face only very much more marked. They had come when she was about 45 and were accompanied with severe epistaxis. The patient's five children had all died young and she did not know of anyone else in the family affected. Her mother had been an only child and she was also.

### *Recorded Cases.*

A number of families in which this remarkable disease has occurred are now on record. Steiner[4] analysed most of the cases in 1917, and in 1921 a very full review of the literature was given by Goldstein.[5] He alludes also to a number of cases which have been recorded which gave no family history of the disease. He brought the total up to 31 families, to which another described by FitzHugh[6] in 1923 must be added. The three which form the subject of this paper make 35 in all. Sir William Osler wrote the first comprehensive account of the condition in 1901,[7] and a further article in 1907[8] about which time Parkes Weber] reviewed most of the cases previously published.[9]

### *Ætiology.*

Most of the families belong to the Anglo Saxon race. A few have occurred in the Latin races, one or two in the Teutonic and Scandinavian races, and some of the families have been Jewish. At first the disease was confused with hæmophilia by several writers. It seems likely that the marked secondary anæmia which so often accompanies the condition may have given rise to this idea, for in these circumstances the blood changes would make hæmorrhage more likely to occur and more difficult to stop. In some cases the delay in the coagulation time noted may also be due to this anæmia.

### *Pathology.*

The disease is due to a familial tendency for defects to appear in the small blood-vessels. The pathological changes were studied by Hanes[10] and Osler[8] who found dilated vessels, the walls of which were thin and deficient in muscular and elastic tissue. This condition renders hæmorrhage likely to occur on very slight injury. Such vessels would not retract effectively, and so bleeding would tend to be profuse.

The character of the lesions varies a good deal. One may see irregular dilated venules scattered more or less thickly in a sort of network or mat. Another type is the spider nævus where little vessels radiate from a central dot about the size of a pin's head. Others appear as tiny round pink dots, not more than 2 mm. in diameter as a rule. There are also little purple raised spots which look like little blebs and may be as large as a small split pea. The last variety may bleed very profusely when injured. They are distributed chiefly on the face, especially on the cheeks and nose. They occur very constantly on the septum of the nose, low down in front. They are often found on the mucous membrane of the mouth and tongue and less extensively on the rest of the body; here the hands and under the nails are the commonest places. In one case which came to autopsy a telangiectasis was found in the stomach, and there is evidence to show that they may occur on the brain. Bleeding chiefly occurs from the spots in the nose, but it not infrequently starts from the mouth during eating and sometimes from the face or elsewhere if a spot is damaged.

In the majority of cases there is a history of bleeding from the nose, starting in childhood. This is so in 40 out of 57 cases in which there is a definite account. Other persons show no sign of the disease until middle life. Often in childhood the spots are not at all conspicuous, and they become more prominent as the patient grows older. Epistaxis is then the only symptom. When the lesion appears later in life the spots appear on the face very often about the time that the patient begins to complain of epistaxis. Occasionally the spots are there but no epistaxis occurs.

### *Incidence and Transmission.*

In the 35 families reported, 237 persons have suffered from the disease. In 25 instances the sex is not stated, but of those where the sex is mentioned 104 are males and 108 are females. The disease thus affects males and females equally. The disease appears to be transmitted rather more often by females than males. It has been transmitted by the mother 53 times and by the father 38 times. For the most part the disease appears in each generation. Sometimes it appears to die out in one branch of the family, and occasionally a generation is skipped. This occurs definitely in five instances and there is a probability of it having occurred in two others. The disease is present in the grandparent, lies dormant in the parent, and reappears in the grandchildren. This has happened very probably seven times in 91 recorded transmissions.

### *Treatment.*

The only really effectual method of stopping the bleeding is cauterisation of the bleeding-point. Various drugs have been recommended with a view to increasing the coagulability of the blood, but it seems clear that they can do little when the fault is in the vessels themselves. Later they may be useful when there is marked secondary anæmia, for such a condition would tend to prolong the hæmorrhage when once it had started, thus setting up a vicious circle, as was pointed out by Parkes Weber.

### *Discussion.*

Apart from this disease, with its familial incidence, quite a number of cases are on record which resemble the cases in these families in every way except that there is no family history of the trouble obtainable. There is a possibility that some of these sporadic cases may be really instances of atavism, and that the disease has lain dormant in one of their parents, or even for more than one generation. Although nothing is known about the cause of this familial abnormality, telangiectases certainly do appear in association with a number of conditions. Sir William Osler pointed out their curious relationship to cirrhosis of the liver. They may appear quite suddenly in catarrhal jaundice, and disappear equally rapidly. Nævi are also frequently seen in the scars of X ray burns. They may appear on the face in Graves's disease. It is well known that alcohol tends to promote their appearance in some people, as does also exposure to the weather. The combination of these two factors was no doubt responsible for the complexion of some of the old London 'bus drivers. Here constant dilatation seems to have led to a condition of permanent ectasia. Possibly in the cirrhotic and jaundice cases the local action of a toxin on the vessels leads to degeneration of the walls and the pressure of the blood within them does the rest.

But quite apart from any of these associations there is a tendency for telangiectases to appear in people as they grow past middle age. The lesions in the sporadic cases always show themselves late in life, never in childhood as in the familial cases. The condition may, then, be arrived at perhaps through the action of toxins on the capillaries in the acquired cases or through some familial developmental error. In all the cases under review the lesions have been confined to the capillaries or small venules. There is, however, in some cases a history of the blood spurting from the spot as though a tiny arteriole were involved. One may draw a parallel between these local lesions of the smaller vessels and the extensive lesions which involve all the branches of some large artery, a cirsoid aneurysm. A cavernous nævus seems to be the same condition appearing in a large vein and its branches. All such changes may be found in one individual, as in a case which I reported[11] of a woman who showed a cirsoid enlargement of the arteries of the right arm with great dilatation of the veins of the hand. There was also a large capillary nævus on the left cheek. In the production of some cirsoid aneurysms no doubt a congenital defect in the vessels is the cause. Before the character of the lesion was recognised this disease was called hereditary epistaxis. Cases of hereditary hæmaturia have been recorded by Pearson[12] and Aitken.[13]

Hæmaturia does sometimes result from telangiectatic areas in the bladder and renal pelvis. A boy, aged 8, was admitted into King's College Hospital under Sir Watson Cheyne in 1901, with a two years' history of hæmaturia. There was a large nævus with warty excrescences on it on his thigh which sometimes bled, and on operation a similar nævus was found in his bladder. Is it possible that hereditary hæmaturia may result from telangiectatic lesions in the urinary tract? On the whole it seems unlikely. In none of the recorded families was there any history of bleeding except from the spots on the face. Hæmaturia is never mentioned. Although the lesions do sometimes appear in these families on the internal organs, it is quite the exception.

Reference may be made to an interesting family recorded by Libman and Ottenberg.[14] In this case it was one of hereditary hæmoptysis. In the families with nose-bleeding it is true that hæmoptysis may occur, but there are easily seen spots in the pharynx, or, as occurred in one case, on the epiglottis. In the family where hæmoptysis was the only symptom no lesions from which the blood might have come were seen, even with a bronchoscope. It is possible, of course, that the lesions are in the lung tissue.

The disease is of importance because of the serious inconvenience the epistaxis causes the patients and because of the grave secondary anæmia to which it may give rise. In three instances death has been due directly to the hæmorrhage. The severity of the hæmorrhage late in life is, no doubt, partly due to the general vascular changes and increase in blood pressure which are commonly present.

### *Conclusions.*

1. Three families are described which show multiple facial telangiectases. 2. The disease is due to a congenital vascular abnormality generally appearing in childhood. 3. The hæmorrhage tends to become more severe when the condition is complicated by severe anæmia or vascular disease. 4. The condition appears equally in males or females, but is transmitted rather more often by the females. 5. The disease may be latent in some generations and reappear later.

# CARCINOMA OF THE PROSTATE.

## TECHNIQUE OF OPERATION.

BY A. CLIFFORD MORSON, O.B.E., F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL FOR URINARY DISEASES.

UNTIL Young, of Baltimore, demonstrated that malignant disease of the prostate could be removed by a perineal operation no attempt had been made to extend the experiences gained in cancer surgery in other parts of the body to this region. Young's operation aimed at the removal not only of the gland, but also of the base of the bladder; but he was the first to admit that his after-results were unsatisfactory in two respects—namely, permanent incontinence of urine due to damage of the nerve-supply of the compressor urethræ, and the formation of a recto-vesical fistula.

The principles which underlie the operation I have devised differ in no material respect from Young's, but whereas he gained access to the tumour by the perineal route, in my operation the bladder is opened above the pubes and removal of the diseased tissues carried out under direct observation. The preliminary communication on this subject was made before the Section of Urology of the Royal Society of Medicine in March, 1924. During the succeeding 12 months further experience has enabled me to elaborate my original technique and shorten the time required to complete the operation.

### *Anatomy of the Region.*

A reference to the anatomy of the vesiculæ seminales and prostate is necessary in order to explain the raison d'être of my technique. The vesiculæ seminales may be described as a pair of convoluted organs situated at the base of the bladder between it and the rectum, and converging towards the upper pole of the prostate, to terminate as ejaculatory ducts. By their anterior surfaces they are closely approximated to the base of the bladder, and posteriorly to the rectum, the fascia of Denonvilliers and loose areolar tissue intervening. The upper ends lie against the ureters at the termination of their intravesical portions. The inner border of each vesicle is in relation to the corresponding vas deferens and its ampulla, with which it is united by a band of fascia. The vas deferens winds round the upper pole of the seminal vesicle to pass outwards to the lateral wall of the pelvis. Its relation to the ureter is variable. In the majority of cases it separates the ureter from the vesicle, but occasionally it takes a different course and, becoming hooked round the ureter, the vas lies between it and the bladder wall.

It is not necessary to describe the anatomical relations of the prostate gland, but, in order to appreciate the pathology of malignant disease in this organ attention must be drawn to the fasciæ which make up the prostatic bed, the *loge prostatique* of the French writers. This, for practical purposes, is well described by Denonvilliers, one of the first to study the subject. He describes an aponeurosis running from the anterior surface of the prostate to the symphysis pubis. The apex of the prostate is supported by the deep layer of the triangular ligament. On either side is found the so-called lateral aponeurosis of the prostate, which passes backwards from the rami of the pubis to join the rectum. Between it and the gland is cellular tissue. Separating the seminal vesicles and the prostate from the rectum there is the prostato-peritoneal fascia or fascia of Denonvilliers; this is attached below to the prostate and triangular ligament and united above to that part of the peritoneum which descends between the bladder and the rectum. By its posterior surface it is but loosely attached to the rectum, but by its anterior firmly fixed to the seminal vesicle and the true capsule of the gland. In the living subject I have observed that there is a band of fascia extending from the junction of the seminal vesicle and the prostate to the descending ramus of the pubes. This often contains a blood-vessel and, though hardly a ligament in the correct sense of the term, one may refer to it as such and give it the title of pubo-seminal.

### *Mode of Spread of Prostatic Cancer.*

Having drawn attention to these anatomical details it will be convenient, at this stage, to mention how, from the pathological standpoint, the fascia of Denonvilliers plays an important part in the spread of prostatic cancer. If a careful microscopic examination be made of the seminal vesicles with the terminal part of the vas deferens in a case of advanced carcinoma of the prostate, it will be found that the cancer cells spread out fan-like beneath the bladder from the parent mass. These cells pass along the lymphatic channels buried in the fibrous tissues which envelop the vasa deferentia and the seminal vesicles. In no case have I seen the glandular epithelium of the latter organs infected by cancer. Thus in theory the removal of the seminal vesicles is unnecessary, but in practice it is unavoidable. At the point where the fascia of Denonvilliers becomes attached to the peritoneum forming the most dependent part of the pouch of Douglas, the further progress of the migration of the malignant cells in this direction appears to cease, for the peritoneum acts as a barrier. The cells are, however, diverted towards the ureters which they embrace and stenose.

The pathology of carcinoma of the prostate is of absorbing interest, and in a subsequent communication will be dealt with in detail, but the purpose of this article is to draw attention to the advantage of a radical operation which will prolong life, and if undertaken in the early stages will make the eradication of cancer in the prostate as probable as in other organs.

### *Technique.*

The operation, for purposes of description, can be divided into two stages, the first stage consisting in the separation of the prostate from the surrounding structures, and the second the dissection and removal of all the tissues which form the base of the bladder as far back as the inter-ureteric bar and the anterior wall of the rectum. In both stages it is essential to have plenty of light in the bladder itself and to have the bladder wall well retracted. Headlights throw 80 per cent. of their rays on to the skin of the anterior abdominal wall and, unless very powerful, are unsatisfactory in bladder surgery. This is particularly true of lamps attached to the forehead. The best means of illuminating the bladder is to insert an electric lamp into its cavity. Such a lamp was devised by me a few years ago. This can be attached to the bladder retractor, and has proved to be reliable. Retraction of the bladder walls is readily accomplished by means of a self-retaining retractor of the Thomson-Walker pattern.

A good exposure of the internal meatus and bladder base can only be obtained if the patient is placed in the Trendelenburg position. The operating-table should be tilted to the right angle before the suprapubic incision is made, and not when the bladder has been opened. The circulation of elderly people is slow in responding to alterations of positions. When the bladder has been opened and the retractors inserted an incision is made round the internal meatus and with a blunt dissector the line of cleavage between the growth and fibrous capsule determined. This line of cleavage is quite definite, even in advanced cases, owing to the failure of the malignant cells to penetrate this capsule. Should the mucous membrane of the bladder base be thickened or actual malignant nodules be seen with the naked eye, the incision is carried back to the inter-ureteric bar, and a triangular area mapped out, the apex being at the internal meatus and the base between the two ureteric orifices. The next step consists in separating the prostate from the *loge prostatique*. As soon as partial mobilisation of the gland and its growth has been accomplished, with the aid of Duval's forceps, the mass is delivered into the bladder with its attachments to the base of the bladder and seminal vesicles still intact.

The second stage of the operation consists in the removal of all tissues anterior to the front of the rectum including the mucous membrane of the bladder base, if considered invaded by the disease. By pulling the prostate out of its bed the pubo-seminal ligaments are put on the stretch. These are then clamped and divided, thus permitting the scissors to be inserted between the anterior wall of the rectum and the fascia of Denonvilliers. With great care this fascia and the seminal vesicles are stripped off the loose fatty tissue which intervenes between them and the bowel. It is now advisable to search for the vas deferens, either on the inner side of the seminal vesicle or at its apex. Should the tissues between the seminal vesicles be infiltrated with growth the vas can only be isolated at the point where it comes into relation with the ureter. The variability of this relation, as already described, makes this part of the operation tedious and difficult, for ascending infection will follow a division of the ureter in its intramural portion. When the vas deferens has been isolated it should be ligated as near the brim of the pelvis as possible, and at the same time the glands in this region dissected out. Division of the vas allows the prostate, seminal vesicles, and surrounding tissues to be still further separated from the rectum. When this has been accomplished on either side all that remains in order to remove the whole mass is to divide the fascia of Denonvilliers at its attachment to that part of the peritoneum which forms the bottom of the pouch of Douglas. Button-holing the peritoneum need cause no anxiety provided the opening into Douglas's pouch is immediately closed by sutures. On the other hand, it is a serious mistake to button-hole the rectal wall. A recto-vesical fistula results, and though the patient may survive this complication and even live many months, his condition will be pitiable. One case in which this mistake was made survived 18 months. By the perineal route injury to the rectum is often unavoidable, by the suprapubic route it is due to carelessness. The operation is completed by inserting a Marion's tube into the bladder.

With the removal of the malignant growth a large, raw surface is exposed, the base of which is formed by the rectum and the sides by the torn edges of the bladder walls. As healing proceeds this cavity contracts, but after so extensive an operation the base of the bladder and prostate bed are also filled in with scar tissue which narrows the urethral outlet. In every case, therefore, subsequent to the closure of the suprapubic opening, the new internal meatus must be dilated at intervals with gum elastic or metal bougies. The alternative to this procedure is to give the patient a permanent suprapubic fistula. The immediate after-treatment differs in no respect from that usually practised at St. Peter's Hospital for the simple enlarged prostate.

### *Advantages of the Operation.*

The discussion of a surgical operation is incomplete without considering its suitability to the extent of the disease for which it is intended. This is especially true of malignant disease, one of the most difficult problems yet to be solved being the accurate detection of deep-seated metastases. Attention has already been drawn[1] to the difficulty of correctly interpreting the size of a growth of the prostate by palpation through the rectal wall. As a method of investigation to determine whether surgical removal of the malignant mass is feasible it is unreliable.

Palpation of the glands in the groins should be part of the routine examination, and their obvious enlargement, though not contra-indicating the major operation, increases its risk. Dissection of these can be postponed until three to six months have elapsed from the time of the prostatectomy. The cystoscopic appearance of the mucous membrane of the internal meatus and base of bladder is a most valuable guide in determining the extent of the disease. Gross infiltration by cancer cells in the regions indicated produces nodules, congestion, and œdema. If the growth has reached the inter-ureteric bar and is invading the muscle-fibres of the vesical portion of the ureters, ascending infection to the kidneys will occur and cause a failure of renal function. All the reliable methods of estimating the latter must, therefore, be carried out before it is decided whether the case is operable. Lastly, the assistance of the radiologist must be obtained to search for bone metastases. My views during the past 12 months have been somewhat modified with regard to the value of skiagraphy as a means of detecting all deposits in bone. In some cases they were only revealed post mortem.

By such an operation as I have described the danger of death from pyelonephritis, which is the usual terminal stage in unoperated cases, is banished, provided the ureter is not divided; but it must be admitted, as always in malignant disease, that metastases may occur even in the most favourable cases. My record of cases demonstrates, however, that a greatly improved state of health results from this operation.

# ABSCESS AND GANGRENE OF THE LUNG.

## REPORT OF TWO CASES, WITH A SHORT STATISTICAL STUDY.

BY T. PEARSE WILLIAMS, M.D. LOND., M.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS, PADDINGTON GREEN CHILDREN'S HOSPITAL AND WILLESDEN GENERAL HOSPITAL; LATE MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

THE following two cases of abscess of the lung came under my observation recently. The opportunity has been taken to collate some statistics of cases of abscess and gangrene of the lung occurring in a large general hospital over a period of 25 years.

CASE 1.—J. M., a man aged 40, was admitted to the Middlesex Hospital under the care of Dr. A. F. Voelcker in June, 1923. He complained of pain in the right iliac fossa, extending back to the right lumbar region, which had been present for three days. Twenty years previously he had served in Africa, India, and Egypt as a soldier, with no serious illness except an attack of jaundice. He was healthy looking, with a good colour. The tongue was furred; temperature 99·6° F. There was tenderness in the right iliac fossa and right hypochrondrium, but no rigidity. Liver dullness was diminished. Movement of right chest was diminished, and the percussion note impaired over the right lower lobe. Tactile fremitus was lessened, the breath sounds weak, and a few medium bubbling râles were heard. Sputum was scanty and not offensive. Exploratory puncture was performed, and 10 c.cm. of a clear sterile fluid removed. Ten days after admission pleural friction was noted at the right base, the moist sounds were more numerous, and the sputum had increased in quantity and become muco-purulent.

Three weeks after admission signs of cavitation were noted in the posterior axillary line at the level of the seventh rib, and the percussion note over the right upper and middle lobes was now impaired, with deficient air entry. Orthopnœa was present, cyanosis, and clubbing of the fingers. X ray examination showed diminished excursion of the diaphragm on the right side and density in the right costophrenic sinus, above which was a clear area of lung surmounted by a dense rounded opacity, possibly an abscess. *Entamœba histolytica* cysts were found in the stool at this period, and a course of emetine hydrochloride was given.

The patient's condition gradually got worse, wasting, increasing cyanosis, and a more copious and offensive sputum being noted. In the third week of July an exploratory operation was undertaken by Mr. E. L. Pearce-Gould and a large abscess cavity in the lung was drained. The patient died a few hours later. Post mortem a large subdiaphragmatic abscess was found, communicating with a large abscess cavity in the lower lobe of the right lung. A healed duodenal ulcer was found, but no abscess of the liver.

The case is of interest in that the primary focus of infection was never definitely localised. It is possible that the subphrenic abscess arose from the duodenal ulcer, became encysted and eventually infected the lung.

CASE 2.—H. A. P., a man aged 43, of robust physique, was admitted to the Middlesex Hospital in March, 1921, with signs of consolidation at the base of the lower lobe of the right lung. He was treated with an autogenous vaccine of pneumococci. Later in the year he attended the out-patient department for a short period, when signs of pulmonary fibrosis were noted. In May, 1923, he returned to the out-patient department and gave a history of three severe attacks of coughing associated with severe dyspnœa and much thick sputum. He was admitted under the care of Dr. Voelcker in June, 1923. He complained of pain over the left upper chest, dyspnœa, morning cough, and expectoration. He had lost much weight since his previous admission, was pale, neither cyanosed nor dyspnoic, and had a temperature of 101° F. There was diminished movement of the left chest, percussion note was greatly impaired, and vocal fremitus much diminished over the left upper lobe. Air entry was very poor over this area, and coarse and medium râles were present; rhonchi over the remainder of the lungs. The sputum was neither offensive nor excessive; tubercle bacilli were not present. Five days after admission he was suddenly seized with a violent bout of coughing, sat up, became cyanosed, and within five minutes fell back dead.

Post mortem a large abscess cavity was discovered in the left upper lobe filled with a reddish-brown grumous material which was not offensive. No tubercles were seen and there was no evidence of pulmonary tuberculosis. Larger bronchi opened into this cavity, which was lined with a grey-green exudate. The surrounding lung tissue was firm and airless with much fibrous tissue. Here the original lesion was probably a broncho-pneumonia, fibrosis with residual infection occurred, and the abscess gradually developed. It is unusual for such a cavity, apparently with free bronchial communication, to retain its contents so long and for the latter to remain inoffensive.

### *Relative Frequency of the Complication.*

An investigation of the records of the Middlesex Hospital over a period of 25 years was undertaken in order to obtain some figures as to the relative frequency of these highly fatal complications. Fifteen cases of abscess and 16 cases of gangrene were recorded during the years 1898–1922, in an average admission of 1400 cases per annum. The death-rate in this series was 80 per cent. for abscess, and 81·25 per cent. for gangrene. The average age of the patients suffering from abscess was 37 years, and of those suffering from gangrene 41·8 years, or omitting one case in a child of 3 years, it was 44 years. The oldest patient in this latter group was aged 70 and she recovered. The following tables show briefly the primary cause of the disease and the result.

TABLE I.—*Abscess.*

| Primary cause. | No of cases. | No. of deaths. |
|---|---|---|
| Lobar pneumonia . | 1 | 1 |
| Influenza and influenzal pneumonia | 3 | 2 |
| Broncho-pneumonia . . | 3 | 3 |
| Intra abdominal disease . . | 3 | 2 |
| Puerperal sepsis, pyæmia . .. | 1 | 1 |
| Uncertain, pyopneumothorax . | 1 | 1 |
| Typhoid and dysentery, 20 years previously .. .. | 2 | 1 |
| Inhaled foreign body .. | 1 | 1 |

TABLE II.—*Gangrene.*

| Primary cause. | No of cases. | No. of deaths. |
|---|---|---|
| Lobar pneumonia .. .. . | 3 | 2 |
| Influenza and influenzal pneumonia | 2 | 1 |
| Broncho pneumonia .. . .. | 3 | 2 |
| Cardio-renal sclerosis .. .. | 1 | 1 |
| Cirrhosis hepatis .. . . | 1 | 1 |
| Diabetes with granular kidney | 1 | 1 |
| Cardiac dilatation and hypertrophy | 1 | 1 |
| Carcinoma ventriculi . .. .. | 1 | 1 |
| Gastric ulcer .. . .. .. | 1 | 1 |
| Gangrenous pharyngitis .. .. | 1 | 1 |
| Uncertain .. .. . .. | 1 | 1 |

In the series of cases of abscess it will be noted that in eight of them the primary disease was in the lung, and a ninth case was due to the inhalation of a foreign body. Lobar pneumonia only accounted for one of these cases, though abscess and purulent infiltration are always stated as complications. Influenza accounted certainly for three cases and probably for a fourth, all between the years 1899 to 1902. From 1898 to 1909 all cases of pneumonia were classified together and amounted to 1285 for the 12 years. From 1910 to 1922 there were 772 cases of lobar pneumonia and 378 cases of broncho-pneumonia, besides cases arising during the course of other diseases and not separately recorded. Abscess, therefore, as a complication of lung disease only occurred in 0·32 per cent. of cases, and the percentage incidence for lobar pneumonia is no doubt less. Fränkel[1] records, on the other hand, abscess formation in 2 per cent. of pneumonias. The physical signs varied, usually an impaired note with diminished air entry; signs of excavation were less frequent. The sputum in the majority of cases was copious, more than 20 oz. a day in three cases, muco-purulent, and offensive. Hæmoptysis occurred in one case, and pleural friction was noted in one case. Post mortem the lower lobe was involved in six cases, and the upper and middle lobes in three. In the remainder multiple abscesses were present. In one case a large effusion of dark purulent material, 150 oz., was present in the pleural cavity.

In the series of cases of gangrene several cases occurred as terminal infections in chronic disease, and the age-incidence was higher. Clinically the symptoms were more severe, fever being higher and rigors frequently noted. The sputum was always extremely foul and, except for the child of 3 years with gangrenous pharyngitis, contained blood, though the child had a blood-stained discharge from the pharynx. Signs of excavation were present in four of the cases, a pleuritic friction in two. Post mortem the lower lobe was involved in 11 cases and the upper lobe in two. In the remainder numerous areas of gangrene were present.

With regard to the question of surgical interference, all the cases of gangrene were gravely ill, and such treatment was only tried in one case of abscess recorded at length. It must be noted that the majority of these cases occurred prior to 1914, since when the surgery of the chest has made great advances, and methods of radiological localisation have been greatly improved.

In reading through the case reports from which these statistics have been compiled it is evident that the diagnosis of these two lesions was in the majority of cases a difficult one. This difficulty was also apparent in the two cases cited at length; in one of them the lesion present was not diagnosed during life. Though the ætiological factors, speaking generally, are the same, whether abscess formation or the more severe gangrenous change is to occur, appears to depend very largely on the resistance of the patient and the severity, virulence, and type of the infecting organism.

When the final results are examined the death-rates of the two conditions are approximately equal, and cases treated medically are almost invariably fatal. Verneuil[2] in 1900 recorded a death-rate for gangrene of 80 per cent., and Lenhartz[3] in 1905 a death-rate of 70 per cent. Medical treatment, therefore, does not appear to have been any more successful in the last 20 years. P. H. Pierson, writing in Billings-Forchheimer's "Therapeusis of Internal Disease," 1924, also quotes a mortality-rate of 60 per cent to 90 per cent. in cases treated by medical measures.

Surgical treatment certainly offers a greater hope of cure. The induction of a pneumothorax is unsuccessful in many cases on account of the presence of adhesions. Sauerbruch[4] performs an open operation, draining the cavities. He gives figures of his results; the mortality-rate for acute abscess was 15 per cent., for chronic abscess 37 per cent., and for cases of gangrene 51 per cent. Where the disease process is progressing rapidly or a foreign body is present which cannot be removed by the bronchoscope an immediate operation is advisable; in other cases time should be allowed for the abscess to become walled off and pleural adhesions to form.

My thanks are due to Dr. Voelcker for permission to publish the two cases recorded here, which were under his care, and for his criticisms of this paper, and to the other members of the staff of Middlesex Hospital who have allowed me to use the records of their cases for the second portion of this article.

# NOTES OF 100 CONSECUTIVE CASES OF SCOPOLAMINE-MORPHINE NARCOSIS IN CHILDBIRTH.

By E. C. PLUMMER, M.R.C.S. Eng.,
ST. FAITH'S NURSING HOME, EALING, W.

The narcosis, called "T.S." for brevity, was administered by me, and the patients were under my close observation in my nursing home; 61 were primiparæ, 39 multiparæ. Other confinements in the home during the same period but without T.S. afforded means of comparison.

### *Method.*

The injections were hypodermic, usually into the arm, the patients being kept in bed. The room was darkened and absolute quiet observed. Dark glasses were not used, and wool ear-plugs were employed in one case only.

The first dose for primiparæ was morphine gr. ¼ and hyoscine gr. 1/100, given when the patient said the pains were becoming severe. The personal factor of sensitiveness to pain and general nervousness naturally affected the length of the period between the earliest pains and the first injection, but patients were encouraged to bear the slighter pains. Vaginal examinations were not made unless specially indicated, but where they were called for it was found that dilatation rarely exceeded 1 inch without severe pains.

For multiparæ the first dose was morphine gr. ⅙ and hyoscine gr. 1/100, given as soon as labour began and without waiting for severe pains. No injection was given if it appeared that labour would be over in three hours or less; with this exception the cases were not selected in any way. The second dose was usually hyoscine gr. 1/150 an hour after the first; in one case gr. 1/100 was given. Subsequent doses consisted of hyoscine only; in no case was any more morphine given. The frequency and amount of the doses, from gr. 1/150 every hour to gr. 1/450 every two or three hours, were determined by the response to memory tests. Amnesia, not analgesia, was aimed at, and in no case was analgesia obtained.

In nearly all cases a little chloroform was given at the end of the second stage, and unless an ordinary dose of hyoscine had been given recently I found it advisable to give a small dose shortly before the end of the second stage to ensure sleep continuing after the birth; I regard this sleep as a very important factor in attaining complete amnesia. Water was given freely, and in long cases milk or beef essence.

### *Duration.*

For primiparæ, the longest interval between the first dose and delivery was 55 hours, the shortest 1¾ hours, average 13½ hours. For multiparæ, the figures are 15½, 2, and 5¼ hours respectively. It is obvious, therefore, that the duration of labour is not increased, as has been stated. On the contrary, it appears that at times it is shortened by the removal of inhibition and the preservation of strength by sleep.

### *Total Dosage.*

For primiparæ, the greatest amount of hyoscine was gr. 11/120 in 29¼ hours, the least gr. 1/100 in 1¾ hours, average gr. 1/25. For multiparæ, the figures are, gr. 7/150 in 8 hours, gr. 4/450 in 2 hours, and gr. 1/43 respectively. I have not been able to trace any relationship between the temperaments of the patients and the amount of hyoscine required; for example, two successive primiparæ, young, healthy women, each of whose T.S. lasted 9¼ hours, required five injections totalling gr. 1/30, and seven totalling gr. 1/20 respectively.

### *Course.*

The patients slept practically throughout labour; with the more severe pains they might stir uneasily and groan, and possibly complain of the pain, falling asleep again directly the pain passed off. In many cases what was uppermost in their minds was what had occupied them when labour began, such as their domestic and household arrangements. The following is a typical instance of a patient's utterance: "Oh dear I can't stand any more this twilight sleep isn't any use why don't they give me some more I suppose they have run out of it I think I'll have toasted cheese for my supper." The whole was muttered without a pause, the last nine words signalling the end of the pain and that this had been forgotten; the patient then went off to sleep. Four patients became excited, trying to get out of bed, but obviously quite unconscious of their surroundings. A further dose of hyoscine and the inhalation of a little chloroform controlled the excitement and produced sleep. Subsequent doses in these cases were the usual ones—no greater dose than usual was necessary to maintain quiet sleep. Four patients, though not restless or excited, slept very little; they talked irrelevantly and disconnectedly most of the time, and fancied their relatives and friends were with them. The 55-hour case was in this class.

### *Amnesia.*

Of the primiparæ, over 90 per cent. remembered very little after the first injection, and nothing after the second had taken effect, until a varying period after the birth was completed. I have already mentioned the importance of sleep immediately after the confinement. The remaining primiparæ had some vague recollections of various details and incidents, more or less distorted and confused as to time, &c. With the multiparæ, those who had previously had T.S. successfully, were again successes as regards amnesia. With those who had had prior confinements without T.S., or with whom on former occasions the T.S. had not been successful, it was found that, although the case might now be a complete clinical success as regards amnesia, yet the memory of the previous confinements was often transferred to the present one. The patient would say she remembered all the pains, the birth, and everything else, but investigation of her memory for times, number of injections, &c., would show that amnesia was perfect, and that the origin of her impressions was a previous confinement. As a rule, the patients realised this later.

It was quite usual for both primiparæ and multiparæ to say they could hardly realise the baby was theirs, and that they had lost from a few hours to two or more days of time. Many also apologised for having been so noisy and troublesome, when in fact they had been perfectly quiet and placid.

*Inertia* was infrequent; in one case only was it severe, that of the 55-hour primipara. She was over 40 years of age, unhealthy and flabby, with a very septic mouth. She had vague feeble pains for 24 hours before the first injection, the pelvic outlet was narrow, and a difficult forceps extraction under full chloroform anæsthesia was ultimately necessary.

*Third stage* was completed in under 30 minutes except in two cases; in both of these the placenta was nipped partly in the uterus and partly in the vagina.

*Hæmorrhage* was severe in one case only, and was easily controlled by kneading and the injection of pituitary extract. In no other case was any increased tendency to hæmorrhage, as compared with ordinary cases, observed.

*Temperature.*—The usual reactionary rise after delivery was entirely absent in the majority of cases; in the others it rarely exceeded 99° F.

### *Puerperium.*

With the exceptions to be detailed convalescence was very rapid, owing to the absence of shock and exhaustion; it was the rule for mothers to say they felt well enough to get up two or three hours after delivery. This well-being at such an early stage was perhaps the most notable feature from the point of view of the patients' friends. Even the 55-hour case, with full chloroform anæsthesia at the end, felt perfectly well a few hours after. In no case were there any mental symptoms. There was no vomiting with T.S. alone, other than that during the first stage of labour, and this was quite infrequent and slight. Where much chloroform in addition was given the tendency to vomiting was undoubtedly less than with chloroform alone. The exceptions to a normal puerperium were:—

(1) A case of eclampsia; urine found loaded with albumin at the onset of labour; 15 fits in 24 hours after delivery; no further fits, convalescence uninterrupted after. A primipara who had had the usual T.S. (2) A case of slight thrombosis of the veins of the back of the calves of the legs in a thin, ill-nourished woman, beginning on the fourteenth day after delivery. (3) and (4) Two cases of delayed involution, with persistent red lochia, requiring rest in bed beyond the usual 14 days, douches, &c. Both were mothers of several children.

*Lactation* was unaffected.

*Infants* were not affected harmfully; on the whole, they were more placid and contented during the first few days of life than those born without T.S. It seems only rational to consider that the infant, during its birth, shares in the mother's freedom from the consciousness of suffering. Artificial respiration for shock ("white asphyxia") was required in the 55-hour case, and in two other cases after difficult forceps extractions with considerable chloroform. All three babies did well. There was no other case of greater severity than some sluggishness of breathing for a short time—oligopnœa.

The following abnormalities occurred:—

(1) Twins, stillborn and premature: combined weight 5 lb. The mother, a primipara aged 37, had had a severe shock a week previously, and had felt no movements since. No fœtal heart was heard. Duration of T.S. 21 hours, total dose gr. 7/120. Delivery unassisted by forceps. (2) Breech; stillborn. Primipara. Cord four times round neck. Duration 23½ hours; amount gr. 1/30. (3) Breech; stillborn. Primipara. Cord round neck. Duration 37 hours; amount gr. 13/200. (4) First vertex; stillborn. Primipara of very small build; difficult forceps extraction; weight of child 6½ lb. Duration 10½ hours; amount gr. 1/120. (5) Anencephalic monster, stillborn, vertex presentation. Primipara. Duration 10 hours; amount gr. 13/300. (6) First vertex. Primipara aged 40, unhealthy, with pyorrhœa. Slight inertia. No vaginal examination made. Membranes ruptured spontaneously, liquor amnii brown and turbid with foul fæcal odour. Delivery spontaneously after ½ c.cm. pituitary extract during second stage. Birth of head followed by rush of liquor, some of which the child inhaled, dying 80 hours later of pneumonia. The mother made an uninterrupted recovery without rise of temperature.

### *Later History.*

Many of the mothers and children of this series, and others who had previously had T.S. in the home from two to nine years ago, have been seen since leaving the home. The children are healthy and bright and at least up to normal standards both physically and mentally. I have not heard of any instance of mental or moral defect, so often stated to be the result of T.S. Many mothers have remarked how much more quickly they have recovered than their friends who have not had T.S. Very many have volunteered the statement that they would not mind how many children they have, as regards the confinements, if they can have T.S. One mother has had four confinements, and many have had two and three, with T.S. There is no evidence to support the not uncommon idea that T.S. leads to drink or drug-addiction.

### *Conclusions.*

Provided that the dosage is limited to the production of amnesia only, and is adjusted to the individual, there do not appear to be any contra-indications. The constant supervision that is essential makes T.S. unsuitable, save in exceptional circumstances, for administration in the patient's own home. In hospitals it is difficult to ensure quiet. Full chloroform anæsthesia may be given at any time during T.S. for such procedures as version or rotation of an occipito-posterior presentation, the T.S. being continued afterwards if necessary; or for a terminal forceps extraction, perineal repair, &c. Fortunately, no more serious operative procedure has been necessary in this series, but there seems no reason to anticipate that any such would be prejudiced, either as to the operation or the anæsthetic, by the fact that T.S. had been given.

One great advantage of T.S. is that as the mother is conserving her strength by sleeping, instead of getting worn out by repeated pains and the constant dread of more and worse ones, cases can be left much longer to Nature than would otherwise be possible; in uncomplicated cases the use of forceps merely for the mother's sake is avoided, with consequent lessened risk for both mother and child.

I have to thank Dr. H. O. Davies and Dr. R. H. Dixon for permission to include details of patients under their care in the home, my part in such being limited to the administration of the T.S.

# Clinical and Laboratory Notes.

## A CASE OF
## "LAG" GLYCOSURIA.

BY E. M. WATSON, M.D. WEST ONT., M.R.C.P. EDIN.

(*From the Clinical Laboratory, Victoria Hospital, London, Canada.*)

THE sugar-tolerance test has provided a means for distinguishing between true diabetes and other conditions showing the presence of sugar in the urine, unassociated with any defect of carbohydrate metabolism. In this latter category may be placed, among others, cases of renal glycosuria and, perhaps, certain cases described as "lag" glycosuria. Owing to the lack of certain knowledge concerning the last-named condition, a record of the following case may be not without interest.

### *Clinical Record.*

The patient, a man aged 52, was admitted to hospital on August 24th, 1925, with the following complaints: (1) loss of weight, (2) loss of appetite, (3) vomiting, and (4) constipation. Three months previously he began to vomit after food, his appetite failed, and he lost 40 lb. in weight. He has had no pain with the exception of an occasional burning sensation over the epigastrium. He has never vomited blood nor noticed blood in the stools. There has been no excessive thirst, and the volume of urine has not been increased. Radiographic examination showed the stomach to be contracted to a capacity of about two ounces; the barium meal rushed through into the intestine without delay (a gastro-enterostomy had never been performed). Routine examination of the urine revealed an intermittent glycosuria.

### *Laboratory Findings.*

1. *Urine.*—On a full diet glucose appeared in the urine after meals and disappeared on fasting; the amount varied from a trace to 2 per cent. The urine showed an absence of ketone bodies and of protein. The diastatic index was 10.

2. *Glucose-Tolerance Test.*—

| Time. | Blood sugar (per cent.) | Urine (per cent.) | Sugar (amount) |
|---|---|---|---|
| Before glucose .. .. | 0·087 | 0 | 0 |
| After glucose (50 g.)— | | | |
| ½ hour . .. .. | 0·222 | — | — |
| 1 " .. .. . | 0·098 | 0·80 | 238 mg. |
| 1½ hours .. .. .. | 0·070 | — | — |
| 2 " .. .. .. | 0·080 | 0·57 | 102 mg. |

3. *Fractional Gastric Analysis.*—There was no fasting gastric content. Fifteen minutes after a gruel meal a small amount of material resembling saliva was recovered which did not give a reaction for HCl or starch.

4. *Other Findings.*—Blood Wassermann, negative. Non-protein nitrogen, 29·1 mg. per 100 c.cm. of blood. Tests for occult blood in the fæces, negative on three occasions. B.M.R., −12 per cent.

### *Discussion.*

A discussion of the clinical condition of this patient will not be attempted; only one aspect of the case will be considered—namely, the blood-sugar curve and the glycosuria. MacLean[1] has described the "lag" type of blood-sugar curve. Its chief characteristics are a rapid rise to a maximum of 0·22 or 0·23 per cent. in half an hour, followed by an abrupt decline to normal. There is a concurrent glycosuria.

The interpretation of such an effect presents some difficulty. Is there an abnormality of the carbohydrate storage mechanism such that it requires an unusually high blood-sugar concentration to set it in operation? Or is the mechanism merely temporarily overwhelmed by the rapid absorption of a large amount of glucose? Considering the velocity with which the stomach emptied itself in the case recorded above, the latter explanation would seem to apply, in this particular instance at least. That the carbohydrate storage function is efficient, once it becomes active, is demonstrated by the fact that the blood-sugar curve returns to the normal level within the recognised standard limit of time. Bennett and Dodds[2] have shown that solutions of glucose, under normal conditions, are detained and diluted in the stomach.

According to MacLean the "lag" type of blood-sugar curve is of little or no prognostic significance, although he states that some investigators claim that the condition may terminate in a true diabetes. In a case reported recently[3] the patient is said to have had the condition for 30 years without showing any tendency to pass into a true diabetes.

The case described in this note not only serves to emphasise the importance of the glucose-tolerance test in throwing light upon glycosurias of uncertain origin, but also suggests that cognisance should be taken of a possible relationship between the emptying time of the stomach and the distortion of the carbohydrate metabolism in cases of the "lag" type.

Thanks are due to Dr. J. C. Wilson and Dr. G. C. Hale for permission to publish this case.

## NOTE ON AN UNUSUAL CASE OF SUPRACLAVICULAR ADENITIS.

BY FRANK BODMAN, M.B. BRISTOL, M.R.C.S. ENG

THE following case is of interest on account of its unusual character.

W. F., aged 50, reported that two days previously, while hay-making, he had fallen off a wagon on to the shoulder and had since been unable to use the arm. On examination by candle-light a tender swelling over the middle of the clavicle was discovered. There was pain on attempting to move the arm, and drooping of the shoulder on the affected side. The patient was mentally deficient and very deaf. Diagnosis of fractured clavicle was made. Next day it was noticed that the tender swelling was above the clavicle and beside a well-marked deltoid tubercle, the lower border of the clavicle being unbroken. This was confirmed by a skiagram. Further examination discovered a small granulation under the nail of the thumb. The patient complained of no pain there. There was no enlargement of glands in the axilla. The supraclavicular swelling was fomented for 48 hours—no fluctuation could be detected at any time. Glycerine of ichthyol was then applied and the swelling resolved.

Wood Jones[4] states that in fœtal life the cephalic vein empties into the external jugular instead of the subclavian, and presumably its accompanying lymphatics terminate in the supraclavicular glands. Kanavel[5] states that the most external collecting trunk of lymphatics from the hand occasionally passes over the clavicle to empty into the supraclavicular gland.

Bristol.

## FLOATING HEPATIC LOBE.

BY A. J. E. CAVE, M.B. MANCH.,

SENIOR DEMONSTRATOR IN ANATOMY, UNIVERSITY OF LEEDS.

OF the abdominal viscera, by far the most constant in size, shape, and general proportions is the liver, and only very occasionally does this organ depart in form from the standard anatomical description. Owing partly to this and partly to its position in the upper abdomen, the liver is of the utmost importance to the clinician if only as a passive indicator of disturbances in the neighbouring viscera or in the thoracic cavity. Hence the necessity for mapping out the hepatic area in all routine examinations, and for a knowledge of the commoner extrinsic malformations or varieties of this gland.

The most frequent extrinsic anomaly encountered is the well-known Riedel's lobe, a tongue-like downward prolongation of the right lobe, a condition which Riedel thought to be associated with distension of the gall-bladder. Less common, but equally important, is the occurrence of the so-called "floating lobe" in connexion with the left lobe of the liver, which Quain[1] well described as a detached portion occasionally found appended to the left extremity of the liver by a fold of peritoneum containing blood-vessels, and "forming a sort of accessory liver." Such floating lobes rarely produce symptoms, but can give rise to definite signs, recognisable clinically, and may easily simulate abdominal tumours or an accessory spleen. In one such case, described by Inglis,[2] the additional liver lobe formed a pulsatile and expansile tumour in the left upper abdomen, which at autopsy proved to be a rounded piece of hepatic tissue lying in its own capsule quite apart from the liver, to which it was connected by a mesentery about 2 inches in length. The subject was a female lunatic aged 75; the gall-bladder was not distended, and no symptoms could be ascribed to the presence of the additional lobe.

The present case is very similar. In the recent dissection of an obese female subject aged 80, also the victim of chronic mental disease, a mass the size of a hen's egg was detected close to the spleen, and was thought, at first, to be an accessory spleen. Further investigation showed, however, that the mass was a true floating lobe of the liver, to the left edge of which it was attached by a double fold of peritoneum which acted as its mesentery, and, in life, must have permitted great mobility of the extrinsic lobe. The gall-bladder was contracted and the liver otherwise normal.

These floating lobes have a certain, if limited, clinical importance, and are worthy of note. Treves[3] thought them to be associated with gall-bladder distension, but this is not the case. They are always congenital in origin, and are due to portions of hepatic tissue being isolated, as it were, during the great shrinkage of the left liver lobe which occurs towards the end of fœtal life and for some time following birth.

MENTAL DISEASE IN IRELAND.—At a meeting of the Poor-law Commission of the Irish Free State Dr. D. L. Kelly, inspector of mental hospitals, reported that, with the exception of Letterkenny, virtually every asylum in the Free State is overcrowded. There were approximately 1000 patients too many for the accommodation, yet mental disease was only slightly on the increase. He advocated the provision of an auxiliary asylum for every province.

SUSSEX PROVIDENT SCHEME.—This scheme for hospital and specialised medical services appears to be growing apace. Since its inception the following sums have been paid to hospitals: 1921, £332; 1922, £1030; 1923, £3245; 1924, £5501; 1925, £6370. These sums include payments for services rendered at non-coöperating hospitals to members who paid for treatment at any hospital they chose in other parts of the country.

# Medical Societies.

## MEDICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Feb. 8th, Sir HOLBURT J. WARING, the President, occupying the chair.

### RIGHT ILIAC FOSSA PAIN.

A discussion on this subject was introduced by Mr. W. H. CARSON, whose contribution will be found in full on p. 338 of this issue of THE LANCET.

#### *The Medical Aspect.*

Dr. ARTHUR F HURST dealt with the diagnosis of pain in the right iliac fossa due to disease of ileum, cæcum, and appendix. He affirmed that the chief explanation of the numerous mistakes made in diagnosis was want of care, and that a thorough investigation of the whole alimentary tract, or of the whole body, ought to prevent the vast majority of errors. It was desirable to avoid removing an appendix which was not diseased, but it was also important not to overlook chronic disease associated with appendicitis in some other part of the abdomen, which would be revealed by thorough preliminary examination of the patient For example, in 40 per cent. of cases of chronic appendicitis, confirmed by operation, achlorhydria was present. This meant that gastric digestion was not taking place, and so the patient was predisposed to intestinal infection and a variety of complications Appendicitis was also frequently associated with chronic cholecystitis, and if tenderness in the region of the gall bladder had been carefully elicited and the duodenal tube had been used to get some bile for investigation, this association would have been recognised. There was also a frequent association of appendicitis with gastric and duodenal ulcer, and the latter would have been evident on X ray examination. A condition causing right iliac pain which was not mentioned by Mr. Carson was amœbic infection of the cæcum, not only in people who had returned from the East, but sometimes in those who had not been out of this country. In these cases both the cæcal and the liver pain cleared up after injections of emetine. In most of these cases cysts could not be found in the stools, and they did not proceed to abscess formation, but they could be cured by emetine.

The most important help in the diagnosis was that afforded by X rays; by this means it was possible to see the appendix in normal people, and in at least a large percentage of people with chronic appendicitis. For this, however, there must be a proper technique. A radiogram by itself was useless; there must be a screen examination, though as a matter of record a skiagram could be taken too. At the screen examination the physician should be present. Dr. Hurst described by means of a diagram how the tenderness caused by an inflamed appendix could be differentiated from muscle pain, a particular manipulation moving the appendix out of the way for the time being. When an appendix had been removed and the patient still had pain in that region it was often said to be due to adhesions, but he doubted whether adhesions there would cause such pain, or an ileal kink either. It was more likely to be due to the failure of the gastro-colic reflex. He believed it was only possible to diagnose the presence of adhesions by inflation of the colon with air before applying the X rays With regard to the position of the cæcum, in 10 per cent. of normal people it was in the pelvis when they were lying down, and in 25 to 30 per cent. it was in the pelvis when they were in the erect posture; a cæcum in the pelvis, therefore, was not pathological. The trouble was that those who examined pathological people and specimens did not sufficiently examine the normal. In the small proportion of cases in which the appendix was not visualised, all one could do was to see if there was localised tenderness, estimated by moving the cæcal end of the ileum and ascertaining if there was tenderness where the appendix was expected to be. Another condition to bear in mind was tuberculosis limited to the end of the ileum, perhaps just affecting the beginning of the cæcum. These cases simulated appendicitis very closely, but the appendix was not found to share in the tenderness After the patient had been sufficiently long on a carbonaceous diet, if the condition was appendicitis, there was never occult blood in the stools unless there were some such complication as ulceration of duodenum or stomach. Another confusing condition was cæcal and ascending colon stasis, which was sometimes associated with some localised colitis or typhlitis. In such cases removal of the appendix did no good; the patient suffered from various other symptoms besides the chronic iliac pain, and the tenderness was confined to the cæcum and ascending colon. Radiographic examination revealed that the cæcum, instead of being empty after two days, contained a considerable residue of the barium meal four or five days after it was taken. Even when the appendix was secondarily involved in the stasis, removal of it did not cure the pain. But by prolonged medical treatment, massage, and dieting these patients could be made well. Division of bands in this region not only did not benefit, but he had seen patients made definitely worse by that procedure.

#### *The Gynæcological Aspect.*

Dr. T. WATTS EDEN said the gynæcologist was somewhat at a disadvantage in taking part in this discussion, as the organs with which he was specially concerned were either mesial or bilateral, and so there was no reason why disease of them should cause pain on one side more than on the other. It was inevitable that appendicitis must loom largely in this discussion, and it was sometimes associated with inflammatory disease of the pelvis. It was the experience of his colleagues that in cases of chronic salpingitis—which mostly came to operation—the appendix was involved to a greater or less extent, in quite 50 per cent., and in perhaps half the cases operated on for salpingitis the appendix was taken away. There might be merely a thin band of adhesion between the inflamed tube and the appendix. To what extent the involvement of tubes in the appendix caused the pain it was difficult to say, especially as these women usually had many pains associated with their chronic ill-health. When the appendix was not removed the symptoms were sometimes only partially relieved, and when the patient returned a second operation showed the appendix adherent to the broad ligament pedicle, this pedicle consisting of infected tissue. For some time American surgeons had always removed the appendix when they were taking away the tubes. Acute salpingitis was met with under two sets of conditions. The first were those of septic infection from childbirth or abortion; the second was gonorrhœa. In the first of these the circumstances in which the acute abdominal symptoms occurred drew attention to the possibility of the tubes being infected. In gonorrhœa, however, there might be nothing more than a slight discharge to give a clue, and this might not be carefully examined. When salpingitis occurred from gonorrhœa it often came on quite early in the disease. Then there was a sudden acute attack of pain, with fever, vomiting, and constipation, which might closely simulate appendicitis. It might be said that diagnosis was not here of prime importance, since operation would be needed in any case: but this was not so, as the gonorrhœal salpingitis showed a great capacity for recovery. Though eventually the condition became bilateral, one side was often involved some days before the other, and the tubes might retain functional competence for some time. Torsion of the pedicle of a tube might cause a pain simulating that of appendicitis, and an ovarian cyst might twist its pedicle. Until the tube had attained some size it did not come under the influence of the movements of the abdominal muscles which started the twisting.

In these cases the diagnostic difficulties must be very great. He agreed in deprecating the minimal incision in these abdominal operations, because of the desirability of ascertaining the condition of contiguous organs. Cases of ovarian pregnancy had occurred with severe symptoms, and there were records of women having died from burst ovary and hæmorrhage in the peritoneal cavity. Or there might be hæmorrhage into the corpus luteum, usually in a diseased or cystic ovary. In one form the hæmorrhages were multiple. The condition was usually bilateral, but one side was affected more than the other, and the pain referred to the right iliac fossa would often be a very prominent symptom in these cases. They were generally recognised on account of bilateral ovarian enlargement, and associated dysmenorrhœa and perhaps an adherent and retroverted uterus. He concluded by relating a case in which a sewing needle was found transfixing the right ovary. Some time before the patient had swallowed a sewing needle which she had in her mouth, and it was supposed to have passed per rectum; but apparently it had lodged in some part of the pelvic cavity, and as a result of a fall it was jerked into the ovary, where it caused the pain.

The PRESIDENT mentioned a case which he had encountered abroad in which the acute right iliac pain was due to the presence of a collection of nematode worms. In his own experience he was able to say that in the majority of cases in which the cæcum had been brought up from the pelvic cavity and fixed at a higher level the patients had not been benefited. With regard to the X ray diagnosis of chronic appendicitis, he felt that many radiologists had not had sufficient of the experience gained from attending the laparotomy after they had made a diagnosis from the skiagram. In some cases in which he operated for appendicitis he had found that the appendix was not materially diseased, but there was a tuberculous condition of the adjacent portion of bowel.

Mr. J. E. H. ROBERTS congratulated Dr. Hurst on the way in which he was raising the art of diagnosis by opaque meal from a haphazard procedure to a science. Fixation operations for mobile colons answered for a time, but in 12 months the patients were as bad as before. The discussion had emphasised once more the importance of a thorough all-round examination of the patient, rather than examination of one organ by some individual who never saw a disease of any other organ.

Dr. G. W. GOODHART referred to the condition of spasm of the colon, and gave a personal experience. He also spoke of cases in which apparently dysentery had been cured, but the patient suffered for many years afterwards from a good deal of chronic pain in the right iliac fossa; this also he considered to be due to spasm of the colon. With regard to Dr. Hurst's remark, Dr. Goodhart did not think that the fact that a patient's abdominal symptoms were cured by emetine was proof that he had been suffering from amœbiasis unless the amœba was actually found.

Mr. T. H. OPENSHAW said that he had had a good many cases of colitis with appendicitis which were cured with the removal of the appendix. An additional cause of right iliac pain was psoas abscess; another was adherence of the colon or appendix to the external cutaneous nerve. The most common causes of pain after appendix removal were adhesion of the omentum to the scar inside, a commencing ventral hernia, or involvement or ligature of the inguinal nerve during the operation.

The openers briefly replied.

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES.—A special meeting to discuss the Problem of Colour in Relation to the Idea of Equality will be held at the Royal Society of Arts, 18, John-street, Adelphi, London, on Tuesday, Feb. 16th, at 8.15 P.M. The openers of the discussion are Sir Frederick Lugard, the Hon. H. A. Wyndham, and Dr. Morris Ginsberg. Tickets of admission, which are limited in number for members of the public, can be obtained on application to the Director, British Institute of Philosophical Studies, 88, Kingsway, W.C. 2.

# ROYAL SOCIETY OF MEDICINE.

## SECTION OF OTOLOGY.

A MEETING of this Section was held on Feb. 6th, Mr. G. J. JENKINS, the President, being in the chair. The PRESIDENT opened a discussion on

### FRACTURE OF THE BASE OF THE SKULL.

He said his object was to direct particular attention to certain general principles of surgery, rather than to the symptoms, signs, or permanent effects of injury to the parts in which the aural surgeon was specially interested. In all cases, before making a routine examination of the nose and ear, it was desirable to know whether there had been a chronic sepsis of these regions.

*Diagnosis.*—When confronted with serious head injury, even when there was no obvious sign of damage in these regions, the nose and ear should always be carefully examined. Sometimes the evidence of fracture of the base was obscure. Bleeding from the nose in serious head injuries was frequently due to fracture of the skull base, yet it might be caused by an intrinsic injury to the nose. The elimination of fractured base when such nose injury was present might be impossible, and Mr. Jenkins asked that this point might be discussed. He asked whether members regarded loss of smell as a constant accompaniment of fractures which involved the cribriform plate. A posterior hæmorrhage could sometimes be discovered coming from the naso-pharyngeal roof, or a fine stream of blood might issue from the orifice of the Eustachian tube. The examination of the patient should not be considered to be complete until the nose had been searched for gross sepsis.

With regard to fracture involving the ear, when there was destruction of the labyrinth or a lesion of the lower neuron of the seventh cranial nerve, or severe bleeding, or a flow of cerebro-spinal fluid from a torn tympanic membrane or the skin of the meatus, usually there was no doubt that fracture of the base had occurred. When considering injury of the labyrinth one must have in mind the possibility of a severe blow affecting the labyrinth without fracturing the capsule. Injury of the seventh cranial nerve was common, and it was not unusual for the paresis to increase for two or three days after the accident. When blood flowed freely it was very difficult to detect cerebro-spinal fluid in it, though usually this could be done when bleeding had practically stopped. Blood clot sometimes rendered it difficult to make out the details of the injury. In cases of gross injury of the ear there was but little difficulty in making a diagnosis. Mr. Jenkins therefore emphasised the less obvious indications of fracture, and quoted an illustrative case in which the patient, following a fall, had a blackening of the right tympanic membrane, and blood was trickling from the Eustachian tube on that side. He considered that the presence of blood in the middle ear justified the diagnosis of fractured base. A fracture might involve the bony external auditory meatus without rupture of the tympanic membrane or the membranous meatus. In such cases the line of fracture might be indicated by a swelling, sometimes a discoloured line. A comparison with the other ear should always be made; and the presence or absence of chronic middle-ear suppuration should be noted.

*General Management and Treatment.*—Mr. Jenkins stressed the importance of preventing infection and especially of its extension to the meninges. When the nose had been severely damaged there was a temptation to attempt immediate correction of the deformity, but there might be a risk in this if fractured base had not been quite excluded. When fracture involved the ear and there was no bleeding, he advised dropping into the meatus a 2½ per cent. alcoholic solution of iodine, cleaning up the pinna, and dressing aseptically. He did not advise the removal of thin, dry blood in the deep meatus; he preferred to simply fill the meatus with the iodine solution.

Syringing in these conditions he did not favour. Discussing the best procedure when fracture occurred through an ear which was the seat of chronic suppurative middle-ear disease, he said that if there was an obvious escape of cerebro-spinal fluid he would make the drainage of that part as free as possible, even doing a partial radical mastoid operation for this purpose and exposing the dura along the line of fracture in this neighbourhood. In the absence of evidence that the dura had been seriously damaged he would clean up the region at regular intervals, and proceed further as indications arose. His reason for this caution was that operative action might, in the first day or two, cause movement of bone fragments, and so produce damage to the dura.

### *Discussion.*

Sir Charles Ballance said he had never seen hæmorrhage from the internal carotid coming out of the external auditory meatus, except in tuberculous disease of the petrous bone; not from injury. And it was very rare for hæmorrhage to come from the lateral sinus. If this did occur it was liable to be rapidly fatal. Hæmorrhage might come from the middle meningeal artery The chief sources of hæmorrhage in these cases, however, were the vessels of the tympanum and those of the meninges. Efforts must be directed to stopping this bleeding and preventing the supervention of sepsis. If important parts had been interfered with the surgeon must try to secure a return of their function. In some cases of fractured base the hæmorrhage continued for a number of days; in others it had ceased to be important by the second day. Associated with the bleeding there was often concussion and unconsciousness. In that case the earlier decompression was carried out the better it would be for the patient; he had had many cases in which the great value of sub-temporal decompression was demonstrated. Any surgeon who saw such a case should do this operation without loss of time. Of 16 cases in which Harvey Cushing trephined in this way all except two recovered. In cases in which the nose was damaged the same principles of treatment applied. He did not think the nose could be rendered aseptic. Where a fracture occurred across the cribriform plate decompression could be done and sterilised gauze introduced between the brain and the fracture with the object of preventing infection. When fracture occurred through the posterior fossa the injury was much more serious because of its proximity to the vital centres in the brain stem. Hence operation became still more urgent in such a case. When there was a fracture through the base of the middle fossa and blood came from the ear it was the duty of the surgeon to carry out a complete mastoid operation at once, so as to remove all disease and expose the dura, and, if possible, separate the dura from the area which had been infected. Regarding prognosis, he said it was very difficult to know which cases would have meningitis. Sometimes apparently hopeless cases got well. He advised that every case should be treated as if it would develop meningitis. In some cases of fracture through the middle fossa the patient had total deafness and facial palsy. The former might recover, but the latter mostly persisted.

Mr. Sydney Scott agreed that a large number of these fractures involved the middle ear and resulted in middle-ear deafness. In another group there were absolute deafness, destruction of labyrinthine functions and of the cochlea, as well as facial paralysis. Usually severe head injuries with aural symptoms were seen in other departments of the hospital, and the aural surgeon only saw at first the less serious cases. He referred to one case of remarkable recovery. A boy fell 10 feet and was brought in unconscious, bleeding from the ear. Pulpy tissue removed from the ear was found to be brain tissue. A year later the boy was normal and hearing was completely restored.

Mr. A. R. Tweedie (Nottingham) urged the necessity of collecting statistics of hospital cases in which the petrous bone and nasal cavities were involved. He thought active interference in these cases should be avoided, except when primary suppuration existed.

Mr. J. F. O'Malley referred to a case in which loss of smell followed fracture of the base in an air officer who had a crash. In that case hæmorrhage occurred from the posterior fossa. Syringing might be dangerous when the tympanic membrane was involved in a fracture.

Mr. Arthur Cheatle exhibited 23 specimens of fractured base of the skull—17 of his own and 6 from the Royal College of Surgeons. The most common type, occurring in 10 out the 23, was one in which a double line of fracture ran, one through the roof of the meatus, and the other through the posterior meatal wall. Obviously, fractures of the base could occur without cerebro-spinal fluid escaping. Such escape meant a rupture and tearing of the membranes or a fracture running through the labyrinth. He thought it could also occur without hæmorrhage from the ear. In 4 of the 23 cases the fracture had been through the labyrinth itself. In 8 of the 23 cases the facial nerve had been completely divided; in 2 of them that nerve was exposed by the fracture. He considered that the cartilaginous meatus should be purified before anything was done to the deep meatus, as the latter did not contain the number and variety of organisms found normally in the cartilaginous meatus. He agreed that if a fracture passed through a known septic middle ear, operation should not be immediately attempted as it would add to the patient's danger.

### *Exhibition of Cases.*

Dr. Dan McKenzie reported a case of otogenic encephalitis in which decompression resulted in recovery.—Mr. F. W. Watkyn-Thomas gave an account of a woman aged 54 who had necrosis of the petrous bone with unusual complications. Her meatus was found to be blocked by a polypus, and after it had been snared, under gas, she went home apparently well. The same night, however, she had violent vertigo, with falling to the right. Tests pointed to the right labyrinth being active, and a radical mastoid operation was done. The mastoid was eburnated and acellular, and cholesteatomatous debris was found in the antrum and a fistula above the ampulla of the external canal. Exploration disclosed turbid fluid under pressure and pus in the labyrinth. The internal auditory meatus was blocked with blood clot. Drainage was carried out, but the patient did not recover.—Dr. Scott Williamson, who made the *post-mortem* examination, explained his findings: necrosis of the whole of the petrous to the apex, disintegration of the Gasserian ganglion, and thrombosis of the cavernous sinus and the internal carotid within the sinus. There was no infection of the sphenoidal air sinuses.

Mr. Scott described a case of fistula of the semicircular canal, causing vertigo, diplopia, and nystagmus. The patient, a woman aged 25, had had chronic suppurative otitis media for several years, and for six months the insertion of a finger into the left ear caused vertigo. He described in detail the symptoms manifested, and the case was fully discussed.

---

## MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A meeting of this Society was held on Jan. 20th at the rooms of the Medical Society of London, Dr. Wilfrid S. Fox, the President, being in the chair, when a discussion took place on

### *The Diagnosis and Treatment of Urethritis and Cervicitis in the Female.*

Dr. Dorothy Logan, in introducing the subject, said it was her custom to make many examinations in her search for the gonococcus. Certainly at the women's clinics it was hopeless to expect to make a definite diagnosis on first seeing the patient. She examined locally, palpating and expressing the contents of the urethra. Sometimes she obtained ½ drachm to 1 drachm of pus from the latter, when it was not even reddened. Bartholin's glands were also examined, and she used Kusko's speculum for examining the cervix. A bimanual examination followed in order to ascertain what complications were present; and she always took some blood for a complement test. The history given by the patient was received with considerable attention. A statement that rheumatism followed confinement she regarded as significant, as it might mean gonococcal infection. Of 75 new cases, a positive report as to gonococci was returned in only four from film examination, though she felt sure that a considerable proportion had gonorrhœa. Even if a case did not seem very suggestive of the disease clinically she always tried to take three films of it. In a legal case she would not give positive evidence unless gonococci had been actually found, however likely the case was otherwise. Treatment, on the other hand, should not await such positive evidence. She had discovered gonococci in a discharge from the cervix which seemed to be nothing but an excess of clear mucus; also in a discharge which could be described as mucoid, and likewise in a case which had only slight erosion and where there could be obtained only a history of possible exposure to infection two years previously. She was always suspicious of caruncles of any kind. With regard to treatment in a general way, she said she had found vaccines were very useful in the average case. A patient might complain chiefly of pruritus, but there might not be any definite discharge from the cervix or urethra and Bartholin's glands might be clear. Improvement usually followed the use of protargol in glycerine, in packs, and after vaccines the patient usually came back declaring she was quite well. The injections caused little or no discomfort. At a medical discussion she had heard films taken from the vagina described as worthless, but she recently had three cases in which the vaginal film was positive on occasions when those of the urethra and cervix were negative, but later became positive.

Dr. VIOLET RUSSELL said the vast majority of cases of cervicitis were due primarily to the gonococcus. In doubtful cases that organism could usually be demonstrated if looked for on a number of occasions. The most serious damage wrought by the gonococcus was to render the tissues attacked by it susceptible to infection. Urethritis was said to occur secondarily to a *B. coli* pyelitis; this diagnosis, however, should only be made after bacteriological examination had excluded the gonococcus. She had encountered three cases of *B. coli* pyelitis complicating an attack of gonorrhœa without there having been any intervening cystitis. In examining the vulva the burrowing habits of the gonococcus must be kept in mind, and special attention paid to the orifices of Bartholin's ducts, and to the urethra and its ducts. The urethra might seem to be normal, but on milking it a drop of mucoid or purulent secretion might appear, and this rendered the case suspect. A cervicitis presented more difficulties in making a diagnosis, owing to the possibility of sepsis after laceration at a confinement. And there was a class of gonococcal infection in which the cervix was badly eroded, but the urethra was apparently unaffected. Many films must be examined before the case could be pronounced not gonococcal. Sometimes gonococci could not be found until the septic discharge had been cured. The films should be taken from the interior of the cervix immediately after menstruation. Films from the rectum might be positive in a case in which they had been consistently negative from the cervix and urethra, even when there were no signs of proctitis. The diagnosis of gonorrhœa in a pregnant woman might be very difficult, owing to the congestion of the parts caused by their high vascularity. Bacteriology was the safe standby.

Dr. Russell described several types of gonorrhœa. Those of chronic gonorrhœa could be divided into those with discharge but no hyperæmia, those with hyperæmia but no obvious discharge, and those having both congestion and a discharge. The most favourable class for treatment was the first of these; the most numerous class was the third. She said she had seen several instances of mild vaginitis after the use of quinine pessaries. Vaccines she had not found of much service, but injections of collosol manganese sometimes helped. Patients with gonorrhœa should avoid getting hot, as heat increased the discharges. Local treatment required patience and perseverance, and she thought that rapid and certain cure could only be secured in a few cases which came in the very early stage. Dr. Russell described many cases, and detailed the treatments she followed in the various conditions.

The PRESIDENT spoke of two male cases of very severe dermatitis and swelling of the penis following the use by the wives of quinine pessaries.

Dr. FELIX PEDROSO (Brazil) described a suction apparatus for clearing the female genitalia of discharge and residue, which he had used in 3000 cases. In some the discharge disappeared after one use.

Dr. B. B. SHARP insisted that cultures were necessary in these cases, as well as smears, and referred to cases the nature of which was established by doing cultivations when the smears taken had been always negative.

Dr. T. J. WRIGHT (Norwich) said that for obstinate cases of gonorrhœa in the female he found diathermy more useful than any other measure.

Colonel L. W. HARRISON also stressed the fundamental importance of taking cultures for diagnostic purposes, especially as there were many micro-organisms indistinguishable from the gonococcus on smears. In treatment the important matters were good drainage and increasing the patient's resistance.

Dr. DAVID WATSON (Glasgow) had a good word for the examination of smears in diagnosis, especially in expert hands.

Dr. T. ANWYL-DAVIES said his experience was that temperatures even up to 112° F. did not kill the gonococcus, at least in the female.

Dr. LOGAN and Dr. RUSSELL briefly replied.

---

## NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT a meeting held in Manchester on Jan. 15th, when Mr. W. GOUGH (Leeds), the President, took the chair, Prof. H. BRIGGS showed two specimens illustrating the advantages of

### *Vaginal Hysterectomy.*

The first was a uterus (1 lb. 3½ oz.) with multiple fibroids mainly in the lower uterine segment; the largest was low down on the left side and was fixed upon the pelvic floor. The second was a uterus (4 oz.) from a case with first and second degrees of prolapse on a weak pelvic floor. There was glandular erosion of the cervix, and a sessile adenoma and an interstitial fibroid of the body of the uterus. Compared with the size of the normal pelvic cavities in which each uterus lay at a low level, the one specimen was large and the other small. Vaginal hysterectomy had been done in both cases.

Were there any advantages, Prof. Briggs asked, in vaginal hysterectomy for non-malignant uterine growths? This was not, perhaps, a question to be pushed unduly. Dr. Johnson had said that "questioning is not the mode of conversation among gentlemen." For himself, Prof. Briggs was quite content with the success and safety of the operation, where the site and size of uterine innocent new growths pointed towards the pelvic floor. The pelvic floor was a continuation of the abdominal wall and each had its claims. Not infrequently the laxity of the floor was of assistance in performing vaginal hysterectomy, and at the close of the operation the surgeon had an opportunity to correct the defect. This was done in the case with prolapse from which the smaller uterus had been removed. The temperature had once been 100° F. during the first five days after operation, but otherwise there had been normal convalescence and repair.

Vaginal hysterectomy in this (its lighter) phase was bright in prospect and easy in performance. The heavier phase was represented by the first specimen, which was large enough to fill the outlet of the pelvis and stick there pending reduction of its bulk. Morcellement or enucleation, or some equivalent procedure, would convert an impassable ovoid or sphere into a flexible yielding column, whilst the preservation of the pelvic floor must be ensured. Morcellement was conducted on tissues which were to be removed, and they must not be retained at the patient's risk.

After Pean had introduced morcellement in the 'eighties of the last century, it early trespassed, in its excess, on the preserves of abdominal hysterectomy. But the overlapping had not been one-sided. In 1808 Prof. Briggs had published a report of 13 cases of vaginal hysterectomy for fibroids and had confirmed the value of morcellement. Operation by the vaginal route was still consistent with the higher interests of gynæcology.

The PRESIDENT said that in his earlier days he had done vaginal hysterectomy for fibroids, some of which reached the umbilicus. Of recent years, however, he had used the abdominal route for such tumours, because the operation was easier and the work was done by sight. Vaginal hysterectomy, nevertheless, was useful in the treatment of the bleeding uterus about the menopause, for it was associated with much less shock than the abdominal operation. He had found that convalescence was often rather delayed by discharge of pus and small sloughs from the vagina.

Dr. A. DONALD said that at one time he had quite often removed uterine fibroids by the vaginal route. In some of the cases the upper level of the tumour had been as high as the umbilicus. It had been an interesting experience, and he thought that even at the present time a gynæcologist should be familiar with the technique. Now, however, the operation should be reserved for cases of chronic metritis or hypertrophy in women approaching the menopause who had fairly patulous vaginæ. In such cases it might still be indicated. The convalescence was generally a smooth one, and free from some of the discomforts that often followed the most successful abdominal operation.

Mr. M. H. PHILLIPS and Dr. J. E. GEMMELL also spoke, and Prof. BRIGGS replied.

### *An Unusual Monstrosity.*

Miss K. EDGECOMBE, in conjunction with Miss FRANCES IVENS (both of Liverpool), reported a case of dicephalus dibrachius dipus which occurred at the Liverpool Maternity Hospital. The monster, which was born after a long and difficult labour with severe laceration of the perineum, had the following characteristics:—

A double-headed female, weighing 6 lb. 15 oz. There are two distinct heads, two arms, two legs, and a single body which shows, on radiographic examination, two distinct spinal columns approximating in the sacral region.

On dissection it appears that the abdominal and thoracic cavities are single; there is one sternum and two clavicles. There is a single heart and pericardium with one auricle and two ventricles, two aortæ, two pulmonary arteries, two superior venæ cavæ, and one inferior vena cava. The right aorta supplies the right head and upper limb only; the left aorta supplies the left head and upper limb and continues as a normal thoracic and abdominal aorta. There is a trachea from each head leading to four lungs in four pleural cavities. The organs developed from the branchial arches and clefts are duplicated (tongue, thymus, thyroid). The alimentary canal is duplicated as far down as the duodenum. The right stomach opens into the first part of the duodenum; the left stomach into the second part of the duodenum. The spleen is single and in a normal position on the left side. The liver is normal in position. An accessory lobulated portion continuous with the normal liver forms a hernia through the diaphragm and lies in the thoracic cavity posterior to the heart and pericardium. There is a single gall-bladder and bile-duct, the pancreas being double. Below the duodenum the alimentary canal is single. The kidneys, ureters, suprarenals, and female pelvic organs are those of a single fœtus.

As all double malformations develop from a single ovum, there is a single placenta and single chorion.

Following bibliographical and other comments by Miss Edgecombe and some discussion on the labour, Mrs. BARTON HALL (Liverpool), who made the dissection, said that after going through the literature on dicephaly since 1860, when Playfair collected seven cases, she had found 37 published cases from all parts of the world. Studying their anatomy, she had divided them into three main groups dependent upon three stages in the superior dichotomy of the primitive streak. The first group, which was rare, was the true dicephalus dibrachius dipus, of which Miss Ivens's specimen was an example. The second and common group included those specimens which resembled the first group externally, but on dissection or X ray examination were found to have a rudimentary third upper limb in the form of a fused scapula and clavicle. The third group was the true dicephalus tribrachius tripus, and occurred with about the same frequency as the first group. She believed that the lungs and œsophagi in these cases of dicephaly were always reduplicated, and that the extent of the reduplication in the rest of the thorax and abdomen depended entirely upon the level of separation. As to viability, she thought that the greater the degree of separation the more chance there was of the fœtus being viable. One case of dicephalus tribrachius tripus delivered alive had lived 24 days.

Dr. DONALD, Mr. PHILLIPS, and Miss IVENS took part in the discussion, and Miss EDGECOMBE replied.

Amongst other proceedings Dr. J. W. BURNS (Liverpool) described a case of carcinoma of the cervix with pregnancy, and Miss EDGECOMBE—on behalf of Miss IVENS and Dr. R. W. BROOKFIELD (Liverpool)—reported a case of Naegele's pelvic deformity.

---

## BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Feb. 4th, Mr. H. J. WALKER, the President, in the chair, when Dr. DONALD HALL read a paper on the

### *Treatment of Pulmonary Tuberculosis by Artificial Pneumothorax.*

Dr. Hall said that during the past six years he had been successful in establishing an efficient collapse in 15 patients. It was difficult to obtain material, for in hospital practice patients were now under the care of tuberculosis officers and only found their way to the out-patient department accidentally; whilst in private practice most cases were in sanatoriums or under the care of specialists. In this country the treatment had not yet received the recognition which it deserved, for although it was only applicable to some 5 per cent. of cases, it offered them hope denied by any other method. The apparatus he used was that of Vere Pearson and Lillingston; although rather cumbersome in size it was simple and easy to use and easy to keep clean. For the initial puncture he preferred Riviere's trocar and cannula. In the selection of cases not only the extent but also the activity of the disease in the "healthy" lung must be considered. Care must be taken, in acute cases especially, not to produce too high a pressure, and thus incommode the sound lung. Speaking generally, the optimum pressure was the minimum which kept up collapse. There had been a tendency of late to suggest that partial collapse might be preferable to complete collapse. Of this he had no personal experience. In his three cases in which collapse had been incomplete (although therapeutically adequate) it had been impossible to collapse the lung fully owing to pleural adhesions, and so far he had always aimed at bringing about complete collapse. Of this the decisive test was the absence of respiratory movement on the fluorescent screen. In four patients, otherwise suitable, pleural adhesions had baulked him completely. He had met with one instance of embolism, in a patient who was having her last refill prior to leaving hospital for her home in the country. A minute after he had withdrawn the needle the patient had conjugate deviation of the head and eyes and went off into an epileptiform fit. She recovered, but had a permanent hemiplegia, and the treatment was discontinued. Presumably the needle had perforated an adhesion containing pulmonary tissue, for the lung was well collapsed at the time.

Dr. Hall illustrated his paper by cases and lantern slides.

Dr. **NEVILLE COX** said that pneumothorax treatment was necessarily constantly in the mind of those who, as tuberculosis officers, were handling large numbers of cases of phthisis. The difficulty was in defining the suitable cases. Definite evidence of breaking-down lung, as shown by elastic fibres in the sputum, was one indication. Certainly collapse treatment should not be jumped at without adequate trial of other methods, though to defer it too long might be to lessen the chance of success. There was also scope for much judgment during the conduct of the treatment—in deciding the intervals for refills and the pleural pressures suitable to the individual case, and especially in guiding the patient safely through the period of "pleural reaction," when it might be advisable to avoid refills for the time being. When to stop the treatment and allow the lung to re-expand was another difficult question to decide; there were probably many cases in which it was best to continue the refills indefinitely. No sensational figures of successful results were to be expected, but in view of the otherwise hopeless outlook of most of these patients even a small percentage of permanently good results justified the treatment, and in a large number of other patients pneumothorax treatment gave years of useful life, relief from unpleasant symptoms, and lessened infectivity towards other people. There were still a large number of patients dying annually in this country who might have been helped by its timely adoption.

## BRISTOL MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on Jan. 13th Mr. E. R. **CHAMBERS** read a paper on the

### *Ocular Signs of Migraine.*

Visual phenomena, he said, form one of the most constant and striking features of migraine. Often the prodromata occur alone, the usual headache not ensuing; the prodromal symptoms are *not* painful. Temporary blindness, flashes or balls of light, or of colours, are frequently noted.

We have only hypotheses, said Mr. Chambers, to explain these signs. There is clearly a disturbance of function in certain parts of the cerebral hemisphere—probably in the cortex. This disturbance is crude, and appears to leave a transient inhibition. Perhaps vasomotor spasm, leading to anæmia, is the cause; the retinal arteries, at least, are markedly contracted at this period. Many of the visual disturbances resemble the aura of epilepsy, but the two conditions only rarely coexist. Apart from the arterial condition mentioned, examination of the eyes reveals little. The pupils are usually dilated but react; they may be in a state of hippus. The arterial spasm is best seen peripherally in the fundus, and is greater during the prodromal stages than later. The veins are unaffected and Mr. Chambers has not observed arterio-sclerosis. Small central scotoma for white may be found, with a large blind spot for red and green. Various forms of spots, haze, scintillation, balls of light, amblyopia, and other symptoms are reported by patients. As a rule, after such prodromata comes a typical attack of migraine, with subsidence; but rarely the blindness is of longer duration, up to several hours. There is a marked tendency for migraine to run in the family, and Mr. Chambers considers that such severe disturbances can only be explained by circulatory changes from nervous causes, presumably in the occipital lobe. The most interesting prodromal sign is the rare transient homonymous hemianopia. This may appear late in the history of a case after many more typical attacks. Cases of this variety are recorded in which the loss of vision was permanent.

A rare group of cases, said Mr. Chambers, suffer from ophthalmoplegic migraine of Charcot, and in these the paralyses may become permanent. This disease usually supervenes late in the history of a case of migraine, hitherto of ordinary type. The third nerve is usually affected, but the intrinsic muscles escape. Probably these cases should not be classified as migraine. Treatment of migraine from the ophthalmic point of view resolves itself into (1) correction of errors of refraction, which may sensibly lighten the incidence of attacks, but will probably not do more (for it is the *small* errors that affect migraine), and (2) correction of errors in muscle balance. The latter is probably the more important.

Colonel A. E. **LISTER** said that in his experience of migraine the order of the symptoms was sometimes reversed; that is, the typical ball of light was noted in the attacks of early youth, but disappeared in later life.

Dr. J. R. **CHARLES** asked why Mr. Chambers considered that the cerebral cortex was involved in migraine. He himself regarded migraine as due to pituitary swelling; it was known that at times alterations in the thyroid or ovary caused changes in the pituitary. The anatomical relations appeared to favour his view. The vascular and nervous structures, including sympathetic supply in the immediate neighbourhood, would explain the local symptoms, and glycosuria, polyuria, anarthria, and diarrhœa seemed to point to the pituitary. He found that pituitary lesions generally produced not bitemporal hemianopia but homonymous.

Dr. H. H. **CARLETON** agreed that the cortex could not be the site of the lesion, especially if migraine of the Charcot type with ophthalmoplegia was included. This variety could not be cortical. He suggested that pure perception of light was of the nature of a protopathic sensation; vision, as we knew it, was epicritic. Spasm of the ophthalmic artery suppressed the latter and released the former to consciousness. He could not, however, conceive that a pituitary swelling—apart from a gross enlargement—could affect the structures in the cavernous sinus or in its walls. In his experience the hemianopia of pituitary tumour was bitemporal.

Mr. **CHAMBERS**, replying, could not accept Dr. Charles's suggestion that pituitary swelling explained the syndrome of migraine. Nor did he think that the Charcot type was a true migraine. He agreed that blindness might quite well be retinal and not cortical.

Mr. E. **WATSON-WILLIAMS** showed two cases of carcinoma of the vocal cord in men.

---

**HEART DISEASE IN CHILDHOOD.**—At the annual meeting of the Leeds Invalid Children's Aid Society Dr. C. W. Vining said that the society's children's home at Thorparch stood for the treatment of a type of case which had not received enough attention from the medical profession or the public. There was a children's hospital of over 100 beds at the Leeds Infirmary, and the acute case was well dealt with there, but the infirmary could not properly fill the needs of the chronically ill and physically defective child. That was the task the society had set itself, and he hoped that its efforts would be crowned by the State doing more for this kind of case. In particular rheumatic children needed more care. Nearly all heart disease in children was due to rheumatism, and one-half of all heart disease—which caused one-eighth of the deaths in the community—started in childhood. Most of the damage was done between the ages of 5 and 15. If the rheumatic child was properly cared for; if, during the acute phases of the infection it was kept at rest; and if early cardiac cases were given regulated rest and regulated exercise, over months or even years, then the incidence of heart disease and the severity of it would be greatly lessened.

# Reviews and Notices of Books.

### CARDIOLOGY.

*Les Syndromes d'Aortite Postérieure.* By CH. LAUBRY, A. MOUGEOT, and J. WALSER. Paris: Octave Doin. 1925. Pp. 234. Fr.35.

Dr. Laubry and his colleagues have broken new ground in their survey of the clinical manifestations of lesions of the descending aorta. Considering the prevalence of pathological changes revealed post mortem both in the aorta and in its branches, it is surprising that these conditions, apart from aneurysm, should so rarely be diagnosed during life.

The volume opens with a concise description of the morbid anatomy of the different forms of aortitis, illustrated by three beautiful coloured plates. There follows a full discussion of the functional significance of the elastic properties of the aorta, the way in which these properties are modified by disease, and the methods by which the degree of functional impairment can be measured. The next three chapters contain a description of the chief symptoms of aortitis and of the clinical and experimental methods which are of service in its diagnosis. Of the latter, radiological examination and measurement of the velocity of transmission of the pulse-wave are of primary importance. The remainder of the book is devoted to a consideration of the different clinical types of the disease, with a final chapter on differential diagnosis. The clinical features of the various types of affections of the descending aorta are well illustrated by reference to actual cases, and the X ray photographs are convincing, being most successfully reproduced.

Further researches, both clinical and experimental, are needed to simplify what is at present a difficult and a complicated subject; but clinicians, and especially workers in cardiology, will find much valuable information in this book.

---

*Studien zum Problem des Pulsus Paradoxus.* By Dr. L. J. VAN DER MANDELE. Vienna: Julius Springer. 1925. Pp. 80. 7s.

IN this book, to which Prof. Wenckebach contributes an introduction, Dr. van der Mandele describes the types of paradoxical pulse and its relation to clinical conditions. A complete survey of the literature has been made, 145 papers being quoted. The author describes three types of pulsus paradoxus: (*a*) extra thoracic, (*b*) dynamic, and (*c*) mechanical. The extra thoracic is described as of physiological origin and may be demonstrated by compression of the subclavian artery. The dynamic variety is found in certain respiratory, cardiac, and circulatory diseases, such as degeneration of the heart muscle, conditions causing low blood pressure, and pericardial effusions. The mechanical type is best seen in adhesive pericarditis and other adhesive conditions of the chest wall. The author points out that the recognition of this particular form of graphic pulse may be of aid in diagnosis, and the progress of certain diseases may be followed by the appearance and disappearance of the various types. Numerous figures are given of pulse and respiratory tracings demonstrating the types of paradoxical pulse. It is unfortunate that records of the intrinsic heart action have been omitted, for simultaneous electrocardiograms and pulse tracings would undoubtedly be of interest.

---

### BASAL METABOLISM.

By JOHN T. KING, Jr. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. Pp. 118. 12s. 6d.

IN a book of about 100 pages a not very successful attempt has been made to give an account of methods of determining basal metabolism and also of the results in different diseases. Twenty pages are allotted to the study of the anatomy of the thyroid gland and the metabolism in thyroid disturbances, while an account of the effect on the basal metabolism of all other diseases is compressed into eight pages. The book is written primarily for the American public. The Douglas bag method, much used in this country, is not mentioned. From the description of the Tissot method it might be inferred that the way to calculate the oxygen consumption is to subtract the percentage of oxygen in the inspired air from the percentage in the atmospheric air, multiply by the ventilation, and divide by 100. No hint is given that it is necessary to take into account the fact that the inspired air suffers a diminution in volume after leaving the lungs, since the respiratory quotient is always less than unity. Again, the author suggests that in the oxygen "closed circuit" method, which is mostly used in the routine determination of basal metabolism, it is not necessary to absorb the carbon dioxide. Such errors diminish the value of the book.

There is a very complete bibliography which has evidently been compiled independently of the rest of the volume, since many of the references given are not mentioned in the text. This seems to be a fairly common but not very satisfactory custom in recent monographs.

---

### POISONING.

*Murrell's "What to do in Cases of Poisoning."* Thirteenth edition. Revised by PHILIP HAMILL, M.D., D.Sc., F.R.C.P., Lecturer on Pharmacology and Therapeutics, St. Bartholomew's Hospital Medical College; Physician to the Metropolitan Hospital; late Examiner in the University of London. London: H. K. Lewis and Co., Ltd. 1925. Pp. 270. 4s. 6d.

THIS book has stood the test of time mainly because it supplies just what is needed in an emergency, being brief, lucid, and accurate. To have seen 13 editions in 44 years is no mean record for a medical work. Dr. Hamill, who is responsible for this and the previous edition, has maintained fully the object and purport of the work and has been thorough in revision. At the same time he has managed to retain the individuality of the earlier editions for which Dr. Murrell was responsible. In the introduction a complete list is given of the essential contents of the antidote-case which every practitioner should keep handy. To this list should be added a copy of Dr. Hamill's excellent little handbook.

---

### PULMONARY TUBERCULOSIS.

*La Tuberculose Pulmonaire.* Études de phtisiologie clinique et sociale. Second edition. By LÉON BERNARD, Professor in the Medical Faculty of Paris and Physician to the Laënnec Hospital. Paris: Masson et Cie. 1925. With 16 illustrations. Pp. 400. Fr.28.

THIS, the second and completely revised edition of Prof. Bernard's book, presents a series of studies of certain aspects of the tuberculosis problem rather than a detailed exposition of the disease in the usual text-book manner. It does so from the French point of view almost exclusively, and few but French writers receive mention, although warm appreciation is paid to the work of Varrier-Jones at Papworth. Dr. Bernard's creed can be summed up briefly: heredity plays no part, direct or indirect, in the transmission of the disease, contagion being the sole and exclusive factor. Primary infection is glandular, and the child becomes liable to it from birth onwards. The significance of heredity would, therefore, lie in the unbroken chain of infection from forbear to descendant. The mass of the dose will determine the seriousness of the infection and is more likely to arise in the intimacy of domestic circumstances than under casual conditions. The primary infection may produce immunity, either complete or partial. If partial only, there may be recurrence by endogenous reinfection from the primary, hitherto latent, lesion, or from exogenous sources, but these later manifestations of the disease will differ profoundly from the earlier, since, following Koch's experiments, they will not be glandular. The specific defences of the body evoked by the primary infection are now in operation and the disease develops in the forms observed characteristically in the adult.

Terse and epigrammatic, the book makes piquant reading, and there is never any doubt as to the author's convictions. It is refreshing to note that "there are no pre-tuberculous; either men are tuberculous or they are not," for this pre-tuberculous doctrine appears to have attained an importance in tuberculosis that no one seems to claim for its counterpart in measles or mumps. A short but sufficiently adequate description of the signs and clinical forms of the disease and its relation to maternity leads on to an account of methods of treatment. So-called specific treatment, vaccine or serum, is dismissed as utterly useless. There is a careful examination of the conditions necessary in the construction and administration of sanatoria, and the author dispels the illusion that the value of a site for a sanatorium is to be measured by its height above sea-level. Various social factors, family and school life, military service, industrialism and alcoholism are discussed at length. Alcohol favours tuberculosis because of the misery and poverty it brings with it; it hardly seems logical or convincing, however, to urge that the fear of phthisis should be used as one of the most powerful arguments against drink. The dispensary system in France labours under many difficulties, legal and financial; meanwhile the mortality from the disease, in France as elsewhere, is lessening, due, in the author's opinion, to factors involving directly and indirectly the hygienic conditions of man in the mass and collectively. It is like the echo of a long-forgotten controversy to read the pros and cons of compulsory notification. Let France take heart from our example; it is a useful measure and may be adopted without misgiving.

Altogether a delightfully-written book, easy even for the reader with limited French, provocative and stimulating.

---

### CHEMISTRY.

*Smith's Elementary Chemistry.* Revised and rewritten by JAMES KENDALL, Professor of Chemistry, Columbia University. London: G. Bell and Sons, Ltd. 1925. Pp. 442. 5*s.*

THE title of this book suggests just one more of the almost innumerable books devoted to elementary chemistry. However, those familiar with the writings of the late Dr. Alexander Smith are accustomed to expect something out of the ordinary, and here they will find such expectations realised. The book has been entirely rewritten, but it is claimed in the preface that "every effort has been made to leave the volume a characteristic Smith text." The epithet elementary in the title is appropriate only in the sense that the work does not deal exhaustively with every subject it mentions. A very much wider field is covered than in most elementary text-books; thus, in addition to the matter on inorganic chemistry and that on physical chemistry quite an appreciable amount of space is devoted to organic chemistry, including the subjects of plant life and products and animal life, the composition of foods, digestion, and so on. The treatment of many of these subjects must, of necessity, be cursory and in that sense elementary, but he must indeed be a dull reader whose interest in chemistry is not stimulated by the perusal of such a book. Throughout the text no pains have been spared to give practical applications of the principles and processes described, and there cannot be many elementary books on chemistry to which one could refer for information on such varied subjects as gas warfare, fire extinction by foam, high speed and other steel alloys, synthetic plastics, blue-prints, atomic disintegration, and isotopes. Altogether this is one of the most readable books on chemistry we have seen for a long time, and its value is enhanced by the inclusion of a number of very interesting illustrations.

### THE SCIENCE OF HAPPINESS.

By HAROLD DEARDEN, M.R.C.S., L.R.C.P. London: William Heinemann. 1925. Pp. 344. 10*s.* 6*d.*

THIS cheerful book advises us on how to handle our ideas, emotions, and strivings to the best advantage. Dealing with the mind entirely upon the plane of consciousness, with the exception of a short chapter on the subconscious mind and dreams, the author belongs to the intellectualist school of psychology and believes that by taking thought about ourselves we can bring all our mental operations under our own control. So far does he pursue the intellectualist theory that in his consideration of *interest* and *attention* he makes no distinction between voluntary and involuntary attention. On p. 176 he says that "Even the most normal person, if he does not definitely and consciously adopt a 'mental set,' will tend to wander on from idea to idea in this aimless sort of way..." From this one judges that the author believes that our hobbies and prejudices and all the other bees in our bonnets are consciously adopted and can be wittingly altered—a psychology which is no longer generally held. It is when he touches upon the pathological that the weakness of his position is manifest; for example, in speaking of obsessional dreads he advises the sufferer to concentrate on those associated ideas which render that precise object harmless or pleasant for ordinary folk. This sounds easy, but the obsessional patient has usually tried it before he seeks advice.

In spite of these criticisms we believe that the simplicity of the author's psychology will be acceptable and helpful to many people, that the book may do good and cannot possibly do harm.

---

## JOURNALS.

BRITISH JOURNAL OF SURGERY.—The January number opens with Sir D'Arcy Power's nineteenth eponym on Thomas's hip splint.—In discussing traumatic neuritis of the ulnar nerve H. Platt describes three types in which the nerve lesion is associated with recent or old-standing fractures and with recurrent dislocations; he considers that the only satisfactory treatment is the anterior displacement of the nerve.—A. H. Edwards describes a new operation for the repair of the crucial ligaments of the knee.—The radiological and clinical diagnosis of tuberculous glands in the ileo-cæcal angle is discussed by L. R. Braithwaite.—G. P. B. Huddy reviews 109 cases in whom an internal urethrotomy had been performed, and contributes a most instructive paper on the indications, contra-indications, and treatment.—G. Scott Williamson contributes a somewhat fresh view of the problems surrounding the disordered secretions of the thyroid gland.—W. Billington and H. Round report seven cases of successful bone-grafting of the mandible for civil injuries. The graft is taken from the crest of the ilium and is placed in position between the ends of the jaw, and after the wound is healed correct alignment of the mandible is ensured by the use of a dental splint.—A method of completely exposing the radius for excision or drainage is given in detail by A. K. Henry.—Sir Lenthal Cheatle contributes a long paper on epithelial hyperplasias of the breast, in which he suggests that there is a *definite sequence of events in the epithelial changes* in the breast that end in carcinoma, and further he submits that these are identical in time and sequence with those occurring in the skins of men and animals after the application of tar.—Sir Charles Ballance, L. Colledge, and L. Bailey record their results in some further experiments in nerve anastomosis. These comprise two groups, one in which the central and peripheral ends of a divided nerve were implanted into the neighbouring normal nerve at varying distances. In the other group certain nerve trunks were divided and anastomosed in cross-wise fashion. In both the results are encouraging.—F. G. Ralphs records a case of paralytic ileus following fractured ribs treated by ileostomy and recovery.—W. B. Gabriel describes a case of a guillotine amputation stump needing a plastic operation to cover it, a flap being taken in the usual way from the abdomen.—The following rare or obscure cases are described: 1. An unusual complication in operating on large tumours in the neck. The right vagus was stretched over the tumour and had to be dissected clear (H. Halliday). 2. Suppurating thyroglossal cyst (W. E. M. Wardill). 3. Mucous cyst of the tongue (E. I. Lloyd). 4. Rhabdomyoma of the tongue (G. Keynes). 5. Cystic pneumatosis of the small intestine (S. H. Pugh). 6. A case of imperforate anus with megacolon and terminal peritonitis (R. W. Jones). 7. Pulsating goitre with recurrent dislocation of the eyeballs (H. Burrows). 8. Thyroid gland tissue in a dermoid cyst of the ovary (E. H. Shaw). 9. Traumatic rupture of the hepatic duct (S. A. Wallace and A. Spiro). 10. Hernia through the foramen of Winslow with secondary rupture through the gastro-hepatic omentum (E. Rock Carling and A. T. Smith). 11. Acute ascending parenchymatous enteritis causing paralytic ileus (V. Z. Cope).—The pathological atlas deals with some benign tumours of bone.

QUARTERLY JOURNAL OF MEDICINE.—The January number contains the following articles. Heart Failure with Normal Rhythm, by John Parkinson and A. E. Clark-Kennedy. In the majority of cases of heart failure auricular fibrillation is present; failure with a normal rhythm is comparatively rare. A series of 100 such cases has, however, been collected by searching several large hospitals; patients suffering from acute infections, infective endocarditis, or rheumatic carditis in children were not included. The cases were found to fall into certain groups, such as cardio-vascular syphilis, high blood pressure, and chronic lung disease. The prognosis is more unfavourable in heart failure with normal rhythm than when the auricle is fibrillating. An account is given of the pathological changes present in those cases in which an autopsy was performed.—A Case of Malignant Change Developing in a Tumour of the Recto-genital Pouch associated with Diffuse Infiltration of the Lungs and Intense Erythræmia, by Stanley Barnes, A. P. Thomson, and F. W. M. Lamb. The patient, the details of whose illness are here recorded, was an unmarried woman of 28 years, whose chief symptoms were intense cyanosis and dyspnœa. Blood examination showed an erythræmia, but there was no enlargement of the spleen, and no signs of congenital heart disease or of mediastinal growth. At autopsy a diffuse sarcomatous growth was found in the lungs interposed between the alveolar epithelium and the pulmonary capillaries. The primary growth was a small adenomyoma of the recto-genital pouch, which had undergone sarcomatous changes. A plate is included illustrating the histological appearances of the primary growth, an infiltrated lymph gland, and the lungs.—The Blood-fats in Diabetes Mellitus in Relation to Treatment, by A. C. White. There are many conditions associated with an increase of the fats in the blood, and of these the commonest is diabetes mellitus. Investigations were carried out upon 13 cases of diabetes, the majority of which were treated by insulin. The various factors which might influence the blood-fat level are considered, but no definite correlation between them was obtained. The value of the estimation of blood-fats as a prognostic guide in diabetes has not yet been established.—Observations on the Development of Contralateral Disease in Artificial Pneumothorax Therapy, by Maurice Davidson. An interesting account is given of the progress of 22 cases of pulmonary tuberculosis and four of bronchiectasis in whom an artificial pneumothorax was established for therapeutic purposes. In four other cases the diagnosis was uncertain and a pneumothorax was used as an aid to diagnosis in conjunction with radiology. The development of active contra-lateral disease in tuberculosis is a factor which may annul the beneficial effects of an artificial pneumothorax, and the author has made a careful study of the processes which influence its occurrence. Among the conclusions arrived at is that the activity of disease in the relatively sound lung is of far greater importance than the extent of lung thus affected; in acute cases, also, the probability of the disease showing itself in the uncollapsed lung is greater than in chronic pulmonary tuberculosis. Observations were made upon contra-lateral pressures, and excessive pressure due to mediastinal displacement may give rise to ill results entirely remote in their effects. The article is well illustrated by numerous X ray plates.—Nerve Irritation and Aortic Lesions: An Experimental Study, by R. Cunliffe Shaw. Experiments are recorded which were performed upon rabbits to determine the effect of nerve lesions upon arterial changes. The nerves were stimulated electrically or subjected to operative irritation. In the great majority of cases irritation of the vagus or the cervical sympathetic nerves resulted in endarteritis of the aorta. Full details of the nature of the experiments and of the arterial changes found are included in the paper, and the pathological appearances are shown in a series of three plates.—Can Insulin Produce even a Partial Cure in Human Diabetes Mellitus? by G. A. Harrison. This paper was noticed in THE LANCET of Jan. 30th, p. 245.

JOURNAL OF INDUSTRIAL HYGIENE, January, 1926. Under the title of the Thermal Index of Atmospheric Conditions and its Application to Sedentary and to Industrial Life, C. P. Yaglou usefully summarises much detailed investigation carried out in America on ventilation. The thermal condition of the atmosphere being recognised as the determining factor in heat loss and, therefore, of great importance to human comfort, steps were taken to set up an effective temperature index. This was done by recording the sensations of individuals exposed to varying atmospheric conditions. The effective temperature conditions so ascertained were found to be correlated with physiological phenomena, such as body temperature, pulse-rate, blood pressure, body-weight, and basal metabolism. Charts are given showing how the effective temperature can be calculated by varying conditions of air velocity and dry and wet bulb temperatures. When effective temperature is constant the physiological reactions are practically constant. When the effective temperature increases the reactions correspondingly increase. The claim is made that the index found for effective temperatures is more reliable than an estimate by use of the kata-thermometer. Instances are given of practical application in different industries of the method proposed. The treatment by industry of accidents with a view to restoration of function and lessening incapacity is discussed by L. E. Hertslet, who writes from experience in the Transvaal. He points out the financial loss at present sustained, and the value to industrial economics of rehabilitation treatment. He refers in particular to treatment of large septic wounds, of fractures, injuries of the muscles and tendons, of burns, and injuries of the back, and to the value of plastic surgery and of well-constructed artificial limbs. The organisation upon which action should be built is discussed with careful consideration of various methods of modern treatment. His appeal is that industries will find here a sound financial investment, and he is prepared to guarantee a successful issue.

TERAPIA CONTEMPORANEA.—Under this title a new Italian medical monthly has been appearing for some months, edited by Senator G. Pascale, of Naples, and Prof. G. Klemperer, of Berlin, with the help of several hundred of the first authorities of universities in all countries, including Germany, Austria, Italy, France, Switzerland, U.S.A., and Russia. The numbers which have already appeared include original articles by Pascale, Klemperer, Von Haberer, Bectorow, Fuchs, Pregl, and others. The new journal will conduce to the furtherance of the scientific working together of the nations and we wish it the best success.

# Reports and Analytical Records.

## MALVERN WATERS: (1) STILL PURE NATURAL WATER OF MALVERN; (2) SPARKLING "MALVERNIA."

(W. AND J. BURROW, LTD., THE SPRINGS, MALVERN.)

ANALYSIS of (1) still pure natural water of Malvern, and (2) sparkling "Malvernia" (from the St. Anne's spring, Malvern) gives the following results :—

| | (1) Still. | (2) Sparkling "Malvernia." |
|---|---|---|
| Appearance | Brilliant | Brilliant |
| Sediment | Nil | Nil |
| | Parts per million. | |
| Free ammonia | 0·03 | 0 08 |
| Albuminoid ammonia | 0·05 | 0 05 |
| Oxygen absorbed (3 hours) | 0 055 | 0·24 |
| | C.C. per litre. | |
| Carbonic acid gas | — | 4500 |
| | Grains per gallon. | |
| Total solids before ignition | 4·18 | 127·9 |
| Total solids after ignition | 3·78 | 116·7 |
| Loss on ignition | 0·70 (slight browning) | 11·2. (no browning) |
| | Grains per gallon. | |
| Chlorine (Cl) | 0·49 | 48·1 |
| Sulphuric acid ($SO_3$) | Trace | 0·96 |
| Nitric acid ($N_2O_5$) | Nil | Nil |
| Lime (CaO) | 0 7 | 13·48 |
| Magnesia (MgO) | Trace | 7·75 |
| Soda ($Na_2O$) | 0·43 | 12·7 |
| Silica ($SiO_2$) | 0·84 | 0·28 |
| Iron and alumina | Nil | Nil |

The above are probably combined as follows :—

| | Grains per gallon. | |
|---|---|---|
| Salt (NaCl) | 0·82 | 79·2 |
| Calcium carbonate ($CaCO_3$) | 1·26 | 24·1 |
| Magnesium carbonate ($MgCO_3$) | — | 16·1 |
| Sodium sulphate ($Na_2SO_4$) | Trace | 1·8 |
| Silica | 0·84 | 0 28 |

Both these waters are of a high degree of organic purity, as evidenced by the minute quantities of free and albuminoid ammonia and the low oxygen absorption. The still water is very soft and contains only extremely small quantities of dissolved salts. The sparkling water, on the other hand, is very saline, the principal mineral constituents being salt and the bicarbonates of calcium and magnesium. It is well charged with gas and is most pleasant to the palate. The still water is sold in glass-stoppered bottles and the sparkling in crown-corked bottles.

## PYOTROPIN.

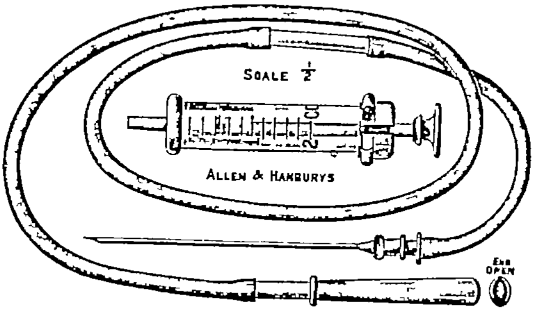
(THOMAS CHRISTY AND CO., 4–12, OLD SWAN LANE, UPPER THAMES STREET, E.C. 4.)

Satisfactory results are claimed for this preparation in cases of lupus, and from Germany in particular a good many clinical records are forthcoming warranting its further trial. The preparation had its origin in Hamburg and has been submitted to us in two forms—namely, a fluid for external use and an ointment. The fluid is a dilution of calcium carbonate with a watery solution of potassium phenolate and a little free carbolic acid. A published analysis of the ointment attributes to it equal parts of salicylic acid and sodium salicylate with sugar, glycerine, and spermaceti. The original idea of the inventor, who was not a medical man, was to remove the marks of tattooing, and the method of treatment being sometimes painful the use of a local anæsthetic is desirable The diseased area is painted with the fluid and covered with a linen rag bearing a thin layer of the ointment, the whole dressing being enclosed in an air-tight plaster bandage. In successful cases there is no suppuration, a dried scab forming and boric acid ointment completing the cure. We understand that Messrs. Christy and Co. will send samples of pyotropin to dermatological departments of hospitals.

# New Inventions.

## A SIMPLE OUTFIT FOR PARACENTESIS THORACIS.

THE simple outfit represented in the accompanying figure has been made after the model of an improvisation used with great success at the French Hospital, London, and in private practice during the last year or two. It should be considered as a portable outfit, made up of a Record syringe with assorted needles that may be used for exploratory puncture of the chest, and provided with an indiarubber tube and teat valve so mounted that evacuation, if judged necessary, can be immediately performed without withdrawing the needle and making another puncture with a trocar fitted to a complicated aspirator. The method is simple. The puncture being made in the usual way, if fluid is found and evacuation is thought advisable, the mounted end of the tube replaces the syringe. The tube is allowed to hang vertically downwards over a basin or jar, and the fluid within the pleural cavity passes slowly and steadily along and drips through the teat valve which at once collapses if, as a result of cough, there is any attempt at back suction. The advantages of the present outfit seem to lie (1) in the simple and effective teat valve, brought to my notice by my late house physician, Dr. Didier, of Mentone; and (2) the standardisation of the tightly fitting mounts with the Record syringe and needles supplied. It is, of course, an easy matter to puncture the chest with the tube already attached (in place of the syringe) to the Record needle, but in such case there must be uncertainty whether or not fluid is present.

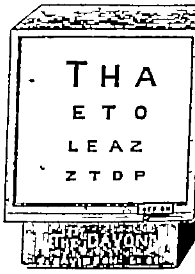


Messrs. Allen and Hanburys, of Wigmore-street, W., are the makers.

F. G. CROOKSHANK, M.D. Lond., F.R.C.P. Lond.

## A PORTABLE VISION-TEST CABINET.

SCHOOL oculists who have to practise in places ill-adapted for their special work often experience great difficulty, especially during the winter months, owing to defective lighting arrangements. The illustration shows an inexpensive portable test cabinet by which this difficulty can be overcome. The cabinet measures 6 in. × 6 in. × 1¾ in., the front being an opal tablet which is illuminated from the back. There are four lines of letters. The illumination is by means of a headlamp and the "Davon" Battery, on which the frame rests and to which it is directly connected. A "make-and-break" contact is provided. The price is £1 15*s.*, or without battery £1 7*s.* 6*d.*



The manufacturers are Messrs. F. Davidson and Co., 29, Great Portland-street, London, W. 1.

W. R. DUNSTAN, M.B. Lond.,
Deputy School Medical Officer, East Sussex County Council.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 13, 1926.

## THE PAYING PATIENT.

It would seem clear that the admission of private patients to the wards, general or special, in our large hospitals is now only a question of time, for when a common expression of public opinion becomes evident its demands cannot be neglected indefinitely. And there is no more doubt of the direction of the public mind. The reasons for this desire for an extension of the in-patient service of the hospitals are two-fold; they are quite obvious and have been set out frequently before. On the one hand, there is a widespread dissatisfaction with the cost of the private nursing homes in relation to the services which they give; and on the other hand, it is becoming more generally recognised that it is only the large modern hospital that can offer the full degree of technical efficiency necessary for the treatment of certain more serious and obscure types of disease. These are the gist of the views expressed in letters published recently in the *Times* and elsewhere, while criticism of nursing homes, a phase of which was dealt with by a correspondent in our columns recently, has been frequent in numerous journals for a long period. It is right to point out that some of that criticism has been unduly harsh. High charges may be high in respect of work done, and yet not high in respect of the cost of that work. The undertakings may be uneconomical, but that is not the same as being grasping. The private nursing homes are often much handicapped by capital charges, and it would be quite wrong to believe that large fortunes are made by their conduct. They may be often the property of one or perhaps two highly skilled and experienced nursing sisters, who have a hard task to contend with difficulties of domestic service, commissariat, and the constant repairs needed by an old and imperfect house, in addition to their essential duties in caring for the sick residents. A study of the budget of such nursing homes would show more frequently than is believed that it would not be possible to reduce charges and make any profit at all, if the endeavour is maintained to render good service. While prices and conditions stay at their present figures nursing homes will remain expensive.

But if nursing homes give much in some cases, and in others cannot afford to give more, it would be idle to defend or ignore the shortcomings of many of these institutions. They cannot replace the amenities of a well-run hospital with its purposive architecture and its special departments and laboratories, and—sometimes a most important point—its resident medical officers capable of dealing with an emergency. The demand for paying wards attached to general hospitals where laboratories and resident doctors are available in convenient buildings is not surprising; it is the logical issue of the developments of medicine running concurrently with altered domestic amenities. That more and more general hospitals in London are considering the provision of such wards and private rooms is well known to the majority of our readers, and the movement is spreading to the provincial towns. It may be added that the rebuilding of many suburban hospitals has recently added materially to the paying beds available in the districts outlying London proper. Some two years ago[1] we published a précis of the accommodation existing for paying patients of moderate means in London; the list then given would have to be extended considerably to give any idea of the facilities available to-day, and it is clear that each year will add to it. We believe that this movement represents a great public benefit, but obviously it is not without its dangers, for it implies certain changes in the conditions both of institutional and private practice that cannot be lightly considered. For reasons which jump to the eyes it is the large and increasing section of the comparatively well-to-do who are left without the best chances of treatment in serious conditions. The devoted attention of their medical advisers enables the majority of them to meet their adversities; it constantly supplies them with a care which could only have its origin in individual knowledge, and for which no institutional treatment will form a substitute. But on the one hand the patients cannot afford the draft upon their resources, and on the other no acute and intimate knowledge of pathological conditions on the part of the practitioner will change an adverse environment or supply costly material. Satisfactory environment and material have been called into existence primarily for the sick poor; how to place them at the disposal of others without encroaching on funds subscribed only for charitable purposes is a problem of great complexity. Admittedly it can only be solved with justice along lines which will ensure that, side by side with the extension of the benefits which the hospitals can offer, there shall be no restriction upon the great functions which called the voluntary hospitals into being and upon which they base their claims to public generosity. Considerable emphasis has been laid on the pecuniary benefit which the general hospitals should derive from this new venture. This is a matter open to doubt. A voluntary hospital, built upon a site which has been bequeathed to it, equipped with costly apparatus through the munificence of the charitable, and staffed by men and women who consent to give their services for negligible salaries, may be able for a relatively small weekly fee to give splendid service to sick persons of the middle classes, while showing on its balance sheet an appreciable annual profit. But it is likely that, if a ward for paying patients is run on such a basis that adequate payments are made for the true rental of the building and the cost of the technical plants and laboratories, the just charge to the paying patients will be far higher than is generally believed, granting the rights of the beneficiaries for whom the charities were founded are to be respected. The protection of these beneficiaries is a problem that has been complicated by a new factor. That the sick poor should, when able, make some contribution to the cost of their upkeep in hospital was a principle difficult to dispute. It is one which has been so famously followed out, individually or upon a group method, that many of our voluntary hospitals, placed among industrial communities, receive large annual incomes in this way. But from the first the danger was seen that the acceptance of that principle might lead to a change in the class of sufferer treated in the wards of our voluntary hospitals. The suggestion has been made openly that the change is arriving, and that the sick poor are less often to be found in our great charitable institutions, their places having been taken by those equally sick but not so poor. Whether this be so or not, its possibility makes every precaution necessary lest the admission of paying patients lead to the catastrophe. The great need here will be the keeping of hospital accounts; and the work now being carried on to ensure that this is done on a uniform plan should be a check on abuse. The large guidance that should be received from accountancy must be remembered if a readjustment of the part played by the voluntary hospitals in communal life is to be equitable.

---

[1] THE LANCET, Nov. 3rd and 10th, 1923.

If the outstanding difficulty attendant on the opening of hospitals to paying patients is that of money, there remain other difficulties exceedingly hard to meet. One of these has always been prominently before the eyes of all medical men. The private nursing home leaves its patients with a complete freedom of choice as regards the services of physicians and surgeons; it is the practice for such patients to remain in the care of their own practitoners, who call in consultant advice at such time as may be deemed wise. What is to happen in the private wards of voluntary hospitals? One of the principles of these institutions has been the personal responsibility of the honorary staff to the governors for all that concerns the welfare of the patients. Is the paying patient to be denied tne services of his family medical adviser, who knows all about his circumstances and his case and who out of that knowledge has advised resort to the paying ward? The honorary staff of the hospital may not care to shoulder responsibility for treatment of patients whose history in unknown save after consultation. Further, one of the principal reasons for the establishment of paying wards is the excellence of the technical attention received by the inmates of hospitals, and the paying patient will enter the ward expecting to derive his share of these advantages. The payment of consultation fees can be arranged, though it is a delicate matter, but, if the appropriate medical duties are furnished by house officers, arrangement for adequate remuneration of their services arises and does not seem to have received the contemplation that it should. We set out points which have been made in these columns and elsewhere on many occasions in order to focus attention on the things that matter. In the changes that are taking place throughout society the position of hospitals, the needs of tne public, and the interests of the medical profession are changing; all should be prepared to adapt themselves to new conditions with a wish tnat any benefits to be secured shall be shared by others. The general position is one of flux, and at best the amalgamation of paying with gratuitous patients will be for a time an experiment. If such a system cannot be perfected, hospitals founded for the use of paying patients will arrive to meet the avowed necessities; in the meantime existing situations have to be met. Modern medicine and surgery are steadily being made available to every class of the community, but the prime reason for the existence of the voluntary hospitals must not be lost sight of nor the valuable relations between the public and their medical advisers be weakened. In the meantime the need for the improvement of many nursing homes seems proven.

## INSANITY—LEGAL AND MEDICAL.

LECTURING last month at University College, London, on Insanity—Legal and Medical, Sir THEODORE PIGGOTT (who lately retired from the Bench of the Allahabad High Court) discussed inter alia the topic of irresistible impulse as a defence to a criminal charge. He explained that two recent decisions of the Court of Criminal Appeal had made it clear that this defence is not accepted by the English courts, though it is widely recognised outside this country, was countenanced by Sir JAMES STEPHEN in his accurate and lucid statements of our criminal law, and was favourably considered by an expert committee two years ago. It will be remembered that Lord Justice Atkin's committee, appointed by Lord BIRKENHEAD in July, 1922, dealt fully with this amongst other matters relating to the criminal responsibility of the insane, and made a specific recommendation that the law should be altered. The British Medical Association had proposed that a person should be held to be irresponsible if prevented by mental disease from controlling his own conduct, unless the absence of control were the direct and immediate consequence of his own default. That was what we may call the medical view of this particular aspect of insanity. The Atkin committee, which consisted exclusively of representatives of the law and the Home Office, agreed that cases of mental disorder do occur where the impulse to do a criminal act comes on again and again with increasing force until it is in fact uncontrollable. These cases, the committee observed, are not within the formula known to law as the rules in McNaghten's case. They added: "We think it should be made clear that the law does recognise irresponsibility on the ground of insanity where the act was committed under an impulse which the prisoner was, by mental disease, in substance deprived of any power to resist." They seemed a little uncertain whether the law in this respect could be changed by judicial decision or whether legislation would be required. As it seems evident that the judges are not going to move in the matter, we should like to know when legislation is going to be introduced. The Criminal Justice Bill, which received the Royal Assent last December, made many changes not only in matters of procedure, but also in matters of principle It was an excellent and unusual opportunity for amending the law in accordance with the committee's recommendation The chance might also have been seized to carry out another similar recommendation of a minor and quite uncontroversial nature—namely, to abolish the ludicrous and illogical verdict of "Guilty but insane." But the chance was missed. The Criminal Justice Act contains not a word about insanity. These omissions are the more regrettable since it is notorious that there is a great gulf between legal and medical ideas of insanity, and that the administration of justice is impeded thereby. The recommendations of the Atkin committee would not have bridged the gulf completely, but they represented an important modification of the legal, out of deference to the medical, view.

The best possible illustration of the divergence of legal and medical opinions upon insanity is furnished by the case of RONALD TRUE, recently republished with an admirable introduction and valuable appendices in the series of "Notable British Trials."[1] The issues in the case were clear-cut; the facts were not really in dispute; the legal doctrines—thanks to the interest taken by Mr. Justice McCARDIE in analytical jurisprudence—were fully examined. The medical opinion of TRUE'S state of mind was unanimous. He had been examined in Brixton prison by Dr. W. N. EAST and his assistant, Dr. YOUNG. His history was that of a man of unbalanced behaviour from childhood, addicted to morphia, and twice the victim of crashes from an aeroplane. After prolonged observation the two doctors were convinced that his was a case of congenital mental disorder aggravated by the morphia habit, and that TRUE was certifiably insane. Two alienists, Dr. PERCY SMITH and Dr. H. STODDART, examined TRUE separately at the request of his relatives. Their conclusion was almost identical. These opinions did not fit the legal view taken by the prosecution, who thereupon had TRUE examined—we are now told—by yet another alienist, Dr. R. COLE. Dr. COLE said his own examination did not disclose anything which justified him in calling TRUE insane, but he gave his opinion subject to several important reservations. Sir RICHARD MUIR, who prosecuted for the Crown, thus entered upon the trial without the support of a single expert who would say that the accused was a sane and responsible man He relied upon the legal view of insanity, contending that TRUE clearly knew the physical nature of his act in killing GERTRUDE YATES, knew that the act was wrong, and was therefore within the law as laid down for the past 80 years. Sir RICHARD MUIR so ably and tenaciously conducted the case that the jury found the prisoner guilty and their verdict was upheld by the Court of Criminal Appeal. From that point, however, the tide turned in favour of the medical opinion. The medical evidence had been sufficient to put the Home Office upon inquiry This being so, it was the duty of the Home Secretary to have the prisoner examined by two or more doctors in accordance with Section 2 (4) of the Criminal Lunatics Act, 1884. Mr. SHORTT appointed Sir MAURICE CRAIG, Dr. SIDNEY DYER (then medical member of the Prison Commission), and Sir JOHN BAKER (formerly medical superintendent of Broadmoor). They found TRUE to be undoubtedly insane and the execution was, as the common law enjoins, respited. The man who was sane enough to be sentenced to death was not sane enough to be hanged after all.

---

[1] Trial of Ronald True. Edited by Donald Carswell, of the Middle Temple, Barrister-at-law. William Hodge and Co., Ltd. 1925. 10s. 6d.

In TRUE'S case not only the jury but a large section of the public took the legal rather than the medical view. When it was announced that he was not to be executed an amazing outcry arose. Only a day or two earlier, as it happened, a youth named HENRY JACOBY had been hanged for the murder of Lady WHITE. The newspapers were full of angry protests. JACOBY, it was said, was a poor working man's son who had killed a rich knight's widow and therefore had to be hanged, while TRUE, a well-connected man who had killed a poor outcast, was reprieved. The courts of law, it was said, had been flouted; trial by jury had been superseded by trial by Harley-street. The Home Secretary was violently attacked, but made an excellent defence in the House of Commons, and eventually the storm subsided. Out of these events came ultimately the appointment, report, and recommendations of Lord Justice ATKIN'S committee. It is because those recommendations did something to reconcile the differences between the legal and medical view of insanity—differences so unfortunately emphasised in the case of RONALD TRUE—that we press the question, "When will the recommendations be given statutory effect?"

## THE MENTAL EFFECT OF PHYSICAL DEFORMITY.

THE desire to appear normal, to say nothing of attractive, in the eyes of our fellows bears the marks of an instinctive process. The extent of its development varies both racially and individually, and visible defects may accordingly be invested with an emotional value dependent upon the reaction between two variables—the attitude of the multitude and the sensitiveness of the individual. Not all of us who need it can claim the equanimity of that American statesman who retorted to a commiserating friend by a verse, cast in a popular form, briefly explaining that his lack of beauty concerned himself not at all, but jarred only the beholder, and even such equanimity would fail if the defect were of a kind to excite strong aversion. It is in recognition of this fact that facial wounds received in the late war are assessed for pension purposes not merely upon the degree of loss of function, but also upon the degree of disfigurement; in legal cases the same consideration has full weight. Though people of similar training and prejudices might reach a general agreement as to the effect upon the beholder of a particular disfigurement, yet this agreement would only indicate the reaction of the herd; the sensitiveness of the sufferer cannot be expressed as an average, and extreme and unexpected variations are actually found. In some cases where a definite organ, as an eye or a nose, has been lost the patient's reaction takes the form of a feeling that the personality has suffered some grievous loss; the patient, if given the opportunity to express himself freely, complains neither of defect of function nor of actual deformity, but rather of feelings of inferiority in the presence of other people, of a loss of personal values and pleasure in life, plainly attaching to the missing organ a significance out of proportion to its physical importance. It may be assumed that unconscious determinants are at work in producing this mental attitude which, however irrational it may be, provides a strong incentive to cosmetic endeavour.

The sense of inferiority thus induced by the loss of an organ reaches its height when the external genitals are concerned, and Prof. ARTHUR EDMUNDS, in the Hunterian lecture reported in this issue, describes an operation for hypospadias which finds part of its justification in the mental reactions caused by the deformity, though there are, indeed, straightforward physical reasons for the effort to relieve this congenital defect. These Mr. EDMUNDS indicates, referring also to the social reasons that strengthen the call for operative interference, and one must admit cause for the fears that led the parents of one child to hide the knowledge of his deformity, though their policy of seclusion might itself have exaggerated other mental results. The genital organs carry such an emotional charge that, even though they remain concealed in ordinary circumstances, the reactions of the individual to any loss or defect are often greater than when he bears a loss literally upon his face. There come into play not only the unfortunate attitude of the herd to the individual, but the reaction of the individual to the awareness of his own misfortune. Moreover, in the case of children we must bear in mind that mental development in the psycho-sexual sphere is so powerful in determining the whole behaviour of the individual that, apart from endocrine influence, the physical state of the genitalia as they appear to the person concerned must play a part, though its extent may be debatable, in fashioning his reaction modes and character traits. It is known that vulgar nursery threats of mutilation have formed the nucleus of unconscious motivations in the direction of fear or hatred. It is not unduly speculative to apply these considerations to the subjects of hypospadias; for, when the mere threat of loss of the penis can produce pathological results through unconscious mental processes, we should expect that, even if a happy fate shielded the sufferer from unkind comment, an actual defect would contain disastrous possibilities in regard to mental development.

These a priori views can only be tentative, for there seems to have been no systematic study of the mental states of the subjects of extreme degrees of hypospadias. There can be no doubt, however, concerning the relief from social disadvantages that a successful operation can bring, and the consequent saving of physiological distress is undeniable. Whether deeper feelings of deprivation can be prevented or abolished, and whether the liability to perversion mentioned by Mr. EDMUNDS can be obviated, are questions that can only be solved by psychological investigation. There remains the question of marriage, and though in mild cases operation may render satisfactory the full sexual function, yet in the cases described as pseudohermaphroditism the results must fall so far short of the normal that the risk of unhappiness would render marriage an experiment not to be lightly attempted. But a patient who has reached adult life, surgery having done its best for him, may be presumed to have acquired sufficient knowledge to face his own difficulties.

◆

## A COMMITTEE ON VACCINATION.

AT the International Conference on Small-pox recently held under the auspices of the Health Committee of the League of Nations (see THE LANCET, Jan. 30th, p. 243) certain conclusions were arrived at as to the methods of investigation to be adopted. These included inquiry into the essential matters over which Government control of vaccine lymph should be uniformly exercised and into the relative value of various tests devised for the estimation of its potency, and study of the affections of the central nervous system which have been reported to have followed vaccination in some countries. No time has been lost by Mr. Neville Chamberlain in responding to the suggestion made at the conference that various Governments should collect and study relevant information. It is announced that the Minister of Health, in conjunction with the Medical Research Council, has appointed a committee to inquire and report from time to time: (1) on matters relating to the preparation, testing, and standardisation of vaccine lymph; (2) on the practical methods which are available in the light of modern knowledge to diminish or remove any risks which may result from vaccination; (3) on the methods of vaccination which are most appropriate to give protection against risk of small-pox infection in epidemic and non-epidemic periods. The committee will also be charged with the duty of coördinating the work of investigation on these questions in this country and abroad, having regard to corresponding work undertaken by international health organisations. The committee consists of Sir Humphry Rolleston (chairman), Dr. F. R. Blaxall, Dr. G. F. Buchan, Dr. A. E. Cope, Dr. Mervyn H. Gordon, F.R.S., Prof. J. C. G. Ledingham, F.R.S., and Dr. J. R. Perdrau. Its secretary is Dr. J. R. Hutchinson, a medical officer of the Ministry of Health, Whitehall, S.W. 1, to whom all communications relating to the work of the committee should be addressed.

# Annotations.

"Ne quid nimis."

## MALARIA TREATMENT OF CEREBRAL SYPHILIS.

THE history of the attempts to treat such an intractable disease as established cerebral syphilis makes sorry reading. Prof. Warrington Yorke, who discussed the Malaria Treatment of General Paralysis of the Insane at a meeting of the Liverpool Medical Institution held on Feb. 4th, dismissed modern specific antisyphilitic treatment, including intrathecal medication, as little more effective than the older treatment with mercury ointment against neuro-syphilis. He had some hope, however, that tryparsamide might prove to be as effective in syphilis as it has been in sleeping sickness. With regard to non-specific treatment, he recalled the fact that Hippocrates and Galen knew that fevers influenced psychoses, as also did Boerhaave and Sydenham. As long ago as the middle of the nineteenth century attempts had been made to produce changes in cases of G.P.I. by the induction of abscess formation and similar processes. Later there followed in succession treatment by the injection of non-bacterial substances, such as milk, then the use of vaccines, and ultimately in 1917 the injection of living micro-organisms. In 1920 Wagner-Jauregg, in Vienna, published the results of the treatment of a series of cases infected with malaria. The technique was comparatively simple, the blood from a malarial individual being introduced into the patient either intravenously, intramuscularly, or by scarification. The investigation of 400 cases treated in Vienna during the years 1917 to 1922 showed the following results: complete remission 33 per cent. and partial remission 14 per cent. In a series of 299 cases treated in 1922 in five large British mental hospitals, 70 patients had improved to such an extent that they could be discharged from hospital. In a series of cases in the pre-asylum stage complete remissions were obtained in over 30 per cent. The latter group obviously contain a larger proportion of cases in the early stage of the disease. It is unfortunate that in many cases the condition is only arrested and the victims still remain useless members of society. At the same time many such cases become cleaner in their habits and consequently easier to nurse. It is impossible yet to forecast the ultimate result of malarial treatment, except that greater success can be hoped for in early cases. In some patients the improvement is immediate and dramatic, whereas in others it is slow and may go on for months. As regards the effect of the treatment on the serum and cerebro-spinal fluid reactions, these may become normal, but in many cases are not parallel to the clinical changes; clinical improvement may be complete and the pathological reactions remain unchanged for a considerable period and only after many months gradually move in the normal direction. Several pathologists have had the opportunity of examining the brains of remitted cases who have died from intercurrent disease; some of them showed no changes recognisable post mortem as those of G.P.I. The treatment requires some judgment and considerable experience; especially difficult is the decision as to when the attacks should be stopped. If they are stopped too soon, no benefit ensues; if they are allowed to go on too long, the patient may die. There are no means of modifying the severity of the attack; the premature administration of quinine completely spoils the results and also prevents reinfection for a period of many months. Prof. Yorke advises 8 to 12 malarial attacks as the optimum number in the majority of cases. He spoke also of the interesting opportunity that treatment of these cases had given of studying closely the phenomena of malaria. He pointed out that in these induced cases very few doses of quinine sufficed apparently to cure the patients, in contrast with the difficulty of producing this result in ordinary tropical practice.

It had been possible to establish definitely the existence of three species of malaria parasites, the parasites of each species always breeding true. In the induced cases relapse was comparatively rare, and when it did occur was long delayed. The ineffectiveness of quinine to cure the war cases and patients in tropical practice was due to the fact that they were not primary infections. The factor which governed relapse was the patient's individuality; the occurrence of relapses was in no way related to the strains of parasites with which the patients were infected, or to the drugs used, their dosage and their method of administration. He advanced a hypothesis of the process by which quinine indirectly destroys the parasites, and concluded by pointing out not only the uselessness but the actual danger of either too large doses or of too long prolonged administration of quinine.

## THE FACTORY CODE.

MODERN industrial methods were born in this country and so was factory legislation. As a nation we may hesitate to-day between some legitimate pride over a legal code which has been taken as a model to be imitated throughout the world, often even imitated slavishly to the letter when the circumstances demanding some enactment do not exist, and deep-seated shame over the conditions of human life which stimulated the national conscience to embark upon this uncharted sea. The whole story of this voyage of adventure during last century, of how out of the eater came forth meat, is not retold in a book by Mr. H. A. Mess, entitled "Factory Legislation and its Prevention, 1891–1924,"[1] which lies before us; the thread of the narrative is only taken up where others have left it at the end of last century and brought up to date. The year chosen for the start is 1891, when power to control dangerous trades by special rules first became statutory, a power upon which remarkable codes, revolutionising health conditions in many industries, have been built; this period witnessed a great trade union revival, the return of the first Labour Member to Parliament, and the first International Labour Conference. Henceforth, legislation up to the war period was directed at particular objectives rather than at such sweeping reforms as limitation of hours of labour, a matter upon which statute to-day lags far behind practice; the lead industries are controlled, phosphorus poisoning is abolished, anthrax is tackled, dust inhalation is studied, humidity in cotton mills is investigated. At each stage the tendency becomes more and more pronounced to proceed after inquiry based on scientific evidence, rather than in answer to nebulous popular demand Two reforms can be quoted. The first is that children have disappeared from factories; the second, which has crept in insidiously, is that adult males, previously omitted from all protective legislation, were brought within the scope of special regulations. The war period marked a new era of which the maintenance of health is the guiding star, rather than the prevention of disease; the Health of Munition Workers' Committee strove to increase output to meet national emergency and based its advice on the results of scientific investigation. Power to make welfare orders was taken and has been widely used; the safety-first movement followed. And we are brought up to date with a vast amount of complicated and piecemeal legislation waiting to be amalgamated into a consolidating Act—now long overdue. Mr. Mess describes international action in the period under review, and the coming into being of the International Labour Office; the way law is enforced and new ideas spread by the staff of factory inspectors; the creation of Whitley councils; and other kindred legislation, concerned with such things as compensation, wages, national health insurance, education, and housing. Further extension of factory legislation is held to be inevitable as scientific technique alters, and as, through research, more accurate knowledge is obtained of the human factor in industry and of its reactions to hours of labour and to such environmental influences as light, temperature, and ventilation. Such extension and research must call more and more for skilled medical work. Altogether the book, which contains a useful bibliography and is well indexed, is a careful and accurate résumé, clearly written and informative. It must be invaluable to anyone interested in that great branch of public health legislation—the factory code

## CLIMATIC BUBO.

So many cases of climatic bubo have been seen in the Hamburg Hospital for Seamen during 1924 and 1925 that Marinestabsarzt (Surgeon Lieut.-Commander) Reinhard Günther was led to discuss them in the *Archiv für Schiffs- und Tropen-Hygiene* for October, 1925 (p. 510). He says this bubo has been described over and over again, ascribed in turn to malaria, dysentery, plague, trematode infection, and rheumatic fever, but is now considered in itself a distinct disease and due to infection; and while the infecting agent and the point of entry remain unknown, he suggests a probable venereal origin. Climatic bubo occurs in all tropical and subtropical regions, but also in people who have never left Europe. It attacks the glands in the groin almost exclusively, particularly the deeper glands, and, histologically, it differs from inflammations due to pus-forming cocci, for the gland capsule is thickened, the reticulum is cirrhosed, and the cells within the meshes degenerate. There is no general suppuration of the gland; bacteriologically the pus is sterile to culture and to microscopic examination (whether direct or dark ground), and inoculations of all kinds into apes, guinea-pigs, and rabbits have been negative. Six cases in all were admitted to the Hamburg Hospital for Seamen in 1921–2–3, but in 1924, 15, and 14 in the first eight months of 1925. Of the total of 35 cases, nine came from Java, six from East Asia, six from Africa, and five from South America; 15 were left-sided, 9 right, and 11 double. The ages of the patients fell between 18 and 41, usually in the twenties. Out of 30, three were officers, 16 came from the engine-room staffs, and there were 11 others. The general condition of the patients was good; they had slight pyrexia, pulse varying with the temperature, and there was no swelling of liver or spleen. The glands might be the size of a walnut or of the fist; they enlarged slowly, the deep glands enlarging first. In two-thirds of the cases the pelvic glands also enlarged, in one case so much that disease of the pelvic bones was feared. Periadenitis was rare, lymphangitis was always absent, abscess formation was focal, not massive, and the foci rarely coalesced. If the small abscesses burst through the skin the openings remained separated, with normal skin between. The course of the disease was slow and the inclination to recovery slight, but the period under treatment is not recorded. No venereal lesion to account for these buboes was ever found, but two patients had scars of old hard sores, two had positive Wassermann reactions. Iodine by the mouth and warmth or ice locally, with rest in bed, cured three early cases, and three more recovered after puncture-incisions; two cases got well after X ray treatment, incisions were needed for 23, and excision secured good results in four cases.

Two papers on this disease appeared in 1925 in the *Annali di Medicina Navale* from the pen of Captain (Surgeon) Dr. F. Virgillo, one in January (p. 1), the second in May (p 268); in these it is called "subacute lymphogranuloma of the groin." In the January number the literature of the disease is discussed at length, and it is stated that this swelling arises rapidly, that it usually suppurates and forms sinuses, and that it always ends in a satisfactory cure. It is held identical with the "climatic bubo" of many authors, and while its ætiology is not determined the probable origin is held to be venereal. Clinical reports of seven cases are given, all in males of 21 years of age; one was ascribed to strain, one was associated with gonorrhœa, four patients had small preputial abrasions of which they declared themselves unaware, and one had a small ulcer on the leg. There was no characteristic blood picture, this according with Dr. Günther's observations. Three patients gave a negative Wassermann and a negative cutaneous reaction for tubercle. The pus was sterile and attempts at inoculation all failed. Some of these buboes became reduced under ice-bags, some with iodine injections; excision was useful. Treatment lasted from 35 to 110 days. The glands when removed had a thickened capsule, the reticular strands, too, were thickened, the cells on them proliferating; the gland cells were thus compressed and coagulation necrosis was occurring—two large microphotographs illustrate these changes.

## FLY PREVENTION IN THE TROPICS.

ON the West Coast of Africa, with its torrential rains, night-soil disposal is limited to earth disposal in deep pits, since incineration and water carriage are impossible, as is also shallow trenching. In these pits flies develop in their tens of thousands, and tend to escape in large numbers when the pits are opened to make fresh deposits. In the January number of the *Journal of the Royal Army Medical Corps* Major A. L. Otway describes a method whereby the flies were reduced to a negligible quantity. He found that flies, newly developed in the dark, make directly for the nearest point of light. He therefore kept the pit completely dark, admitting light at one point only, far from the filling orifice. He fitted a fly-trap over the point of light, and caught the flies there. The pits are about 20 ft. long, 12 ft. deep, and 4 ft. wide, roofed over with bush timber, palm leaves, and beaten earth tarred or treated with heavy oil, to shut out the light. A filling orifice is made of a sanitary dustbin without a bottom, but with a well-fitting lid, over which is a loose tarred canvas cover through which the handle projects. The fly-trap is an 8-gallon petrol tin case, about 20 in. by 10 in. by 14 in.; its top is replaced by copper gauze, and similarly protected windows are made in the sides, while a 6 in. circular hole in the bottom gives access to a gauze cone, 5 in. high and 3 in. across the top. The whole is set on an opening in the roof of the pit. Over the pit, 2 ft. away from it all round, is a thatched weather protection—light over the trap, dark over the supply opening. The first trap set up became almost immediately filled with flies; many of these were dead five hours later. If they have no way of escape to find food they die, at any rate they do not breed. An immense number of flies, estimated at 250,000, have often been caught in a week. The trap can easily be changed at night, and if it is placed far from the filling orifice, and that is kept dark, few escape. There is no offensive odour, so that the pit need not be kept a long way from dwellings. The number of flies in the area is said to have become negligible since this method of attack has been instituted. But success evidently depends largely on minute exactitude in carrying out the details of the procedure recommended, and medical officers in the tropics who wish to give the method a trial would be well advised to consult Major Otway's article.

## RETROPERITONEAL CYSTS.

ACCORDING to Dr. Henry W. Cave,[1] of New York, who records an illustrative case, retroperitoneal cysts, though of infrequent surgical occurrence, are of considerable importance from the embryologico-anatomical standpoint. Most of the cases have been recorded in foreign literature. It is generally agreed that the cysts spring from some portion of the developing urogenital tract, or from some variation in the developing retroperitoneal lymphatic system. The growths, which may be single or multiple, have been classified as follows: (1) the single unilocular cyst; (2) the single cyst with smaller daughter cysts arising from its wall or cysts in the large cyst cavity; (3) a mass of cysts of approximately the same size without any connexion between them; and (4) multiple cyst adenomata. The wall is composed of fibrous tissue and the lining membrane may be loose or close connective tissue without epithelium. The contents are lymph, blood, jelly-like pseudomucin, or colloid; hair, teeth, or grumous material; parasitic elements; or a combination of two or more of the above. The most frequent symptom is either a localised or a general increase in the size of the abdomen, or occasionally localised pain or pain referable to pressure on the dorsal nerves. Sometimes, but rarely, there are œdema and varicosities of the lower extremities. Bladder symptoms may arise owing to pressure as the tumour enlarges in an upward direction; pressure on the bile-duct may give rise to jaundice; or disturbance of respiration may develop. There may be loss of weight and cachexia, especially if the cyst be malignant. A retroperitoneal cyst is rarely diagnosed before operation, being usually mistaken for one of the following conditions: ovarian cyst, hydronephrosis, renal tumour, or tuberculous peritonitis. In most of the cases the correct diagnosis is made in the course of an exploratory operation. The prognosis is good, recurrence being exceptional. The treatment does not involve any complicated procedures, enucleation or marsupialisation in one or two stages being all that is required. Dr. Cave's case occurred in a boy, aged 3 years, in whom the symptoms were a definite increase in the size and prominence of the abdomen, especially on the right side, and loss of appetite. A pre-operative diagnosis of tuberculous peritonitis was made. On laparotomy a huge retroperitoneal cyst was found pushing the cæcum, appendix, and transverse colon up under the liver. As the patient's condition did not allow much manipulation, it was decided not to remove the entire cyst but to evacuate the contents and establish drainage. About 850 c.cm. of dark red fluid were drawn off from the cyst, within which two daughter cysts were found, from each of which another 150–175 c.cm. were removed. After a stormy convalescence complete recovery took place.

## PUBLIC HEALTH IN JUGO-SLAVIA.

Dr. Alfred Greenwood has given the Kent County Council a very interesting report of a visit to the kingdom of the Serbs, Croats, and Slovenes, which he paid last summer under an arrangement made by the League of Nations and the Rockefeller Foundation, for the international exchange of public health officers. In the sixth of a series of articles on the machinery of public health administration abroad[1] we recently gave an account of the medical organisation of Jugo-Slavia from which it was clear that the health services of that country are in many ways rudimentary. This is certainly true; but what fills Dr. Greenwood with amazement is the remarkable progress of the last few years—progress which he thinks is unparalleled in the public health history of the world. The health department was only set up six years ago, and it is probable that its rapid development has been made easier rather than otherwise by the fact that old Serbia had no traditions in hygiene. During the war that country lost a million men, and the shortage of doctors became acute. In Jugo-Slavia there are now, however, 3000 doctors to serve a population of 12 million, and, thanks to the foresight and enthusiasm of the chief medical officer, Dr. Stampar, there are 150 whole-time specialists in public health as well as 300 part-time officers, and the number is steadily increasing. It is astonishing to read of the school clinics, tuberculosis dispensaries, venereal clinics, malaria stations, research and bacteriological institutes, maternity and child welfare centres, treatment centres for trachoma, and the hundred-and-one other results of a few years' endeavour. There is active welfare work in the schools (where there are some 850,000 pupils), and Dr. Greenwood says that "the treatment of defects found amongst elementary and secondary school-children in Belgrade seems in advance of our own arrangements." In the country districts there are mobile units for dealing with epidemics, and a determined effort is being made to stamp out malaria. A laboratory for research in tropical diseases was established at Belgrade in 1922, and the lowlands by the river have been carefully studied with a view to fighting mosquitoes. Chlorine gas is giving successful results. An institute of social medicine in Belgrade includes amongst its activities biometry, the study of hygiene in its application to the needs of different parts of Jugo-Slavia, and the dissemination of information to the public. Propaganda is thriving, and throughout the country there is a wave of interest in health which had led to the erection of institutes and laboratories everywhere. The housing conditions, however, especially in Southern Macedonia, are often deplorable, and Dr. Greenwood considers that more nurses and health visitors are needed. No one knows how long the public enthusiasm will last, but what has already been done sounds almost miraculous to anyone familiar with the state of the Balkans before the war, and Dr. Greenwood's report deserves wide circulation

## ELECTROLYTIC DISINFECTANT FLUID.

When Faraday in 1833 wrote "On Using Solutions of Chlorides in Water—for instance, the Chlorides of Sodium or Calcium, there was evolution of chlorine only at the positive electrode, and of hydrogen, with the oxide of the base as soda or lime, at the negative electrode," he probably no more expected that about 70 years later a medical officer would propose to his authority to utilise this discovery for the manufacture of disinfectants than he did that the last section "On the absolute quantity of electricity associated with the particles or atoms of matter" of the same paper would lead to the actual determination of this quantity and of the mass of the atom itself. Dr. F. W. Alexander, in a special report on "Twenty Years Working of the Electrolytic Disinfectant Plant of Poplar," describes in untechnical language his work on the production of a stable disinfectant by electrolysing a mixture of chlorides of sodium and magnesium. He frankly states that he is not a chemist nor an electrician, and there is no difficulty in accepting this statement. He is evidently a painstaking experimenter who, in the midst of many other duties, has worked out a practical means of carrying out an idea and has exploited his product with all the ardour of the pioneer. The use of chlorine obtained by electrolysis as a disinfectant, as Dr. Alexander shows, is not new. The merit of his preparation is that he seems to have produced a hypochlorite solution relatively free from chlorate and rendered stable by a slight excess of base, the presence of magnesium salts in the solution preventing so large an excess as would render the liquid inactive. Actually Dr. Alexander has used magnesium hydroxide as a stabilising base but, as he points out, soda should be equally efficacious. An interesting part of the report deals with the very difficult question of swimming baths. Dr. Alexander describes very fully the many unpleasant ways in which these otherwise excellent institutions become contaminated and may thereby spread infection. Anyone who has visited the outdoor and indoor swimming baths in and around London must feel that they are sources of pleasure and, in the main, of health to hundreds of thousands, and yet that the risks of bathing in the highly concentrated extract of human surfaces are not altogether to be ignored. The remedy is not clear. Dr. Alexander advocates the use of his own hypochlorite disinfectant and, where it can be afforded, filtration. Open-air baths are favourably situated for the action of air and light on the water and on the skins of bathers. The water of these baths is usually well aerated owing to the rapid growth in the bathing season of green organisms. These minute plants abstract the $CO_2$ from the bicarbonate in the water, retaining the carbon as body substance while the freed oxygen goes into solution. The calcium carbonate falls to the bottom as mud and the water becomes softer and more alkaline. The larvæ of midges are usually plentiful, and frequently water-beetles, and particularly the water boatman, forced to escape by flight from drying up ponds, thrive in such baths. The use of disinfectants stops all this but does not clean the water. Filtration removes suspended matters and gives an extremely clear, bright liquid. It does not sterilise the water. Disinfection and filtration yield a clear and sterile liquid, but it is difficult to feel that this is as good as fresh water, which is costly. The continued use of such a "cleaned-up" liquid must lead to great concentration of organic matter which, although sterilised, is not oxidised.

Twenty years ago The Lancet supported Dr. Alexander in introducing his electrolytic disinfectant. His latest report, which he hints is a swan song, is an earnest contribution to the solution of a complicated question, which nevertheless does not appear to be finally solved

## "THE BULLETIN OF HYGIENE."

It is estimated that about 25,000 scientific journals are now in circulation. To keep in touch with more than a few of them is beyond the powers of an ordinary man, and it is only justifiable to add to the number if the addition is designed to collate important information from many. This is a real service. It may confidently be expected that the *Bulletin of Hygiene*, issued by the London Bureau of Hygiene and Tropical Diseases (of which the first number has just appeared), will fulfil its promise and become recognised as one of those journals which have a useful function. The *Bulletin* resembles the *Medical Science Abstracts and Reviews*, which used to be published by the Medical Research Council, in that it is a collection of précis of papers published elsewhere. Its scope, however, is nothing like so wide. It deals primarily with hygiene rather than general medicine, and apart from the section on tropical diseases it is mainly restricted to publications written in English, though suitable papers and reprints in any language, if sent to the Bureau, will be noticed as far as possible. This limited field makes it possible to give more expansive notice to each paper than was possible in *Abstracts and Reviews*, and the resulting journal is rather more readable though less comprehensive and ambitious. It is to take the place of the old Sanitation Supplements, now discontinued. A representative list of contributors and commentators is given at the beginning and we forecast success for the new literary adventure. We hope that it will be an editorial policy to take more notice of foreign publications

## AN EIGHTEENTH CENTURY ESSAY ON GOUT.

William Cadogan was an eighteenth century physician who, like his mediæval predecessors and certain of his contemporaries and successors, such as William Kitchiner, John Paris, and Thomas King-Chambers, did not disdain to discuss the problems of diet, the iniquity of quackery, and the folly of polypharmacy. Though prominent during his life he has suffered "the iniquity of oblivion," and there are few to-day who could say much about him. From this neglect he has been rescued by Dr. Ruhräh, who in a charming little book[1] has republished the essay on Gout, and a friendly satirical poem or poetical version thereof by a Mrs. Ireland, together with an informing introduction giving details of Cadogan's life and work. He was born in 1711, entered at Oriel College, taking his B.A. in 1731, studied medicine on the Continent, and took his doctor's degree at Leyden in 1737. Returning to England he served for a short time in the army and then settled in Bristol, where he was living in 1752, when made a Fellow of the Royal Society. In 1754 we find him in London as physician to the Foundling Hospital. In 1755 he took the three degrees of M.A., B.M., and D.M. at Oxford, and in 1758 was elected to the College of Physicians, of which body he was four times censor and upon two occasions Harveian orator. He lived in George-street, Hanover-square. He wrote an essay upon Nursing and the Management of Children, as well as the better known essay on Gout. This essay on Gout, which was originally published at 1*s.* 6*d.*, is written in the scholarly and dignified English of the period and had a great vogue. It was evidently widely read and was the subject of much discussion, giving rise also to satirical "Enquiries" and the amusing poem by Mrs. Ireland referred to above. The book, first published in 1772, is a reasoned argument upon the uselessness of drugs for the cure of gout and upon the necessity of leading a rational life free from indolence, intemperance, or vexation, which calls to mind the lines in the "Regimen Salernitanum"—

---

[1] William Cadogan: His Essay on Gout. By John Ruhräh, M.D. New York: Paul B. Hoeber. 1925. Pp 114. $1.50.

> "Medici tibi fiant
> Haec tria, mens hilaris, requies, moderata diaeta."

Cadogan's remarks upon diet are sound enough, and his diatribes against quackery even more applicable to-day than when they were written. He was in advance of his times in his strong recommendation of massage (p. 90) and gentle exercise, the latter to be gradually increased. Dr. Ruhrah and his publisher are to be congratulated upon having given to the profession so charming a reprint of an excellent essay.

---

In view of the large number of inquiries received, the Ministry of Health desire to make it clear that persons engaged in excepted employment—e.g., railway clerks and certain local government employees earning not more than £250 a year—may be qualified to become voluntary contributors under the combined scheme of health insurance and Widows', Orphans', and Old Age Pensions, if they have been insured under the National Health Insurance scheme for at least two years at any time since July, 1912, or if they served in His Majesty's Forces for at least two years during the late war. Any such persons who desire to avail themselves of this right should get into touch with an approved society, or if they do not wish to join a society, with the Ministry of Health. As voluntary contributors they would be required to pay the full weekly contribution (normally 1*s.* 6*d.* for a man and 1*s.* 1*d.* for a woman), but where pensions contributions are also paid in respect of their employment, suitable arrangements will be made to refund any contributions paid in duplicate.

---

Public Health Course for Nurses.—The public health section of the College of Nursing has organised a course of study and lectures, lasting from April 1st to 15th, to assist nurses of the public health staff in their professional education. The courses held in the two weeks may be taken separately if desired, and, for both or either, grants may be given by the local authorities (under the Maternity and Child Welfare Act with the approval of the Ministry of Health) to cover the expenses of the nurses. The study and coaching week has been arranged during the Easter holidays to make it easier for nurses to attend, and this week starts on April 1st. The post-graduate week lasts from April 8th to 15th. The study week will be under the charge of a tutor and will include classes in anatomy, physiology, and hygiene, and lectures on sanitary law. During the post-graduate week there will be lectures on Poor-law reform, State insurance, cancer research, sunlight treatment, the maternal mortality-rate, diseases of early infancy, encephalitis lethargica, the wife under English law, and the lost heritage of childhood. Amongst the lecturers will be Sir Henry Gauvain, Mrs. Crofts, Sir John Robertson, and Mr. Cecil Chapman, and it is hoped that medical officers of health will assist by permitting as many of their nursing staff to attend as possible. The course will be held at the College of Nursing, Henrietta-street, Cavendish-square, W. 1.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLX.—TREATMENT OF MOVABLE KIDNEY.

The failure to appreciate that any abnormal or pathological condition found on examination is not necessarily responsible for symptoms has led to much loose thinking over the movable kidney. In the asthenic state the patient complains of weakness, of being easily tired, and of vague pains, especially in the abdomen; clinical signs are usually absent. As the most conspicuous feature is a want of nervous tone, the name neurasthenia, which literally means a *weakness of the nerves*, has been applied. Probably no word in medicine has been more misused, for it has come to denote anything from laziness to insanity. Unfortunately this condition is constantly confused with the psychoses and neuroses, which resemble it in so far as no clinical signs are found. In these, however, the symptoms depend not so much on a want of tone in the nervous system as on a perverted activity. Neurasthenia is frequently associated with visceroptosis; on the erroneous supposition that ptosis of the viscera is the cause of asthenia, treatment has been directed to the kidney, which is the most easily palpated of prolapsed organs. Attempts to suture it firmly into its normal position were at one time common practice The fallacy of suturing the kidney or its capsule to the lower ribs, an operation at one time popular, is obvious. During inspiration the ribs ascend and the diaphragm with the underlying viscera descends. When the kidney is sutured to the ribs it moves upwards during inspiration, and, as the liver moves downwards, the kidney is constantly contused. Fortunately for both the patient and the kidney the sutures usually give way. While visceroptosis is apparently on the increase and is responsible for much suffering, suture operations are being more and more rarely performed. To-day the fashion is to assume that because a movable kidney is found in healthy people and permanent improvement rarely followed suturing it in place, it never can give rise to trouble. The symptoms are attributed to auto-suggestion and the patient is sent to the psychologist. While the suffering in the mass is probably less than in the days of the big operation, much unnecessary suffering does still occur.

The normal position of the viscera in the living is difficult to ascertain, since evidence from the post-mortem and dissecting-rooms, from abdominal operations, and from palpation during a clinical examination are, for various reasons, unreliable. The outline of the stomach and intestine and the pelvis of the kidney can, however, be shown up by substances opaque to the X rays such as barium and sodium iodide, and by this means definite information as to the anatomy of the living can be gained. It is found that not only does the position of the viscera vary with the posture adopted, but that in scarcely any two individuals is it the same. When a standard is taken as that to which the majority of people conform, extreme variations may exist with perfect health and no symptoms. We may conclude that an abnormally placed or mobile organ gives rise to symptoms only if its own function is affected or if it interferes with that of some neighbouring organ. It is only when other causes have been excluded, and when disordered function is attributed to the displacement, that treatment should be directed to it. At the same time, it must be remembered that such an organ is heir to all the diseases that may affect the normally placed.

### *Relation of the Movable Kidney to Nervous Disorders.*

When symptoms of neurasthenia are associated with a movable kidney no permanent improvement follows operation. In both neurasthenia and visceroptosis there is a want of muscle tone. It is probable that when they coexist, as so often happens, both are dependent on the same cause. Therefore, little improvement is to be expected from fixing the kidney, apart from that due to the enforced rest in bed, feeding, and suggestion. The constant traction upon the sympathetic system is supposed to lead to a feeling of tiredness at the end of the day and eventually to neurasthenia It is difficult to understand how this could account for the general want of tone. Fortunately, a device such as the Curtis belt, which by supporting the lower part of the abdomen exerts pressure in the direction of the normal pull of the muscles, will relieve any traction from the prolapsed viscera, particularly when combined with a period of rest in bed and a suitable diet. Belts designed to exert pressure upon the lower pole of the kidney below the costal margin are not recommended. Palpation of this region, with the patient standing, shows that considerable pressure would be required to have any action, and would interfere with the function of neighbouring organs such as the colon. Moreover, the pressure from such a belt is opposed to that normally exerted by the upper abdominal muscles.

A patient who accidentally finds a lump in the abdomen, or has been told that a kidney is movable, may attribute symptoms to this cause. Such symptoms bear no definite relationship to disordered function of the kidney There is in these cases not only a want of tone of the nervous system, but also marked instability Experience has shown that operation upon the kidney rarely leads to a cure, for pain is complained of in the scar, or the symptoms that persist are referred to some other organ Operation is definitely contra indicated in these cases, which are more suitable for the psychologist, and may yield to psychotherapy combined with the treatment usually prescribed for asthenia.

### *Indications for Operation.*

It has been suggested that when the symptoms disappear with rest and return on standing fixation of the kidney is indicated. This, however, is found in both neurasthenia and visceroptosis. It is only when the mobility interferes with the function of the kidney or that of the neighbouring organs—and this condition may, of course, coexist with general visceroptosis and neurasthenia—that operation is called for. The indications for operation may be divided into three classes.—

1. Where a movable kidney on the right side causes traction on the duodenum. This is rarely seen. When present it gives rise to attacks of vomiting that are always relieved by lying down, and must not be confused with the gastric symptoms due to visceroptosis Vomiting due to other causes must be definitely excluded.

2. When the mobility leads to attacks of pain resembling renal colic and known as Dietl's crises. Here operation is indicated, not only because the attacks will certainly recur, but also because pathological changes in the kidney may be developing Pain during an attack may be relieved by draining the pelvis of the kidney by means of the ureteral catheter. Such attacks are probably due, not to torsion of the renal pedicle, but to acute kinking of the ureter, for they can be immediately relieved by the passage of a ureteral catheter and reproduced by distension of the pelvis

3 When some obstruction of the ureter interferes with the normal peristalsis of the ureteral muscle the flow of urine is impeded. Dilatation of the renal pelvis with the formation of a hydronephrosis results, and gives rise to pain that is renal in its distribution. It is generally referred to the angle between the last rib and the erector spinæ in the lumbar region, less commonly to a point below the tip of the ninth costal cartilage or to the iliac fossa; occasionally it radiates into the groin or genital region (see diagram). It may or may not be aggravated by exercise, but is generally relieved by lying down Pain in these regions may be due to disease of other organs. That due to a hydronephrosis results from distension of the pelvis, and the great test is that pain of a similar nature and referred to the same place can be produced by injecting fluid up the ureteral catheter. Unless the pain can be thus reproduced, one should be most guarded in attributing it to a movable kidney. In many cases more urine than is normal can be drawn off from the ureteral catheter, and more can be injected before causing pain. If the injected fluid is a 12 per cent. solution of sodium iodide, the skiagram may show some dilatation of the renal pelvis. The amount that the normal pelvis holds is very variable (from 5 to 20 c.cm.) and dilatation means that pathological changes have taken place, and as our aim should be to apply treatment before this has happened, the first sign is that a pain similar to that complained of can be produced by distending the pelvis.

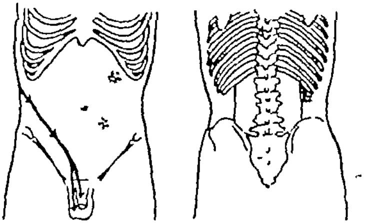

Diagram showing the regions where renal pain is felt.

*Hæmaturia* is sometimes seen apart from Dietl's crises When the common diseases that give rise to it have been excluded, it suggests that dilatation of the pelvis is taking place and is an indication for operation

### *Technique of the Operation.*

The lumbar incision should be sufficiently long to allow the pelvis and the upper end of the ureter to be examined. The kidney should be approached as if it were one giving rise to pain that is difficult to explain. Such conditions as a pure uric acid stone or a papilloma of the renal pelvis, which often escape our present methods of investigation, should be borne in mind. If there is any doubt, the pelvis should be opened and explored and a probe passed into the calyces. Aberrant renal arteries are often found and should be divided. Probably a more constant cause of disordered function are certain fibrous bands found compressing the ureter. They probably correspond to the fibrous bands which pass between the capsule of the kidney and the perirenal fascia. If present, they should always be divided. The perirenal fat is then removed, and the capsule of the kidney is reflected outwards and attached with strong catgut to the quadratus lumborum The sutures should not penetrate the cortex of the kidney If the neighbouring viscera are lying very low the kidney should not be fixed in the normal position, as its pedicle is likely to be compressed The patient should be kept lying down for at least three weeks; it is unnecessary to have the foot of the bed raised. A Curtis belt should have been ordered before the operation and should be worn in bed after the stitches have been removed, since its pressure may give rise to some discomfort at first. If the skin is treated with spirit and talc and the belt worn for a longer time each day, the discomfort should have disappeared by the time the patient is allowed up Active exercise should only be gradually resumed. The view that the presence of the movable kidney must be concealed from the patient dates from the time when the pathology of the condition was by no means clear and must not be allowed to interfere with proper investigation of symptoms] on lines indicated above.

Of the movable kidneys that are discovered during routine examinations, probably less than 2 per cent. will require operation and the greatest care should be taken in their selection.

## THE DOCTOR'S CAR.

(From our Motoring Correspondent.)

### *How to Adjust Four-Wheel Brakes.*

Braking on all wheels is ideal when the system is properly adjusted; otherwise it is highly dangerous. Although it is almost universal practice to set the rear brakes to touch first, there is a lot to be said for allowing the lead to the front pair, for contrary to what might be supposed the back of the car is much more inclined to stay behind the driver when the front wheels are braked, especially on a down-grade. If the front wheels lock, however, the steering is completely useless; but this should never happen to a careful driver, who will use his hand-brake instead of applying the last ounce of force on the pedal. Many authorities prefer to use the pedal chiefly for the front wheels and rely on the hand-brake to apply the last ounce of force on the rear.

The most important point is that each pair should go on absolutely together, and the following is the best way of ensuring this. We will assume that the rear brakes are to have the lead. A sits in the driving seat and B slacks the thumb-nuts of the front brakes well off. He then sets up the back brakes so that they just touch when the pedal is not pressed, and the best way of discovering the exact point at which the shoe touches is to tap the drum with a pocket-knife and note when the metallic ring is deadened. B then slacks the nuts back two turns each and, holding a knife or small tool in each hand to tap the drums, commands A to press the pedal very slowly. B, keeping up a continuous tapping on the drums, can then hear if one brake comes on before the other and adjust accordingly. When the back brakes are synchronised he goes to the front and gets A to put on a light pressure, as he would if he wished to slow down for a block some distance away with plenty of time in hand. B then tightens the nuts till the ring is deadened and tests with A for synchronisation, just as he did at the back. This will give a good, efficient setting. It is vital to keep four-wheel brakes properly adjusted, as to drive on a greasy day with one front brake going on long before the rest is to ask for serious trouble. Incidentally, the introduction of four-wheel braking forces makers to fit much more convenient adjusting nuts than they ever used to supply for a single pair of brakes.

### *Car Prices in 1926.*

Now that the market is at a low ebb for both new and second-hand cars, many practitioners will be considering purchase. They would be well advised not to delay, as the spring always produces a large crop of orders and the more popular makers develop a long waiting-list. Moreover, the price of second-hand cars goes up with a rush. The *Motor* recently issued as a supplement a booklet which gives the price, engine dimensions, tax, and particulars of the gears and brakes of nearly every car on the English market, with the maker's address. Medical men who are thinking of buying a car should expend 6*d.* on a copy. Except for the Ford 2-seater at £120, the cheapest car remains the Trojan, all models of which are fitted with pneumatic tyres for £5 extra. The pneumatic-tyred touring model is £130 and the saloon £158. Next comes the Austin 7 at £149 and the Jowett 7 at £150, with the saloon at £200 on a longer chassis. The Jowett has slightly the larger engine, and pulls its saloon with surprising ease, but the baby Austin is extremely fast and lively and is conspicuous for its leg-room; its "boot" will hold a great deal of luggage. It has four-wheel brakes, but the front and the back wheels are braked independently. Then there is the small Peugeot 7 at £155, or £165 with the cabriolet body. This is the smallest car in the list, having a capacity of only 719 c.c., but develops amazing power for its size. The Morris-Cowley 2-seater is wonderful value at £162 10*s.* without and £170 with f.w.b. The fixed head coupé at £195 will appeal to many practitioners. This car has very sweet controls and an exceptionally silent and trustworthy starter. Clyno make an 11 and a 13. The right-hand control and the large front-wheel brakes are good features. Two qualities of bodywork are fitted to the 11; the Standard 2-seater with f.w.b. costs £170 and the Royal £210. The 13 2-seater costs £245 and the coupé £285. The Chevrolet 20 is another example of the cheap American school at £165 for the 5-seater. The Rover 9 superseded the well-known air-cooled 8, and has a very efficient overhead-valve engine; the 2-seater costs £185, and another old-established firm (Lea-Francis) make a 10 and a 12 at £210 and £275 with four-wheel brakes (f.w.b.) for the 2-seater. The Gwynne 8 with its lively little engine costs £225. From this price upwards there are an embarrassing number of sound propositions. The Morris-Oxford has the virtues of the Cowley combined with a larger engine and more luxury. The 2-seater costs only £240, and the covered models £295 (three-quarter coupé) and £330 (cabriolet). A.C.'s have a new Sovereign model at £250. The Wolseley 11–22, with f.w.b. optional, is popular with the practitioner, since it has a certain air of dignity as well as being a first-class motor-car. The two 2-seater models cost £235 and £265, and the light saloon £295. The Essex 6-cylinder coach has come down to £280. The Hillman 14 touring car at £295 is a fine example of medium-powered English practice, and another model new this year is the Standard 12, which with the all-weather touring body costs £275. For those who can afford up to £400 there are the Armstrong-Siddeley 14 at £330 for the 2-seater with f.w.b.; the Hampton 12 coupé at £345 with f.w.b.; the Phœnix 11·9 all-weather at £365; the Riley 12 saloon with f.w.b. at £395; and 6-cylinder Overland 22 saloons at £340 and £375, with f.w.b. Studebakers' make three 6-cylinder cars rated at 27, 29, and 35. The 27 2–3-seater touring saloon is good American value at £390. All these cars have hydraulic f.w.b. It is extraordinary how few cars are priced between £400 and £500. This seems to be the gap between two distinct markets. The Cluley 14–30 saloon (f.w.b.) at £475 and the Crossley 14 coach (f.w.b.) at £455 do their best to fill it; the Calthorpe 6-cylinder 15–45 (f.w.b.) also comes in this interval with £425 for the touring model, which is very good value. Over £500, however, the range of choice is almost infinite. The Humber 12–25 coupé or saloon at £555 is a splendid and reliable car; Vauxhalls' make two open 14–40 models with f.w.b. at £550; the Canadian Buick 20–58 overhead valve 6-cylinder with f.w.b. and 4-door saloon costs £550. The Talbot 12–30 6-cylinder coupé at £555 and the Rover 14–45 coupé with f.w.b. at £660 are first-class English cars.

For the few who look higher there is the Aston-Martin 11·9 coupé at £825. The touring model costs £725. This is in a different class from all other small cars. The chassis is made up entirely by hand, and the parts are mated by craftsmen; when it is completely assembled it is run in thoroughly, and the owner can then do what he likes with it, without any attention but ordinary greasing and cleaning. Daimlers' have six distinct 6-cylinder chassis to choose from, varying from 16 to 45 h.p. with a wide choice of bodywork for each. All have the silent Knight engine. The 16 saloon "Y" costs £715; this has three speeds; all the others have four. The 30 enclosed laudaulet costs £1900, and the type N 45 costs £2250. Bentleys' make a very fine 15·9 light tourer at £995 and a standard coupé at £1350; and the Rolls-Royce 20 6-cylinder chassis at £1100, with f.w.b. £85 more, is now well known. Lanchester 21 6-cylinder short chassis at £1000 and long chassis at £1050; the Ford-Lincoln 8-cylinder 5-seater coupé at £1350; the Hispano-Suiza chassis at £1650; the Isotta-Fraschini chassis at £1550; and the big Rolls long chassis at £1000 are other examples of the most expensive class. The largest engine on the market is that of the Renault 45 6-cylinder, the capacity of which is 9 litres. The long chassis costs £1050.

### *On Gloves.*

Not many doctors clean their own cars except in an emergency, but if this should arise a pair of waterproof gloves are invaluable. The "Cozee" washing-glove (H. Baily and Co, Ltd., Glastonbury, Somerset) is made of best English sheep-skin, chrome-tanned by a special process, and is impervious to water. The thick soft fleece will hold water but no grit, is very soft on paint-work but effectually loosens the dirt. Inside the glove is a convenient grip-bar, with slots for the fingers, and a cow-hide cuff protects the user's wrist, around which it tightens with a strap and a rustless buckle. The dimensions of the glove are about 11 in. and 9 in., and its price is 8*s*. 6*d*. Dry, it makes an excellent polisher. If such gloves are not available, rubber gloves of which the wrists can be tied over a mackintosh, can be obtained at 6*d*. each at Woolworth's. Before starting operations involving the use of grease or oil, without gloves, both hands should be rubbed over with nearly dry soap and the nails filled up. Should this precaution have been omitted, Gresolvent is useful for cleaning hands. On the subject of gloves, every motorist who drives at night, especially in suburbs where traffic is thick, lives in fear that overtaking cars may not see his signalling hand. A loose white gauntlet without fingers, such as any needlewoman can make in 20 minutes, slipped over a driving glove is conspicuous even in a dim light.

### *Pictorial Road Plans.*

The third of the series of pictorial road plans, published at 6*d*. each for the Dunlop Rubber Co. by E. J. Burrows and Co, 43, Kingsway, London, has reached us. It describes the Bath road and the alternative roads from London to Milford Haven, via Brecon and via Cardiff and Swansea. The little pictures of places and things to be seen on the road will enhance the pleasure of the run. Milestones are clearly marked and the height of the road above sea level indicated at various points. Clear large scale maps of every important town crossed are given. The only suggestions we would offer concern these. Experienced motorists passing through Reading towards Bath do not follow the road outlined, but take the more direct route through Berkeley-avenue, avoiding much traffic and rejoining the main road just before it crosses the Great Western Railway. The town of Bristol presents exceptional difficulties to the stranger, who will welcome the help here given; the indication of the position of the "tramway centre," to which he is sure to be referred by friendly townsmen or the local police, would put him in a position to make intelligent use of their advice.

## MEDICINE AND THE LAW.

### POINTS FROM RECENT INQUESTS.

THOUGH the Home Office has not made conspicuous progress of late with legislative proposals in which it is interested, there is hope that Parliament may shortly pass the Government Bill for amending the law relating to coroners. If so, the whole subject will doubtless be dealt with thereafter by a consolidating statute. Meanwhile inquests continue to disclose points worth considering when the amendment of the existing law is undertaken. At the Wiltshire Assizes a fortnight ago John Lincoln was charged with the murder of Edward Charles Richards. An inquest had been opened on the death of Richards, but the coroner (Mr. A. L. Forrester) had exercised a wise discretion in confining the inquiry to evidence as to the nature of the dead man's wounds, the question of criminal responsibility having been taken up by the magistrates. While the inquest stood adjourned, the trial at the assizes proceeded and resulted in the conviction of Lincoln as the murderer. There was thus no further need for the coroner to investigate the cause of Richards's death, and the jury were brought together again to record a formal verdict. As the evidence at the inquest had been confined to the wounds only, the coroner suggested that the verdict should be that the deceased was shot by a person not identified and against whom no evidence had been offered in that court. The coroner's jury evidently stood upon its dignity. One juryman is reported by the *Times* to have objected strongly to a jury being asked to agree against its own convictions. Eventually, after a long absence, the suggested verdict was returned, but the foreman announced that the jury decided to add a rider, and, when the coroner refused to accept any rider, said: "We are of opinion that there has been a grave miscarriage of justice."

Provision is made in the Coroners Bill for avoiding the simultaneous conduct of proceedings before magistrates and coroner in such a case, but it is interesting to note that coroners' juries may resent the usurpation of their time-honoured functions. Where the cause of death is conclusively established by a conviction for murder, it might be better to let that fact operate as the termination of an adjourned inquest.

Another matter for consideration in any amendment of the law is the question of the place where inquests are to be held when death is the result of a motor accident. At present an inquest is held at the place where the body lies. The proper place, suggests Mr. C. W. W. Surridge, the Manchester city coroner, is the place where the accident occurs, where the coroner and jury (if a jury is required) can contribute and employ the knowledge they possess of the locality. "The barrier," said Mr. Surridge, "which prevents this common-sense procedure is that the law enforces the viewing of the body by the coroner; I deeply regret that the draft of the new Coroners Bill perpetuates this useless anachronism." Here, as in the Trowbridge inquest, one detects the survival of the ancient function of the jury, which was to declare the facts they knew rather than to listen to evidence of which they may be supposed ignorant.

Nothing seems to be attempted by the Bill in the direction of another quite different matter—the holding of inquests by coroners into outbreaks of fire. There has been some official backing for this proposal, and it has been strongly advocated by Dr. F. J. Waldo, who, as coroner for the City of London, has unique jurisdiction of this nature. There are frequently occasions where arson is suspected and where judicial investigation would be valuable, though it may be that the coroner is not necessarily the best tribunal for the purpose. Yet another question of the coroner's functions is raised by a recent incident at Leigh. There was something of a scene at an inquest, one herbalist after another being removed protesting from the coroner's court. A correspondent of the *Manchester Guardian* asks under which section of the Coroners Acts a coroner can consider himself authorised to hold an inquest where people are attended by an unregistered medical practitioner. He suggests that, if a coroner acts for any other purpose than to inquire into the death of a person within the provisions of Section 3 of the Act of 1887, he exceeds his powers and justifies a protest. Each case depends, of course, upon its own set of facts, and there is the high authority of Mr. Justice Stephen for the principle that the coroner cannot hold inquests as a mere matter of caprice. "It would be intolerable," observed that judge, "if he had power to intrude without adequate cause upon the privacy of a family in distress, and to interfere with their arrangements for a funeral. Nothing can justify such interference except a reasonable suspicion that there may have been something peculiar in the death—that it may have been due to other causes than common illness." Without denying the truth of these dicta, it may be added that the coroner's discretion is not likely to be interfered with lightly.

If he does not hold an inquest when he should, the courts will direct him to investigate. If he holds an inquest when he need not, there is only the indirect remedy of addressing the Lord Chancellor for his removal. As to the particular case under discussion, it is perhaps sufficient to say that if coroners are expected and entitled to investigate allegations of negligent treatment by practitioners, the qualifications and methods of the person administering treatment are circumstances of material significance.

### REGISTRATION OF OPTICAL PRACTITIONERS: A NEW BILL.

The draft of a Bill to secure "the registration of optical practitioners and to regulate the practice of sight-testing and optical dispensing and for purposes incidental thereto," has been issued by the Joint Council of Qualified Opticians. The Bill is largely modelled upon the Acts which govern the profession of dentistry and is an ambitious proposal to standardise two new professional types, optometrists and dispensing opticians, and to set up a central optical board, a register, and a monopoly of practice. We find in the Bill no defined or assured standards of teaching, training, examination, or conduct. This would seem inevitable, since the standards and the system of education for the new profession, to which the Bill proposes to grant privilege and protection, do not yet exist; nor is there any college or other institution which can suitably furnish them. It is unlikely that Parliament would consent to grant a vocational monopoly in these circumstances, and ophthalmologists who feel strongly that such innovations would be against the public interest need not, we think, be disturbed by the introduction of this Bill.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

### *Suicides in Vienna.*

IN the year 1925 the number of persons who committed suicide was 2259, of whom 53 per cent. were males. In 1914 the figure was 1286. It fell during the war to reach 700 in 1917, but since then there has been a fairly steady rise. For the first four years after the war the number stood at about 1200 (though it fell to 923 in 1922), but in 1923 it rose to 1458, in 1924 it was 1870, and last year it jumped up again to the huge total mentioned. During the same period the population has been steadily falling—in 1914 it was 2,120,000, in 1920 1,806,000, and in 1924 1,801,000—and the inference is that economic and psychical conditions in this city are far from satisfactory. The most usual means of suicide is by poison.

### *Lawyers and Abortion.*

At a mass meeting of the practitioners of the ninth Vienna district at which the problem of the interruption of pregnancy was discussed, an important statement was made by Dr. Altmann, President of the Court of Justice, who pointed out that the attitude of the courts at the time of passing the law (1759, 1802, 1841) was that of strict condemnation of abortion except when the life of the mother was in actual danger. Even then it was not very easily accepted. Up till quite recently the standpoint of the courts hardly changed at all, and except during the few years of the war, when vigilance relaxed somewhat, the same conditions prevailed. Two years ago, in fact, a renewed warning to the profession was issued by the Supreme Court. This met with indignant repudiation from many quarters, especially from eugenists. The new Act dealing with this subject, which is in preparation, recognises the necessity of taking into consideration not only danger to life, but also danger to health as being possible indications for abortion. Prof. Tandler, head of the Municipal Board of Health and Charities, strongly advocated in the discussion the necessity of recognising the social or economic factor as an indication for medical abortion. He is in favour of handing over the decision in each case to a committee of three, consisting of a physician, a public officer of law or administration, and a mother. This body would have to consider the case individually, and if it agreed on the advisability the operation would be allowed. The increase of population by the offspring of the mentally defective, the syphilitic, and the morally insane ought, he considers, to be prevented if possible.

## UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

### *The Prevalence of Cancer.*

ALTHOUGH it is generally believed that cancer is rapidly increasing, a statistical study just published in New York does not support this view. The statistical bureau of the New York Metropolitan Life Insurance Company has issued a report on an analysis of deaths from cancer amongst its industrial policyholders covering a period of some 14 years which deals with 90,175 cases. Dr. Louis L. Dublin and his assistants, who are the authors of the report, are distinctly reassuring about the situation, and conclude that the increase in cancer has been small—much smaller than might be inferred from an analysis of the published crude death-rate. Such as it is, the increase has been confined almost entirely to males, though the death-rate from cancer has always been higher amongst females. The increase has been largely in the later age-groups in each sex, perhaps because the average span of life has increased during the past 30 or 40 years. The white race is more prone to cancer than the coloured, and some nationalities of the white race are more susceptible than others. According to the annual report of Dr. A. Lessard, Director of the Bureau of Hygiene of the Province of Quebec, the citizens of English nationality appear to be more susceptible to cancer than their French Canadian neighbours, and the report of the Metropolitan Life Insurance Company states that the Russian immigrants seem most susceptible, that the Irish come next, and that the English, Scotch, and Welsh are affected in that order. The Italians are remarkably free from malignant disease, and the question naturally arises what light this throws on the influence of diet.

### *Pan-American Red Cross Conference.*

Seventeen nations have been invited by President Coolidge to attend the second Pan-American Red Cross Conference to be held in Washington from May 25th to June 5th next, under the auspices of the League of Red Cross Societies. It is expected that arrangements will be made for concerted relief for the victims of earthquakes and other major disasters, and for the participation of the societies represented in schemes designed to raise the standard of health of the entire Western Hemisphere. The agenda of the conference includes such subjects as child welfare, prevention of infantile tuberculosis, school hygiene, organisation of summer colonies and school dispensaries, popular health instruction, and the combating of malaria, hookworm, and other diseases. Besides Canada and all the nations of South America which have been invited to the conference, the Oriental Leagues of Red Cross Societies are expected to send delegates, and each Society has been invited to bring representatives of the public health organisations of its Government. An announcement made recently indicates that the International Red Cross Committee in Geneva, the League of Nations, the Rockefeller Foundation, the International Council of Nurses, and many other organisations are likely to participate.

### *Brooklyn Medical Society to Admit Laymen.*

The King's County Medical Society of Brooklyn, a part of greater New York, has decided to break a precedent by allowing laymen to become associate members. They will be permitted to attend and take part in all the regular meetings and discussions of the organisation, but will have no voice in the administration. The parent medical society of the State of New York must, however, give its approval before the change becomes effective.

### *Women's Industrial Conference at Washington.*

At the Women's Industrial Conference at Washington, which opened on Jan. 19th, Dr. Alice Hamilton, of the Harvard Medical School, speaking on industrial hygiene, declared that the United States Public Health Service was starved; it lacked a sufficient budget to accomplish essential experimental and research work. She contended that there were new factors in industry which were extremely dangerous to the health of the workers, and that tests should be made continually to determine their effects. The Public Health Service should do this work, and the service ought to be enlarged so that it could undertake the task successfully.

### *Saratoga Spa.*

A scheme has been formulated for developing the New York State mineral spring reservation at Saratoga Springs into a great public watering-place, equipped after the fashion of the famous spas of Europe. The suggested expansion, which, it is said, will give the public the full benefit of New York State's valuable mineral water resources, is estimated at $9,000,000. For several years the money available for the development of the Saratoga reservation has barely sufficed to provide bathing accommodation for the people who visited the springs, and lack of funds has prevented the establishment of a regular water cure. The popularity of the treatment provided has, however, been steadily increasing.

# Public Health Services.

## NURSING AT THE SHIRLEY WARREN INFIRMARY.

A REPORT by the medical superintendent, Dr. E. L. White, reveals the unsatisfactory conditions under which nurses have been working at the Shirley Warren Infirmary, Southampton. During the last three and a half years eight nurses have contracted pulmonary tuberculosis and four of these have died, and the number warded in the sick-room has risen from 21 in the last six months of 1922 to 54 in the corresponding half of 1925. The illnesses, it appears, are more serious and last longer than formerly, and there has been at the same time a steadily increasing amount of disability not needing sick-room treatment. In Dr. White's opinion the sickness amongst the staff has been directly due to their hours of duty among the very heavy cases in the overcrowded wards. At this infirmary the total nursing staff (excluding the matron and her assistant) is 61, and the number of patients is 405. The nurse-patient ratio during the day is 1–10, and at night it is 1–34. The sister-patient ratio is 1–83 in the day and 1–250 at night. Junior probationers work 60 hours a week, staff nurses 62, and night nurses 65. The sisters have theoretically a 48-hour week; but in practice all these figures are a too low estimate, because neither nurses nor sisters can leave their wards at the appointed times on account of the high pressure of work, and meals are taken hurriedly out of proper hours.

No one can defend these conditions of duty, while Dr. White has pointed out that long hours do not form the only introduction to ill-health among the nursing staff. He says:—

> "The obligations laid upon the guardians by the General Nursing Council, as the determining authority for State registration of nurses, increase the strain thrown upon the probationers, who are constantly being prepared in classes and on the wards for the preliminary and final examinations of the Council. These examinations are held every three months and I am obliged to keep the nurses studying continuously for the examinations, because it is in the interest of the whole staff that as many out of each batch presenting themselves should pass the examiners; otherwise the number for preparation increases, the wards are depleted more and more as the candidates are drawn from them for their lectures or demonstrations, and the number of probationers who can be pushed on towards completion of their training diminishes, therefore preventing the senior posts rendered vacant by consecutive resignations of the certificated staff nurses being filled by competent probationers well abreast of their studies. Although I myself am on the Board of Examiners of the General Nursing Council, I do feel that the continual worry and anxiety caused to girls in the early months of their training, through contemplation of the enormous quantity of theoretical knowledge to be acquired before they can acquit themselves with credit at the examinations, is a determining and detrimental factor in our present difficulties. It is frequently happening that nurses leave, or very seriously think of doing so, because of this quite unnecessary spectre looming ahead of their careers; not only so, but I am of opinion that the more conscientious and hard-reading girl is rendered less capable physically by reason of the high pressure at which she must take her so-called off-duty time—too largely eaten into by stewing in class-room or bedroom over problems laid carefully by thoughtless cranks in the path of women totally unable, from a variety of causes, to deal even partially and superficially with them."

That the physical type of would-be probationers is not so satisfactory as it used to be is an unfortunate addition to the circumstances which reinforces Dr. White's recommendation of an increase of 11 in the staff. The guardians have, in fact, arranged for their appointment, and have resolved that suitable accommodation should be provided for them. But Dr. White's report raises important issues which must not be forgotten because the arrangements at Shirley Warren are likely to improve. It is deplorable that they should ever have existed, and the story is a sufficient reply to those who consider that a waning public spirit in the young is responsible for the decreased entry to the nursing profession. There is a growing demand for healthy conditions of life, and it is essential that there should never be any hint that nurses are exploited.

## *INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 30TH, 1926.*

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 365 (last week 369); scarlet fever, 2019 (last week 1818); diphtheria, 1210 (last week 1006); enteric fever, 33; pneumonia, 1351; puerperal fever, 74; cerebro-spinal fever, 8; acute poliomyelitis, 7; encephalitis lethargica, 66; dysentery, 4; ophthalmia neonatorum, 108. There were no cases of cholera, plague, or typhus notified during the week.

Of the 365 cases of small-pox, 43 (last week 26) were reported from the county of Derby, 30 of them from Derby C.B.; 182 (last week 175) from the county of Durham, 28 being from Gateshead C.B., 4 from South Shields C.B., and 1 from Sunderland C.B., the remainder being from widely scattered urban and rural districts and including 16 (last week 44) from Blaydon, 11 from Tanfield, 11 from Whickham, 26 from Chester-le-Street R.D., 14 from Easington R.D., and 18 from Sunderland R.D.; 51 (last week, 53) from the county of Northumberland, including 2 (last week 6) from Newcastle-on-Tyne, 12 from Ashington, and 28 from Morpeth R.D.; 13 (last week 8) from the county of Nottingham, including 10 from Sutton-in-Ashfield; 9 (last week 6) from the East Riding of Yorkshire, of which 8 were from Kingston-upon-Hull; and 68 (last week 62) from the West Riding, of which 60 (last week 70) occurred in Rawmarsh. No case was reported this week from the counties of Lincoln or Lancaster.

*Deaths.*—In the aggregate of great towns, including London, there were 5 deaths from enteric fever, none from small-pox, 102 (60) from measles, 13 (1) from scarlet fever, 53 (1) from whooping-cough, 33 (0) from diphtheria, 52 (11) from diarrhœa and enteritis under 2 years of age, and 100 (14) from influenza. The figures in parentheses are those for London itself. The mortality from influenza is again increasing, the figures for the last three weeks, working backwards, being, 100, 87, and 81.

"Audi alteram partem."

## CORONARY EMBOLISM.

*To the Editor of* THE LANCET.

SIR,—As attention has recently been drawn in THE LANCET by Dr. Charles H. Miller to the occurrence of embolism of the coronary arteries and by others to cases of coronary thrombosis it may be of interest to mention the following fatal case of coronary embolism.

A young coal-miner in apparently normal health went to his work as usual. Soon afterwards he was found lying dead in the pit without any sign of external injury. In order to ascertain the cause of the man's death the surgeon to the colliery performed an autopsy at which I was present at the request of the colliery owners. At first we failed to find any obvious explanation of the man's sudden death, but a closer scrutiny of the heart and aorta revealed the presence of the base of a single small vegetation, about the size of a pin's head, situated on the wall of the aorta close to the orifice of one of the coronary arteries. On opening up this coronary artery it was found to be plugged by a fresh embolus. This embolus had evidently become detached from the wall of the aorta and had been caught by the stream of blood entering the coronary artery and carried along until it was arrested at the point at which it was found. The sudden occlusion of this coronary artery and the consequent ischæmia of the heart wall supplied by it had evidently caused the sudden cardiac failure.

Prof. W. H. Welch states that the coronary artery is the rarest situation in which an embolus occurs. As a rule, emboli coming from the heart are swept past the opening of the coronary artery to be lodged elsewhere, so that in this case it was simply the position of the vegetation so near the origin of the coronary artery which determined the fatal course of the embolus.—I am, Sir, yours faithfully,

Manchester, Feb. 8th, 1926. GEORGE R. MURRAY.

## BONE-SETTING AND OSTEOPATHY.

*To the Editor of* THE LANCET.

SIR,—The enclosed letter was sent to the *Times*, but has not appeared. It has received the approval of certain of my colleagues and you may think that its publication would be useful in view of the public importance of the situation set out.

I am, Sir, yours faithfully,
A. S. BLUNDELL BANKART.

Harley-street, W., Feb. 8th, 1926.

[ENCLOSURE.]

*To the Editor of* THE TIMES.

SIR,—Some of us have known from the first the real motive underlying the agitation about "the case of Dr. Axham." But, until Sir Herbert Barker's letter appeared in your issue of Jan. 23rd, the public may not have realised that this is a political agitation on the part of (American) osteopaths, chiropractors, and others, for legal status in this country. The "more fundamental issue" is now, however, made clear, and it is well that the public should be informed of some of the facts.

Orthopædic surgeons are rather sorry that Sir Herbert Barker has identified himself with this movement, because his own reputation has been made in the practice of straightforward manipulative surgery, which is quite a different thing from osteopathy and chiropractic.

For very many years in this country that part of manipulative surgery which is practised by unqualified persons has been called "bone-setting." It is based upon the fact that many of the minor injuries that occur among healthy people at work or at play are followed by some limitation of the normal movement of a joint, due to some thickening and contraction in a ligament or muscle, or to adhesion between surfaces which should glide over one another, or to some detached portion of a cartilage getting in the way. Many of these conditions are promptly relieved by manipulation which breaks down or removes the obstruction and restores normal movement to the joint.

This kind of manipulative surgery has long been known and practised by orthopædic surgeons. But it is only in comparatively recent years that orthopædic surgery has been recognised in this country, and admittedly it has been neglected by the medical profession generally. Hence it comes about that individuals requiring manipulative treatment often seek relief in vain from surgeons who are well known or even famous in other branches of surgery, but who do not practise manipulative surgery.

The unqualified bone-setter is on fairly safe ground so long as he confines his attentions to the effects of minor injuries in healthy adults. But when he essays to manipulate stiff joints in children and some others, which require surgical knowledge and training for their correct diagnosis, he is asking for trouble, and he almost invariably gets it.

Osteopathy and chiropractic are quite different from manipulative surgery or bone-setting. They are typical Yankee money-making stunts. The osteopaths have invented an imaginary "lesion" of the spine. It is a displacement of the little joints so subtle that it cannot be detected by the X rays nor by anyone who has had the training of a surgeon. This displacement is alleged to narrow the space between two adjacent vertebræ of the spine, so that the nerves which come out between them are pressed upon. Lastly, this pressure is said to produce far-reaching effects upon the distant parts of the body supplied by those nerves. The treatment consists in correcting these imaginary displacements by repeated manipulations of the spine.

Some 30,000 persons—a large proportion of them uneducated and even illiterate—are practising this "art" in America and Canada. A few have obtained a better education and have taken medical degrees. It is noteworthy that as soon as an osteopath becomes medically qualified he has to discard the first principle of osteopathy—namely, pressure on the nerves by the displaced vertebræ, because it happens to be an anatomical impossibility. But that does not matter; he has invented another theory, equally imaginary, but a little more difficult to disprove—namely, that the effects are produced, not by pressure, but by "congestion" in the neighbourhood of the displaced vertebræ. There is, as a matter of fact, no evidence to show that such congestion occurs, or that, if it did, it would produce any of the effects that are conveniently attributed to it.

Osteopaths have sought to support their claims by "research work." The results of this work will be found in the *Bulletin* of the A. T. Still Research Institute, Nos. 1–5, published by F. Bischoff, 27, East Munro-street, Chicago. The impression left on one's mind after reading these volumes is that a few individuals with little, if any, scientific training, have got together with some large text-books of physiology and unlimited opportunities for performing the crudest experiments on animals, and have produced a mass of irrelevant facts, incredible observations, and wholly unwarranted deductions, beside which the more commonplace quack advertisement pales. It is not possible to find in them a single observation that any educated person would accept as of the slightest scientific value, and it is impossible to conceive what purpose this literature serves other than as propaganda to bolster up a preconceived and evidently false doctrine.

It should, however, be said that, just as a quack medicine sometimes contains a useful drug, so the manipulations of the osteopath sometimes do good. For, among their cases osteopaths number some of genuinely strained backs in which movements are restricted by adhesions about the joints or in the muscles, just as in other regions, and these can certainly be relieved by manipulations. But this is straightforward manipulative surgery or bone-setting, and not osteopathy. Moreover, a large proportion of these patients are known to be highly neurotic, and the manipulations of the osteopath for the time being produce a profound mental impression on them.

The chiropractor differs little from the osteopath, except that he does not extend his activities beyond manipulation of the spine, while in many cases at least the osteopath also does bone-setting.

Orthopædic surgeons appreciate much of the work of the genuine "bone-setter," and the public should not be misled into thinking that the essentially American osteopaths and chiropractors are of the same order.

I am, etc.,
(Signed) A. S. BLUNDELL BANKART.

London, W., Jan. 26th, 1926.

## THYROID GLAND AND CALCIUM THERAPY.

*To the Editor of* THE LANCET.

SIR,—Dr. H. W. Barber in his letter in your last issue invites opinions as to the value of calcium salts in the treatment of chilblains, and states that most of the patients who come to him have already taken calcium lactate over a long period without striking benefit. My own experience is that calcium salts are effectual in a large number of cases, but that there is a fairly extensive residuum of patients in whom they are valueless. The use of calcium as a possible remedy for chilblains is now so widely known throughout the profession that it is given in the majority of cases at the first interview between the patient and the doctor, and in many cases it acts like a charm. I would suggest that the patients in whom Dr. Barber finds it useless belong to the residuum who derive no benefit from calcium.

I agree with Dr. Barber in his conclusions as to the lack of value of parathyroid in dermatological practice. It is the fashion at the moment to ascribe to a disordered endocrine system the production of any disease whose causation is unknown, and this tendency is apt to blind us to more tangible possibilities.

I have often wondered whether the dietetic factor enters into the ætiology of chilblains to a greater extent than is recognised at present. During the latter part of the war chilblains appeared to be more prevalent than now, and I have known patients who found a remarkable improvement in their condition when they were able to discard the margarine of those lean years and resume butter as a regular article of diet. Could we but follow our patients in the daily routine of their lives we should be surprised, I believe, at their startling ignorance of the elementary laws of health and not least in the matter of what constitutes an adequate diet.

I am, Sir, yours faithfully,
JOHN ALEXANDER DRAKE.
Harley-street, W., Feb 8th, 1926.

*To the Editor of* THE LANCET.

SIR,—The interesting and suggestive letter in your last issue from Dr. Barber touches on so many points of importance that I venture to ask you once more for the courtesy of your columns.

Dr. Barber lays stress upon the type of individual who develops chilblains. He points out that the sufferers from *pernio* often show other signs of circulatory sluggishness, especially noticeable in their fat and "œdematous-looking" legs—unsightly members characterised by *keratosis pilaris*. My therapeutic experience in this type of patient leads me into general agreement with Dr. Barber's conclusions—namely, that they do not derive benefit from either parathyroid or calcium administration. I have regarded the sufferers in this class as owing their vascular torpor and obese tendency to an underlying pituitary deficiency. Their treatment on empirical lines with thyroid and pituitary substance has, in some instances, been followed by marked improvement, both subjectively and objectively.

Dr. Barber concludes his letter by a suggestion that the basic abnormality present in these patients may possibly be intestinal auto-intoxication; but he does not think that this is the only factor. It is an interesting fact that these cases occur nearly exclusively in girls during adolescence, at a time when considerable demands are made upon the triad—ovary, thyroid, pituitary. It is quite conceivable that the presence of toxins in the blood, in addition to the strain entailed by growth, may be sufficient to produce a very considerable disturbance in the endocrine hierarchy. Moreover, in more than one case of this kind which has come under my notice there have been very decided indications of definite pituitary lesions in other members of the family, which suggested that the familial stability of this gland may not be above suspicion. In patients who belong to other types it is worth while, in my judgment, to administer parathyroid and calcium, until it is obvious that these remedies are failing to improve the lesions.

Dr. Grove, in his letter, suggests that the major premise of my letter is incorrect, "namely, that chilblains are associated with calcium deficiency." In support of this he informs us that, from the examination of two cases "we have expressly stated that the cases of chilblains had normal blood calcium." He admits that "chilblains are very deceptive things to treat." I would like to go further and suggest to him that they are also very deceptive "things" upon which to dogmatise, especially where such a factor as calcium metabolism is concerned. Two cases seem a small allowance upon which to base a generalisation. Again, Dr. Grove writes: "I do not know who originally stated that chilblains had calcium deficiency." I regret that I am unable to inform him on this point, but he may be glad to be reminded that so long ago as 1896 Sir Almroth Wright showed that chloride of calcium notably increased the coagulability of the blood, and that this was in all probability the commencement from which calcium therapy in chilblains, erythema, and urticaria arose. It would be very instructive if the blood in a large number of patients suffering from chilblains could be examined under differing circumstances, and under various climatic conditions, and the calcium content determined.

Finally, I am glad to know that Dr. Grove finds injections of sodium cacodylate so certain a cure. No doubt the arsenic element assists the general nutrition of the skin.

I am, Sir, yours faithfully,
IVO GEIKIE COBB.
Queen Anne-street, W., Feb. 8th, 1926.

## THE TREATMENT OF TINNITUS AURIUM.

*To the Editor of* THE LANCET.

SIR,—I have been much interested in reading Mr. Mollison's article on this subject in your issue of Jan. 16th.

Briefly the classical method of treatment so well expounded there by Mr. Mollison falls under two heads. First in cases where there are objective signs it consists mainly in inflation of the Eustachian tubes with or without injection of vapours and the use of the bougie, and in cases without objective signs, whatever the cause of the deafness, and it is often quite unknown, treatment of the tinnitus runs on similar lines: "drugs and general advice with encouragement." I agree with Mr. Mollison that when carried out on these lines "the treatment of tinnitus is unfortunately often disappointing." We are not, however, compelled to confine ourselves to these classical methods. For instance, for some time I have been using a new method of treatment which has given me much better results than the classical methods of treatment.

In your issue of May 9th, 1925, I published a record of 100 patients with chronic progressive deafness. Sixty-eight per cent. of these patients, after all other methods had failed, were alleviated by treatment with the Zund-Burguet electrophonoide. Of these 100 patients 36 suffered from tinnitus and 26 of them—i.e., 72 per cent.—after the treatment found that the tinnitus had disappeared; that is to say, although the deafness had only been alleviated the tinnitus had been cured. At the present time I have two patients, one a girl aged 20 who has suffered from otosclerosis since the age of 10. She had tried every form of treatment for her deafness and tinnitus, and her parents, having been told that she would inevitably go stone deaf, have also had her taught lip-reading. Before treatment she could hear from 4 to 5 ft. on either side, after treatment she can now hear at a distance of 20 ft. on the left side and 25 ft. on the right side, and the tinnitus has disappeared. The other is an old lady of 81; she is not deaf but complains of terrible noises in the ears, of which the most annoying is a "railway whistle"; after a few treatments the railway whistle noise has disappeared, and I hope that the others will disappear also.

Apropos of the treatment with the electrophonoide I should like to say a word anent the annotation that appeared in your issue of Dec. 19th, 1925, on Massage in the Treatment of Middle-ear Deafness, as given in Vienna. I have been acquainted with this treatment for some time, and I cannot see that it compares in any way with the treatment by the electrophonoide; besides, it applies only to chronic otitis media, whereas the treatment by the electrophonoide does good also in many otherwise intractable cases of nerve deafness and otosclerosis, as I explained in my paper of May 9th. I am treating a patient at present aged 51, who has suffered from chronic otitis media for 25 years and has been given up as hopeless after having tried every kind of treatment at home and abroad including the massage treatment aforesaid. When he came to me he could hear at a distance of 3 ft. on the left side and 1 ft. on the right. After 12 treatments he can hear at a distance of 15 ft. on the left side and 5 ft. on the right; he says also that there is no comparison between the pleasantness of the two methods of treatment. I am, Sir, yours faithfully,

GEORGE C. CATHCART.

## MANIPULATIVE SURGERY.

*To the Editor of* THE LANCET.

SIR,—The article by the Registrar of the General Medical Council is very interesting to those who may not have studied the Medical Acts, but I am afraid it only intensifies the feeling which exists in the minds of many medical as well as laymen that, in the case of Dr. Axham, the Council was acting outside the legal powers conferred by those Acts. From the beginning to the end of the Act it is clear it was intended to protect the public from the action of a qualified medical man passing off an unqualified one as if he were a qualified substitute. In the case of Dr. Axham he was not a principal, and his work as an anæsthetist was distinct from the manipulative part which was performed by a well-known bone-setter, and there was no attempt to mislead the patient into believing Mr. Barker (as he then was) to be a qualified medical man.

From the first paragraph of the Act it is obvious that the continued existence of unqualified practitioners was contemplated. At the time when Sir Herbert Barker, following on the late Mr. Hutton, began the practice of his work, known as "bone-setting," but now dignified with the title of "manipulative surgery," the correct and *in fact only treatment* taught students for dealing with sprains was an application of plaster-of-Paris bandages, and in my own early days in the Army Medical Service each invaliding day found us discharging men from the army with stiff joints as the result of the then orthodox treatment by plaster-of-Paris cases. As the profession *certainly does* owe its present and more rational method of treating sprains to the efforts of the old-time bone-setter, would it not be more dignified if we admitted our indebtedness? We might, in the future, advise the public as widely as it can possibly be done (by those who do not themselves practise this form of treatment so as to avoid the risks which would attend such advertising by those who do) that there is no longer any necessity to run risks of unqualified practitioners. New entrants into the field of bone-setting must go through a long training and period of experience (not by any means devoid of risk to the patients) before they arrive at real skill.

I am, Sir, yours faithfully,

BRUCE BRUCE-PORTER.

Grosvenor-street, W., Feb. 8th, 1926.

## CHARING CROSS HOSPITAL INSTITUTE OF PATHOLOGY.

*To the Editor of* THE LANCET.

SIR,—I am still of opinion, in spite of the rather irrelevant considerations which have weighed with Dr. Piney, that it is undesirable for institutions which are subsidised for other purposes to compete with ordinary businesses in this way. May we expect, on the same principle, the establishment of laundry services at cut rates by the Maida Vale and Charing Cross Hospitals? The benefit to the public health, in their respective districts, would, in my opinion, be greater than will accrue from the pathological service offered. I am, Sir, yours faithfully,

*Queen-square, W.C., Feb. 6th, 1926.* J. A. MURRAY.

## CHOLERA IN RUSSIA: A SATISFACTORY POSITION.

*To the Editor of* THE LANCET.

SIR,—We are informed that there has been a statement in one of the British newspapers to the effect that cases of Asiatic cholera were registered in the U.S.S.R. in 1926. According to the official information received by me to-day from the Commissariat of Public Health, the latest two cholera cases were registered in Soviet Russia in July, 1925. Not one case has been registered in the Union in 1926.

I am, Sir, yours faithfully,

V. N. POLOVTSEV,

Representative of the Commissariat of Public Health and the Russian Red Cross, U.S.S.R.

Southampton-row, W.C., Feb. 5th, 1926.

## HYSTERICAL DISORDERS IN CHILDREN.

*To the Editor of* THE LANCET.

SIR,—Dr. Wyllie, in his paper on Hysteria in Children, refers in his remarks on sympathetic vasomotor instability to the absence of bleeding on pin-prick which may be associated with the coldness and cyanosis of a hysterically palsied limb. It happens often, but not always, that we may thread a sharp pin, without the loss of a drop of blood, through the skin of a part which as a result of hysteria is anæsthetic or palsied or both. It also often happens that the anæsthetic skin of organic disease—e.g., tabes dorsalis—may similarly be bloodlessly transfixed, the risk of anæsthesia by suggestion being guarded against. Bloodless transfixion of the skin has come to be associated with hysterical conditions, but it has seemed to me that when it can be performed in an area of skin which is analgesic it depends on the loss of cutaneous sensibility rather than on any special condition which is giving rise to the analgesia.

I am, Sir, yours faithfully.

Harley-street, W., Feb. 8th, 1926. HILDRED CARLILL.

## INTRA-URETHRAL NEGATIVE PRESSURE DURING COITUS.

*To the Editor of* THE LANCET.

SIR,—In a footnote to a letter of mine with this title which appeared in your issue of Jan. 23rd you state that "we need more material on which to base opinions as to the value of prophylaxis."

A mass of most convincing evidence as to the value of prophylaxis was laid before the Trevethin Committee by medical witnesses who had practical first-hand experience of its use on a large scale, while criticism of the value of prophylaxis was based on theory and confined to medical witnesses who honestly stated that they had no personal experience to record. Twenty-five authoritative medical witnesses endorsed the value of prophylaxis, based on practical experience in England, Scotland, Egypt, Mesopotamia, Russia, and in the navy. You, Sir, are doubtless aware that the Conference of the United States Public Health Services and State Venereal Disease Control Officers, held at Hot Springs, Arkansas, in December, 1924, passed a resolution to the effect that "Measures of immediate disinfection to those exposed to these diseases have been proved to be scientific and practicable."

I venture, therefore, to think that it is not so much "more material on which to base opinions" that is required as a wider publicity of the material that we already possess.

I am, Sir, yours faithfully,

H. WANSEY BAYLY.

Harley-street, W., Feb. 4th, 1926.

WREXHAM HOSPITAL.—A new hospital, of which the cost, including site and furnishings, amounts to £100,000, is now approaching completion at Wrexham. Several thousand pounds have been subscribed by miners and work-people in weekly payments.

# Obituary.

## WILLIAM BATESON, F.R.S., D.Sc.,

DIRECTOR, JOHN INNES HORTICULTURAL INSTITUTION.

WE regret to announce the death on Monday last at his residence, Merton Park, Surrey, of Prof. William Bateson, the biologist who, by his close and independent researches into the subject of heredity, established his claim as a representative scientific leader, opening up fields of research and speculation whose harvest is of the finest promise to medicine.

William Bateson was the son of the Rev. Dr. W. H. Bateson, who was for 20 years the Master of St. John's College, Cambridge. He was born at Whitby in 1861, was educated at Rugby and his father's college, graduated in the first class in the Natural Science Tripos in 1882, and was duly elected a Fellow of St. John's. At that time Francis Maitland Balfour, who had just published an illuminating treatise on embryology, was appointed to a special professorship of animal morphology founded at Cambridge, and under his influence Bateson's first work had a strictly embryological outlook. But it soon took a wider shape as he became absorbed in the study of the problems of evolution. The paths into which a mass of original and intensive study led him were at first sight revolutionary—revolutionary, that is, in the eyes of those who thought that the work of Charles Darwin was finite. If that great man had been alive he would have been the first to dissociate himself from any idea that conclusions which he had arrived at were to be regarded as an unchangeable gospel, and although Bateson's studies of the phenomena of variation were regarded askance by pious Darwinians, it became clear, when his first text-book was published, that he was enunciating doctrines of fundamental importance in bringing forward arguments to show that nature was not condemned to progress only through the manifestation of imperceptible changes and acting through infinite periods of time. Bateson's brilliant "Materials for the Study of Variation" was published in 1894, and his work, with the theories which underlay it, received singular confirmation a few years later, when Mendel's three remarkable essays on heredity came to light.

So far had Bateson proceeded on similar lines that the doctrines of Mendelism were immediately clear to him, and when in 1902 he published his book, entitled "Mendel's Principles of Heredity," he was proving, though he never took up an egotistic position, that his own work was elevating the study of heredity into an organised branch of physiological science. And thus he steadily pursued his objects, and when in 1908 he was appointed professor of biology in the University of Cambridge he made the beautiful garden round his house in Grantchester a centre of intensive work for the establishment of principles which received largely the label of Mendelism though much might well have been categorised under his own name. At Grantchester a group of enthusiastic students under Bateson's direction, carried on researches into the phenomena of heredity of a valuable and practical description, while it was an amusing experience for those who went to consult Bateson in his open-air laboratory to inspect chicken-runs whose denizens were illustrating phases of nurture or motion, flowers displaying artificially produced qualities of shape or colour, and fruit bushes carefully netted and handed over to the depredations of caterpillars. A large quantity of these experiments were reported upon to an evolution committee of the Royal Society by Bateson and his assistant, Miss E. R. Saunders, and a memoir of exceptional interest was shortly afterwards published in which the hereditary variations of animals and plants, continuous and discontinuous, were recorded, as well as the specific effect that in-breeding might have in modifying the power of transmitting parental characters.

His tenure of the chair at Cambridge was brief, for in 1909 he resigned his professorship on appointment as Director of the John Innes Horticultural Institution, and Merton Park now became the scene of his continuous researches. He himself recorded in the Huxley Memorial Lecture, delivered at Birmingham, the exact position in which Darwin, Huxley, Mendel, and incidentally himself, stood in the developments of the fundamental theories of evolution. Though ever an enthusiastic advocate of Darwin's views, he showed that Huxley had always retained an article of faith excluded from the strict Darwinian creed, for to Huxley it had appeared that the importance of specific and discontinuous variation—labelled by this time the mutation theory—was of greater importance than Darwin's researches had prepared him to admit. Mendel's work pointed the way, said Bateson, to the essential fact that the forms and qualities of living things can in numberless examples be proved to depend on the presence of definite elements or factors distributed among the germ cells according to predicable systems, and the illustrations of this theory by a variety of phenomena in plants, animals, and man was the immediate work which lay under Bateson's hand. He dealt with all aspects of the subject in his work "Problems of Genetics," published in 1913, and in many communications on biological subjects; and while holding the general conclusion that with the progress of the later methods of analysis biology was passing into a new phase, he uttered warnings against the too ready acceptance of any violent generalisations.

The sum of well-deserved honours which accrued to Bateson was a large one. He was twice a medallist of the Royal Society; he was a corresponding member of scientific academies and societies all over the world; he was for two years Fullerian Professor of Physiology at the Royal Institution; he received many honorary degrees; and in 1914 he was President of the British Association at its session in Melbourne, when he took the occasion to review the discoveries made by the analytical methods of biological study in a masterly manner. The amount of personal work which had to fall under reference in telling the story[1] shows in itself the debt which science owes to Bateson.

Prof. Bateson married in 1896 Beatrice, daughter of the late Arthur Durham, senior surgeon to Guy's Hospital. She and one son survive him, two elder sons having died, one after injuries received in the war.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

THE following appointments have been notified: Surg.-Comdrs. R. H. McGiffin to the *President*, addl., for duty in Medical Department of the Admiralty, and H. R. B. Hull to the *Queen Elizabeth*, addl., for specialist duties in the Mediterranean Fleet; Surg. Lt.-Comdrs. H. Wilks to the *Pembroke* for R.N. Barracks, temp., and F. H. Voy to the *Lucia*; Surg.-Lts. G. G. Newman to the *Ajax*, H. W. Strong to the *Iroquois*, W. McCoach to the *Pembroke* for R.M. Infirmary, Eastney, T. Madill to the *Bee*, D. Glass to the *Keppel*, and W. P. E. McIntyre to the *Wallflower*.

Surg.-Comdr. G. T. Verry is placed on the Retd. List at his own request.

### ROYAL NAVAL VOLUNTEER RESERVE.

Surg.-Capt. W. E. Harker is placed on Retd. List.

## ROYAL ARMY MEDICAL CORPS.

Maj. T. W. O. Sexton retires on retd. pay.

### ARMY DENTAL CORPS.

Capt. E. R. Saul retires, receiving a gratuity.

Temp. Capts. T. Pearson and J. L. Craig, from Genl. List, to be Capts.

### TERRITORIAL ARMY.

Capt. N. St. J. G. D. Buxton (Maj., Res. of Off.) resigns his commn. in the T.A.

G. Tudhope (late Surg. Sub-Lt., R.N.V.R.) to be Lt.

J. Kerr (late Officer Cadet, St. Andrew's University Contgt., Sen. Div., O.T.C.) to be Lt.

### TERRITORIAL DECORATION.

The Territorial Decoration has been [illegible] upon Lt.-Col. W. Archibald and Maj. O. Te [illegible]

---

[1] THE LANCET, August 15th.

## ROYAL AIR FORCE.

C. J. S. O'Malley is granted a short service commission as a Flying Officer, for three years on the Active List.

N. I. Smith (Capt., R.A., T.A.) is granted a short service commission as a Flying Officer for three years on the Active List, and is seconded for employment at King's Cross Hospital, Dundee.

*Flight Lt. T. L. P. Harries is transferred to the Reserve,* Class D.2.

## INDIAN MEDICAL SERVICE.

Lt. M. Taylor to be Capt.

The King has approved the relinquishment of their temporary commissions by Capt. Satis Chandra Sen (to retain the rank of Capt.) and Lt. Arukkattur Rangaswamy Srinivasan.

# Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Final Examination of the Conjoint Board, held from Jan. 5th to 27th, the following candidates were approved in the subjects indicated, but are not eligible for diplomas:—

*Medicine.*—M. O. Abdeen, Birmingham; J. R. Armstrong, St. Bart.'s; P. G. Bentlif, Middlesex; T. W. Best, Univ. Coll.; B. Blaxill, St. Thomas's; J. L. Blonstein, Univ. Coll.; Kathleen M. Bowman-Manifold, Royal Free; E. Carew-Shaw, St. George's; Elizabeth J. Carpenter and Rose A. Carter, Royal Free; J. R. B. Chatterton, Univ. Coll.; J. G. Cox, St. Bart.'s; Lucy M. Cranage, Royal Free; K. J. Cursetji and W. W. Darley, St. Bart.'s; L. Dass, Middlesex; P. C. Datta, Calcutta; Mirabel G. Davis, King's Coll.; C. J. Dobbin, Guy's; A. F. Downie, Birmingham; A. G. Eddison, Univ. Coll.; E. S. Evans, St. Thomas's; Alice B. Field, King's Coll.; J. N. C. Ford, St. Bart.'s; R. Gallimore, London; Margaret E. J. Gashion, Charing Cross; R. S. Glennie, St. Thomas's; Marjorie Goldrich, Charing Cross; L. Golomb, Middlesex; A. F. W. Hall, Guy's; R. G. Hall, Charing Cross; Margaret A. Harrison, Royal Free; V. V. H. Ho-Akai, Guy's; Marion Hook, Boston; K. M. N. Isaacs, London; J. H. F. Jayasuriya, Middlesex; Emily E. Johnson, Leeds; J. P. Jones, *St. Mary's; Rachel I. Kessel and Olive C. Knight,* Charing Cross; C. J. Laviers, St. Bart.'s; L. Lipschitz, Berlin and Middlesex; W. H. S. McGregor, St. Bart.'s; R. M. Maher, Liverpool; Marion A. N. Marshall, St. Mary's; Florence I. J. Masterman, Royal Free; A. N. Mathias, St. Mary's; J. H. Miller, Birmingham; E. R. W. Mons-Glaser, Middlesex; Norah M. A. Niall, Charing Cross; Evelyn M. Pakeman, Royal Free; Florence M. Parsons, Charing Cross; Dorothy F. Pratt, Royal Free; Margaret M. Price, St. Mary's; Lesley M. C. Probyn, Charing Cross; W. D. B. Read, Guy's; Sibyl D. Rodgers, King's Coll.; Margaret M. Russell, King's Coll.; J. W. Schollum, Guy's; Helen D. S. C. Scott and Mary A. Silcock, Charing Cross; Evelyn C. N. Strong, Birmingham; Ma May Su, Leeds; B. C. Tate, Birmingham; O. R. Tisdall, St. Bart.'s; E. F. C. Wadge, King's Coll.; I. Waynik, Charing Cross; T. C. S. Webb, Univ. Coll.; and Dahlia Whitbourne, Royal Free.

*Surgery.*—F. Appleton, Manchester; A. K. Basilios, Birmingham; O. H. Bellerby, St. Bart.'s; C. R. Birnie, King's Coll.; J. L. Blonstein, Univ. Coll.; Mabel C. Booysen, Charing Cross; J. D. Borham, Middlesex; J. W. Bottoms, London; G. J. O. Bridgeman, St. George's; A. H. Brockbank, Guy's; A. Burlingham, Univ. Coll.; R. H. Burns, London; C. H. Burridge, St. Thomas's; R. D. W. Butler, Birmingham; Enid Clarke, Royal Free; R. G. Cooke, Liverpool; R. A. P. Corkery, St. Bart.'s; R. F. Corlett, Liverpool; D. H. Couch, Guy's; G. H. Crisp, St. Bart.'s; C. R. Croft, St. Thomas's; T. L. Davies, London; D. A. Dewhirst, St. Bart.'s; Jean M. Dollar, Royal Free; A. G. Eddison, Univ. Coll.; G. Edwards, St. George's; G. O. Edwards, St. Thomas's; R. G. Flower and Elsie G. M. Ford, Leeds; E. J. Greenwood, Guy's; K. A. Hamilton, St. Bart.'s; T. J. Hargest, Cardiff; H. J. Heathcote and T. H. Hobbes, St. Bart.'s; E. G. Howe, St. Thomas's; J. H. ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates have passed the Triple Qualification Examination:—

FINAL EXAMINATION.

John L. Dearberg, Netiamvettil Karumakara Menon, Marian E. Owen-Morris, James K. Steel, *Charles* K. Dowson, Isaac Chesser, Kim Seng Lum, James W. Wylie, William M'Kim, George C. Bergman, Marvel D. Beem, Leonard Barber, Eric D. T. Smith, Alexander Rankin, Robert H. M'Kinnon, Nicandro Valerio, John B. Panton, William T. Baker, Mikhail Younkim, John J. Gilchrist, Sittampalam Thiagarajah, David Dorairaju Nevins Selvadurai, Mela Ram Soni, Douglas B. Cruickshank, Charles J. G. Hunter, William E. Williams, and Asit Chandra Bagchi.

*Medicine.*—Gwendoline R. Andrews, Carapiet Aviet Basil, Surendra Nath Chatterjee, John L. Clark, Wellwattage Liveris Perera Dassanayake, Basil J. Hallion, Samuel A. Hunt, Frederick T. Shadforth, and Thomas A. P. Wynter.

*Surgery.*—William B. Anderson, Basil J. Hallion, David Isaacs, George M. Johnson, Joseph Margolyes, John P. T. Mills, Kenneth R. Scott, Vethanayagam Daniel Seevaratnam, Joseph B. Stromier, Ellis Stungo, Colin H. Wickremesinghe.

*Midwifery.*—William B. Anderson, Gwendoline R. Andrews, Wellwattage Liveris Perera Dassanayake, Harry Ellison, Samuel A. Hunt, George M. Johnson, Tarabai Kalarkar, John Lees, Jemina M. M'Kendrick, William Robinson, William B. Russell, Arleigh W. Scott, Kenneth R. Scott, and Ellis Stungo.

*Medical Jurisprudence.*—Amolak Singh Arora, Alexander W. M. Battersby, Oswald D. Beetham, George V. Boyle, William J. Cudahy, Norman M. Eadie, Anna N. Edward, Armitage E. F. L. Forbes, James Gilchrist, William Graham, *Bandulasena Gunawardena, John* S. T. Isbister, Marcus G. Lucas, James M'Donald M'Kendrick, Ellis Stungo, Necodimus Wijeyesekera, and Malcolm M. Wright.

HOSPITAL SATURDAY FUND.—Awards amounting to £71,503 have just been made to 234 institutions, which is about £1000 more than in 1924. The largest total—nearly £24,000—was given to special hospitals; general hospitals received nearly £10,000, and convalescent homes £6885.

ROYAL INSTITUTION.—On Tuesday next, Feb. 16th, at 5.15 P.M., Prof. J. Barcroft begins a course of four lectures at the Royal Institution on the Egg.

CHELSEA CLINICAL SOCIETY.—A meeting of this society will be held at St. George's Hospital on Tuesday, Feb. 16th, at 8.30 P.M., when Prof. Swale Vincent, Dr. E. Bellingham-Smith, and Dr. T. B. Hyslop will take part in a discussion on the Endocrines.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—A general meeting of this society will be held at 11, Chandos-street, London, W., on Feb. 26th, at 8.30 P.M., when Sir Thomas Horder and Dr. F. W. Price will discuss Syphilis of the Heart, dealing more especially with the early signs and symptoms.

Sir Arbuthnot Lane will deliver an address entitled Is Civilisation a Failure? at the inaugural meeting of the London Clinical Society, which will be held on Thursday, Feb. 18th, at 8.45 P.M., at the London Temperance Hospital, Hampstead-road, N.W. All medical men and women are cordially invited to be present.

MEDICO-LEGAL SOCIETY.—An ordinary meeting of this society will be held at 11, Chandos-street, Cavendish-square, W., on Tuesday, Feb. 16th, at 8.30 P.M., when a paper will be read by Dr. G Halliday Sutherland, on Enlargement of the Prostate in Relation to Criminal Offences, which will be followed by a discussion. Members may introduce guests to the meeting on production of the member's private card.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society will be held at the Municipal Buildings, Glasgow, on Friday, Feb. 19th, at 2.30 P.M., when there will be a discussion on Heart Disease from the point of view of (*a*) public health administration (Dr. A. K. Chalmers), (*b*) the physician (Dr. G. A. Allan), (*c*) the school medical officer (Dr. E. T. Roberts), and (*d*) the factory surgeon (Dr. D. McKail). A paper on Experience at Bradford of the New Notification Clauses *re* Venereal Disease will be read by Dr. J. J. Buchan, and there will be a presentation by the Scottish branch of the portrait of Dr. Chalmers, president of the society, 1913–14. Members attending the meeting will be entertained at luncheon by the Lord Provost and the City Corporation of Glasgow at 1 P.M. Those intending to be present are asked to notify Dr. A. S. M. MacGregor, M.O.H., Sanitary Chambers, Glasgow, as soon as possible.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Feb. 18th, at 5 P.M., a lecture on Artificial Pneumothorax as a Means of Treating Pulmonary Tuberculosis will be given by Dr. R. A. Young at 11, Chandos-street, London, W This lecture will be open to all members of the medical profession.—On Feb. 17th, at 2 P.M., Mr. J. Swift Joly will hold a special clinical surgery demonstration at St. Peter's Hospital, at which all members of the Fellowship or holders of its general course tickets will be welcome.—From Feb. 15th onwards the Queen Mary's Hospital, Stratford, will hold a fortnight's course in general medicine and surgery; there will be demonstrations and lectures in the various departments every day from 10 A.M. till 5 P.M.—During the first fortnight in March the Royal Eye Hospital will hold a special series of clinical demonstrations every afternoon from Monday to Friday inclusive.—During the early part of March there will be a special course in bacteriology at the Westminster Hospital.—The Chelsea Hospital for Women will give a course in gynæcology in the last three weeks of March, with operations, lectures, and demonstrations, and during the last fortnight of the month at the Brompton Hospital there will be an all-day course in diseases of the chest.—From March 15th to 27th there will be a course in general medicine and surgery at the Hampstead General Hospital, to be held from 4.30 to 6 P.M. for the convenience of practitioners.—There will also be a course in tropical medicine, consisting of two sessions weekly, at the London School of Tropical Medicine, beginning on March 16th. Copies of all syllabuses of the general course programme and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

The annual general meeting of the Association will be held, by permission of the Royal Society of Medicine, at 1, Wimpole-street, on Monday, Feb. 22nd, at 5.30 P.M. The business of the meeting will be to receive the reports of the honorary secretaries and treasurer, to elect members of the council, and also to elect the honorary officers nominated by the council at a meeting on June 28th last. These officers are as follows: President, Sir Arbuthnot Lane; Chairman of the Executive Committee, Sir Thomas Horder; Hon. Treasurer, Sir William Hale-White; Hon. Secretaries, Mr. Herbert J. Paterson and Dr. Arthur J. Whiting. By an alteration of one of the by-laws each member of the Fellowship will be entitled henceforth to receive a copy of the Journal of the Fellowship.

RIVERS MEMORIAL MEDAL.—Prof. C. G. Seligman, M.D., F.R.S., has been awarded the Rivers Memorial Medal for 1925 for anthropological work done in the field. This work was in connexion with New Guinea, Ceylon, and the Sudan.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—At a special meeting of the council held on Feb. 4th Lady Barrett, M.D., was elected to the honorary office of Dean of the school.

BRADFORD HOSPITAL AND CONVALESCENT FUND.—Of the £21,490 raised last year by this fund, £12,288 was subscribed by workpeople. In the last 31 years the fund has raised £313,000.

MANCHESTER CHRISTIE HOSPITAL PRIZE LECTURE. Mule-Spinners' Cancer will be the subject of the lecture to be given by Dr. Archibald Leitch in the anatomy theatre of the University of Manchester at 4.30 P.M. on Friday, Feb. 19th.

ST. MARY'S HOSPITAL, PADDINGTON: SPORTSMEN'S COTS.—Last week the Mayor of Paddington unveiled a tablet over a cot provided by the local Sportsmen's Appeal Committee, which has now endowed four beds and two cots with the proceeds of concerts and boxing tournaments.

CITY SMOKE PROBLEM.—Dr. J. S. Owens will deliver a lecture on the City Smoke Problem and the Press at 5 P.M. on Tuesday, Feb. 16th, in the hall of the Institute of Journalists, Tudor-street, London, E.C. Those who wish to be present should inform Mr. L. Gaster, 32, Victoria-street, S.W. 1

TREATMENT OF SURGICAL TUBERCULOSIS.—A course on this subject will be held at the Hôpital Maritime at Berck Plage, Pas de Calais, France, from March 20th to April 3rd inclusive. Lectures will be given in the mornings by Dr. E. Sorrel, and in the afternoons there will be clinical and laboratory work with practical experience in applying plasters and the like. Information may be had from Dr. Delahaye at the hospital.

KING'S COLLEGE HOSPITAL AS MATCH-SELLER.—Commander E. E. Moore, appeals secretary, has placed in the South London area 500 automatic match machines inscribed, "Always buy here; it helps King's College Hospital." The scheme is understood to have originated in Australia, where a large hospital is said to benefit to the extent of between £5000 and £6000 a year by the sale of matches from automatic machines.

LIVERPOOL DENTAL HOSPITAL.—At the annual meeting on Feb. 4th special attention was drawn to the Dental Aid Fund, from which grants are made towards the cost of artificial teeth, fillings, or other appliances supplied to necessitous patients. Last year patients contributed £526, and the subscription list amounted to just under £100. There was a loss of £543 on the year's working, bringing the total debit balance to £3389. This deficit would have been considerably more but for the generosity of Mr. H. L. Cohen, the chairman of the hospital.

SMALL-POX IN DERBY.—As Derby has not been free of small-pox since 1924, the Health Committee intends to ask the Ministry of Health to make regulations under the Public Health Act, 1875, with special reference to power of entry to infected dwellings, power to make house-to-house visitation in infected areas, and penalties for giving false information. The persistence of the disease is attributed to the carelessness and indifference of persons affected or of those responsible for them, to concealed cases, and to the fact that close contacts are not vaccinated. The medical officer of health has been authorised to issue a public warning about the undesirability of large gatherings of children. Isolation hospital accommodation has been taxed to the utmost, and the medical officer of health has had to obtain extra medical assistance.

INTERNATIONAL SOCIETY OF SURGERY.—A congress will be held at Rome from April 7th to 10th of this year by the International Society of Surgery, and the provisional programme has now been issued. The five subjects set down for the scientific sessions are: The Curi-Therapy of Uterine Cancer, the Treatment of Abscess of the Liver, the Surgery of Cerebral Tumours, the Surgery of the Spleen, and the End-results of Jacksonian Epilepsy. Contributions to the proceedings are promised from well-known authorities in France, Spain, Switzerland, Egypt, and this country, the absence of German and Austrian *rapporteurs* being a comment upon the political situation. The congressists will have opportunities of attending operations at the hospitals, they will be entertained by the municipality, excursions have been arranged to Tivoli and Hadrian's Villa, and the Italian members of the society will entertain their colleagues at dinner.

THE death occurred on Sunday last, Feb. 7th, at his residence in Hampstead, of Dr. Henry Rayner, formerly President of the Medico-Psychological Association, and a well-known authority on mental diseases.

VICTORIA HOSPITAL, SOUTHEND-ON-SEA.—Lord Elveden, the borough Member, has given £20,000 and 12 acres of land at Westcliff towards the erection of a new hospital. Some months ago the medical officer of health reported that the accommodation in the present hospital was "grotesquely inadequate," and that the inadequacy was due to lack of financial support. Lord Elveden has inspected many modern hospitals, and the new building is to embody their best features.

NORTH STAFFORDSHIRE INFIRMARY.—Last year the workmen of the district served by this hospital subscribed £27,000. This sum, which exceeds the amount collected from this source in the previous year by £5000, and is more than half of the total income of the hospital, was the result of an appeal for an additional annual income of £6000 to maintain the new extension which will cost £150,000. When the extension is completed it is claimed that this will be the largest hospital outside London.

DONATIONS AND BEQUESTS.—Mrs. E. Rowcroft, of Polmuir, Torquay, has intimated her decision to follow her £100,000 gift for a new Torquay hospital by an additional £13,000 to enable the hospital to start free of debt, the tenders having proved to be in excess of the sum anticipated.—Mr. Isaac Mort, Patricroft, Manchester, left on the death of his wife £500 each to the Manchester Royal Infirmary and the London Hospital, £250 to the Eccles and Patricroft Hospital, £150 to the West Ham Hospital, and £50 each to the Leicester Infirmary and the Heckmondwike Coöperative Society for the medical charities of Heckmondwike.—Mrs. Mary Wellington Elgood, Tenterden, Kent, formerly of Leicester, left £1000 to the Leicester General Infirmary.—Mr. Frederick Whitehead, Oldham, left a legacy of £1000 free of duty to the endowment fund of the Oldham Royal Infirmary.—Mr. Augustus William Summers, Clifton Down, Bristol, left £1000 to the Bristol Eye Hospital, £500 each to Müller's Orphanage, Bristol, the Blue Maids Orphanages, Bristol, and the Home for Little Boys, Kent, £250 each to the Bristol Royal Infirmary and the Bristol General Hospital.

KING EDWARD MEMORIAL HOSPITAL, BOMBAY.—This hospital was opened by the Governor of Bombay on Jan. 22nd. The building has been under construction for five years and is designed on the modern pavilion system. It will accommodate 284 patients and allows for future expansion. It consists of a central administration block, four ward pavilions, two fine theatres, an out-patient department, an ophthalmic hospital, a nurses' home, a maternity wing, a pathological department, a laundry, and servants' quarters. There is also accommodation for eight medical and surgical officers, for a matron, and 50 nurses. Attached is a medical college already completed and in working order. This contains a number of fine lecture-rooms and laboratories, and in addition a hostel to accommodate 100 students. The total cost of college and hospital, together with equipment, is 83 lakhs of rupees and the upkeep is estimated at a recurring expenditure of 6 lakhs. The novel feature of the King Edward Hospital and College is the fact that the medical and surgical work is to be carried on entirely by non-official medical men on honorary lines. No member of the I.M.S. will be on the staff. This is the first institution raised by public funds to work on these lines in India.

ULSTER HOSPITALS.—At the annual meeting of the Belfast Hospital for Diseases of the Skin Dr. S. W. Allworthy reported that skin diseases were largely on the increase, chiefly in consequence of overcrowding and unemployment. A new laboratory is to be equipped for research purposes.—It has become urgently necessary to rebuild the Belfast Hospital for Sick Children on a new site, and an endeavour is being made to raise money for the purpose. At the annual meeting it was lamented that a hospital which had held the premier position in Northern Ireland was now, in consequence of the inadequacy of the building, surpassed by others, some of which are Poor-law institutions. The minimum sum required is £80,000, but the scheme of the medical staff would involve an expenditure of £140,000, towards which only £17,000 is at present available.—The Duke of Abercorn, Governor of Northern Ireland, has opened a new cottage hospital at Coleraine, Ratheane House having been acquired and adapted. The old building has been purchased by Dr. Ranken Lyle, of Newcastle-upon-Tyne, who has given it to Ulster for a maternity hospital and child welfare centre. Prof. J. A. Lindsay, chairman of Belfast Royal Victoria Hospital, describes the new cottage hospital as "beautiful and fully up to the best modern standards." It includes a theatre, a laboratory, and an X ray room.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Births and Deaths Registration.*

ON Feb. 5th Mr. TINNE presented a Bill to amend the law relating to the certification of deaths and the disposal of the dead, which was read a first time.

## HOUSE OF COMMONS.

### WEDNESDAY, FEB. 3RD.

### *Charges by Opticians to Insured Persons.*

Mr. RHYS DAVIES asked the Minister of Health whether he had received representations regarding excessive charges being made by opticians for examination and supply of glasses to insured persons as additional benefits under Section 75 of the National Health Insurance Act; and what steps he proposed to take to prevent any imposition upon the funds of approved societies and the poorest section of the community represented by insured persons.—Mr. N. CHAMBERLAIN replied: I have not received any general representations on this subject, and have at present no power to make regulations with regard to the arrangements or charges for the provision of optical appliances under schemes of additional benefits. The schemes, however, that became operative in July last, following the second valuations, contain provisions enabling an approved society to restrict the cost to its own funds in respect of appliances to such charges as are reasonable. I understand that the general question of the powers of the central department to supervise the provision of this and other additional benefits in the nature of treatment has received the consideration of the Royal Commission on National Health Insurance, whose report I am expecting shortly.

### THURSDAY, FEB. 4TH.

### *Factory Legislation.*

Mr. ROBINSON asked the Home Secretary when it was proposed to introduce the Bill consolidating and amending the Factory Acts.—Sir W. JOYNSON-HICKS replied: For the reasons which I explained in a recent speech it is not proposed to proceed with the Factory Bill during the present session, but it is the intention of the Government that the Bill shall be passed during the course of the present Parliament.

### *The Effect of Disease on Morals.*

Mr. AMMON asked the Home Secretary whether his attention had been called to the case of a youth suffering from the after-effects of encephalitis lethargica, who was recently charged at the Lambeth police-court with stealing a shilling; and would he say what provisions, medical or otherwise, were made to distinguish moral and mental defectives from ordinary criminals brought before the magistrates.—Sir W. JOYNSON-HICKS replied: Yes, Sir. My attention was first called to this case while the lad was in prison on remand, and I asked the Medical Commissioner of Prisons to attend at the court and give the magistrate a full account of the examination made by the prison doctors. The lad was released on probation, and his future welfare is receiving careful attention. With regard to the last part of the question, courts have wide powers of dealing with persons who are certifiable under the Mental Deficiency Act, but persons whose morals have been affected by the disease in question may not be certifiable either under this Act or the Lunacy Acts; and the problem raised by these cases has been engaging the attention of my right hon. friend the Minister of Health, in consultation with the Home Office.

### *Prisoners and Mental Disease.*

Mr. AMMON asked the Home Secretary whether his attention had been called to the sentence of 12 months' hard labour, passed at the Old Bailey on Jan. 19th last, on a man who was certified on medical authority to be suffering from brain trouble; whether he noted the expressed wish of the learned Recorder in passing sentence that Parliament would give judges necessary powers to send such cases to places, other than prisons, where they could get more expert treatment; and would he consider the subject with a view to introducing the necessary legislation.—Sir W. JOYNSON-HICKS replied: Yes, Sir, and I have obtained a special medical report upon the prisoner in question. Upon the information before me, I have no grounds for believing that the sentence passed upon this man was other than appropriate. As regards the Recorder's suggestion that special institutions should be provided for certain offenders who are not insane, I can only say that I will give this question most careful consideration.

### National Health Insurance Report.

Mr. RHYS DAVIES asked the Home Secretary if he was now in a position to state the approximate date upon which the report of the Royal Commission on National Health Insurance might be published.—Sir W. JOYNSON-HICKS replied: I understand it is hoped that the report will be available about the end of the present month.

### Leyton School for Defective Children.

Mr. ROBERT MORRISON asked the President of the Board of Education whether, seeing that the Board recently put considerable pressure upon the local education authority of Leyton to provide a special school for defective children, with the result that the authority had now prepared detailed estimates for providing the school, he would state for what reason the Board have now refused their sanction.—Lord E. PERCY replied: I have asked the Leyton authority to postpone this scheme until it can be considered in connexion with the programmes which I have requested authorities to submit to me, or, in any case, until I have before me the revised estimate of local authorities for the coming year, and arrangements have recently been made for a deputation from the authority to lay their case before my department.

### Milk Deficient in Fat.

Lieut.-Colonel WATTS-MORGAN asked the Minister of Health if he was aware that in the present state of the law no conviction could be secured against any milk vendor, no matter what degree of deficiency in butter-fat or excess of water might be proved to be present, if the vendor was able to produce evidence to prove that the milk was sold as it came from the cow; and if he would take steps as early as possible to secure that milk sold to the public was up to the required standard.—Mr. N. CHAMBERLAIN replied: I am aware that the law is substantially as stated. There are practical difficulties in laying down and applying any fixed standard which would be of advantage to consumers, and, as at present advised, I am not prepared to introduce legislation for that purpose.

### Smoke Abatement.

Mr. CAMPBELL asked the Minister of Health when it was proposed to introduce a Bill dealing with smoke abatement.—Mr. N. CHAMBERLAIN replied: I hope that a Bill on this subject will be introduced on an early date in another place.

### Incidence of Miners' Phthisis.

Mr. DAVID GRENFELL asked the Secretary for Mines whether he was in a position to report on the inquiries into the incidence of miners' phthisis among men engaged in rock-boring with compressed-air machines in coal mines.—Colonel LANE-FOX replied: The inquiry to which I referred in my reply to the hon. Member on July 7th, 1925, has now been completed, and supports the view that in certain rare conditions dry rock-drilling may be dangerous. Certain preventive measures have been suggested as a result of the inquiry, and the inspectors are dealing with the question of their adoption. Medical inquiry is also proceeding to ascertain whether the disease has, in fact, been caused in the places where dangerous conditions have been found.

### Physical and Mental Disability among Air Force Recruits.

Mr. HORE-BELISHA asked the Secretary of State for Air what percentage of new recruits for the Royal Air Force were discharged on account of some physical or mental disability in 1925 within 12 months of their acceptance.—Sir S. HOARE replied: Less than 1 per cent. of recruits were discharged for the cause stated during 1925.

### Dental Treatment of School Children.

Mr. RENNIE SMITH asked the President of the Board of Education whether, in obedience to Circ. 1371 and Mem. 41, the estimate drawn up by the local education authority of Berkshire for dental treatment of children, in consultation with the Board's medical officers, had now been dropped.—Lord E. PERCY replied: The Berkshire authority have submitted revised estimates for 1926–27 showing a reduction in respect of special services, as compared with their previous estimate, but I have received no communication from them indicating that this reduction is due wholly or in part to a postponement of their scheme for dental treatment.

### Physical Deficiency in Naval Recruits.

Mr. HORE-BELISHA asked the First Lord of the Admiralty how many boys and men respectively were accepted in the year 1925 for His Majesty's Navy; how many were rejected on account of some physical deficiency; and what were the corresponding percentages of rejections to acceptances in the years 1910, 1911, 1912, and 1923.—Mr. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: The total boys and men entered in the Royal Navy and Royal Marines during the year 1925 was 1002 and 2970 respectively—i.e., 13 per cent. of those applying. The total number of men and boys "failed" by medical officers during this period was 1753; separate figures for men and boys are not available, and there are no records of the number rejected by recruiters for physical defects. Comparative figures of rejections for the years 1910 and 1911 are not available. During the year 1912–13, of those examined by medical officers (men and boys), 26·20 per cent. were rejected, and acceptances were 30·23 per cent. of total number of applicants. During the year 1923–24, of those examined by medical officers (men and boys), 30·47 per cent. were rejected, and acceptances were 14·83 per cent. of the total number of applicants.

## MONDAY, FEB. 8TH.

### Venereal Disease in Bombay.

Mr. JOHNSTON asked the Under Secretary of State for India whether he was aware that in the Kamatipura district of Bombay there were hundreds of women kept in iron cage houses for prostitution purposes; that the tramcars passed down the street between these cages; that there were instances where from 6 to 12 women were in one room; and that the women solicited from behind the cage bars; was he further aware of the growth of venereal disease in Bombay; and what steps, if any, it was proposed to take in the matter.—Earl WINTERTON replied: I am aware that the horrible practice referred to by the hon. Member in the first part of his question is, unfortunately, too common in the East, though I do not believe it ever reached in Bombay City or elsewhere in British India such a pitch of degradation as the question alleges. The Bombay Government, within whose competence the matter is, passed a law two years ago which should make it far easier to deal with the worst scandals of organised prostitution.

### Driving by the Physically and Mentally Unfit.

Colonel DAY asked the Minister of Transport whether, in view of the fact that there had lately been numerous summonses brought against deaf, dumb, or maimed drivers who, owing to their physical defects, could not observe the rules and regulations of the road for their own or other people's safety, he would introduce legislation or take steps to prevent licences being issued to people who were not entirely physically and mentally fit.—Colonel W. ASHLEY replied: I have the general question of the issue of driving licences to persons suffering from physical disabilities under consideration in connexion with the Bill for better regulation of road vehicles referred to in the Gracious Speech from the Throne.

### Medical Director at Colonial Office.

Mr. RAMSDEN asked the Secretary of State for the Colonies whether it had now been decided to appoint a medical director in the Colonial Office to act as a liaison officer between the Crown Colonies and the Civil Research Committee, and as adviser to him on medical matters.—Mr. ORMSBY-GORE (Under Secretary for the Colonies) replied: The Secretary of State hopes shortly to be able to make a definite announcement regarding the appointment of a medical adviser in the Colonial Office.

### Unhealthy Conditions in Bombay Cotton Mills.

Mr. SCURR asked the Under Secretary of State for India whether he was aware of the unhealthy atmospheric conditions prevalent in the cotton mills of Bombay; and what action the Government of India proposed to take to remedy this defect.—Earl WINTERTON replied: The section of the Factory Report of the Bombay Presidency for 1924 dealing with the subject records some advance in dealing with the problem of atmospheric conditions. The Government of India instituted an inquiry by an expert investigator in 1921; his report was presented in 1923 and has been published. The Government of India subsequently consulted local governments on a number of suggestions for improving the conditions.

### Registration of Nursing Homes.

Mr. GERALD HURST asked the Minister of Health whether he intended this session to appoint a committee to inquire into the desirability of legislation with regard to the registration of nursing homes; and, if so, what type of committee would be set up.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: In accordance with the undertaking given by my hon. and gallant friend, the Parliamentary Under Secretary for Health for Scotland, on June 10th last, steps are being taken for the appointment of a Select Committee to inquire into this question.

### Compensation under Tuberculosis Order.

Brigadier-General CLIFTON BROWN asked the Minister of Agriculture how much compensation money had been paid to farmers under the Tuberculosis Order of 1925; and how many cattle had been destroyed for tubercle under this Act.—Mr. GUINNESS replied: The Tuberculosis Order came into force on Sept. 1st last, and the returns of animals slaughtered under orders from the local authorities up to the end of the year 1925 have only partially been received. It is estimated that during the five months ending about 8000 cows will have been slaughtered, on which about £38,000 will have been paid in compensation.

### *Case of Filaria in India.*

Mr. SCURR asked the Under Secretary of State for India whether he was aware that Narenda N. Bandopadhyaya, a political prisoner, interned last October under the Bengal Ordinance, was now seriously ill with filaria; that he was unable to walk as a result; that the disease had been contracted in gaol; and whether the Government would, in view of these facts, consent to his release on compassionate grounds.—Earl WINTERTON replied: I have not received any information about this detenu's health. But the Bengal Government will certainly have considered all the facts.

## TUESDAY, FEB. 9TH.

### UNQUALIFIED MEDICAL PRACTICE.

Dr. LITTLE called attention to the spread of unqualified practice in medicine and surgery by osteopaths, chiropractors, and other irregular practitioners; and moved "That, in the opinion of this House, an authoritative inquiry with the object of making recommendations to Parliament for dealing with the whole position of irregular practice in medicine and surgery, is urgently necessary." He said that the spread of unqualified medical practice was a fact that must be admitted. The reasons were many, but perhaps the most important was the length of the medical curriculum. It was not true, as was sometimes represented, that British medicine was a system of knowledge confined to the British Islands and the British Empire; it was partly international medicine. It had one distinction—namely, that its students were taught with the patient always in view. Another important quality of international medicine was that any discovery made by one individual was immediately made known to the rest of the world. The note of unqualified practice was secrecy of the methods employed. Osteopaths were most in the public eye at present and were in many respects very different from other groups of unqualified medical practitioners. In the first place, they claimed to be as fully trained in medicine and surgery as were the ordinary students in our medical schools. But nine-tenths of their training was received in the United States. Their system was based on a formula or theory propounded 50 years ago by an obscure medical practitioner in one of the small towns in the Western States of America. That theory had been examined and had been rejected by international medicine and nowhere more thoroughly than in the United States. It had become necessary to grade the foreign colleges from which students came who applied for the right to practise in this country and three grades had been instituted—A, B, and C. Applicants from colleges in Grade A were allowed to sit for an examination set by the licensing body of this country without having done any of the preliminary subjects of medicine or surgery. That fact disposed of the allegation that the medical profession was a very close trade-union which refused to admit any outsiders.

An emphatic rejection of the claims of the osteopaths was that they were not allowed to obtain commissions in the naval and military services of the United States. The osteopaths held that the treatment for ills was the manipulation of the bone structure of the body, and the theory that all disease arose in the spine and might be helped by manipulating the spine was the basis of osteopathy. The five great scourges of the modern world were tubercle, syphilis, malaria, cancer, and insanity. Three out of five of these diseases were regarded by all the world, except perhaps the osteopaths, as being due to bacterial effects. One could see the bacteria which caused these diseases under the microscope. In the case of cancer all the modern work pointed to a bacteriological form, direct or indirect, and a very large number of cases of insanity were unquestionably due to bacteriological effects. In the case of tubercle the damage was greatly increased by the manipulation of tuberculous joints.

With regard to the position of the medical profession in regard to osteopathy, he would liken the profession to the position of a generous and wise wife in a happy marriage. He pictured the husband as the public, and osteopathy as a flighty young flapper of superficial attraction. He understood that the expression "giving the glad eye" had now been raised to the status of a Parliamentary expression by use among the front benches. The "glad eye" had passed between the husband and the younger lady. The wife at home had been not entirely oblivious to that flirtation, but had been prudent enough not to interfere with it in any way. The medical profession was not unduly concerned, and it was not from their point of view that the House ought to approach the subject. It was not the rich, but the poor, who suffered most from this practice. No one could have held, as he had, for nearly 30 years, the position of a hospital physician without being really saddened by the cases that one saw of the terrible neglect of the poor from the point of view of the unqualified medical treatment. He referred to the dispensing chemists, the optician who pretended to be an oculist, and the dentist who was a quack and who fitted new plates upon horrible septic stumps which were poisoning the whole system. No robbery was worse than the robbery of unqualified practice. No spoliation of the poor was more horrible than that. It would astonish the House to learn that, with the exception of England, Germany, and five of the Australian States, practically all the countries of the civilised world penalised unqualified practice. For that reason he asked for an inquiry, which would allow this country to reconsider its standpoint on this matter compared with the rest of the world.

Mr. HILTON YOUNG, who seconded, said that as a matter of public interest they must all feel that the medical and surgical professions were the front line in the trenches in the great war against disease. No effort on their part should be wasted which would tend to the maintenance, discipline, and efficiency of that army.

Mr. ATKINSON said he was unable to accept the resolution which condemned a body of men who were doing work of great value. He would, therefore, move an amendment to provide that the object of the inquiry should be to secure the recognition and registration of manipulative practitioners having approved qualifications. He was asking the House definitely to accept the policy of recognition by registration of persons of approved skill. The committee of inquiry could settle what the necessary qualifications should be; that ought not to be a difficult matter. In America, for example, there were seven colleges under the supervision of the American Osteopathic Association. The standard set there was high. There were hospitals and sanatoria working in America under the same supervision, and it was notorious that their work was done efficiently and well. In 1802 there was only one osteopath in the world. Now, in America, there were upwards of 8000 fully qualified, and hundreds more scattered about the world. Why had not progress been made in this country? Simply and solely because of the opposition of the medical profession. They were all familiar with the notorious case of Dr. Axham, who was hounded out of his profession because he administered chloroform for the most able manipulator. "I remember 25 years ago," continued Mr. Atkinson, "my father being a cripple. He consulted a number of doctors in vain and it appeared as if he would become a cripple for life until he went to see Mr. (now Sir H.) Barker. He was absolutely cured in a short time and he has never been ill since. But the cure involved the most excruciating pain, and in a civilised country suffering of that kind ought not to be necessary when there were such obvious means of preventing it." Why was the country to be denied the service of the osteopath. It was a branch of knowledge which did not form part of the medical curriculum. The ideal way would be for the medical profession in this country to bring it within the medical curriculum, and then persons who showed special skill in that branch of cure could specialise, and the public could have the full benefit of their knowledge.

Dr. SHIELS said he thought that Dr. Little's motion was what military men would call a sort of offensive defensive. Whether that was entirely desirable was another matter, but personally he felt that an inquiry such as the hon. gentleman desired was not necessary at the present time. At the same time he thought that some observation required to be kept on unqualified practice. He objected still more to the terms of the amendment. While the medical profession had derived advantages from the contributions of outsiders, there were definite limits to the extent to which unorthodox practice should be permitted, and that limit was the safety of the public. He thought that the bulk of the medical profession would be prepared to admit that Sir Herbert Barker had performed very considerable services as a practitioner and that he was a man of no mean skill. But Sir Herbert Barker's case was an exceptional one. After all, bone-setting formed a very small part of medicine and surgery, and a general diploma was quite impossible in a case like that. As to osteopathy, the medical profession did not object to it being practised, but they said that before any man should get a medical qualification to practise medicine or surgery on any system he ought to have a definite minimum of fundamental knowledge which was essential.

Mr. N. CHAMBERLAIN (Minister of Health) said that the House would agree that to ask this country to accept diplomas from another country, into the value of which we really could not pretend to examine and over the qualifications of which we had no control, was really not a practical proposition.

Mr. B. PETO said it was hardly accurate to say that he and his friends were asking for American osteopathic degrees to be recognised in this country. The British Osteopathic Association wanted to set up their own college and their own course of training and their own degrees for British subjects, and not to have importations from America.

Mr. Chamberlain said there was no reason why any properly qualified medical man in this country to-day should not specialise, if he liked, in osteopathy. As a matter of fact, some of the most celebrated medical men in this country had done so. Nor was there any reason why the osteopaths should not set up their own colleges; he knew of no reason to stop them. That was the only way, he thought, to achieve what they wanted. If they wanted to have a register of osteopaths in this country let them set up their own colleges, give their own diplomas, and then they would be forced to do what had been done in America. Their curriculum would gradually have to conform to something that would approach to the normal curriculum in this country. He could not vote either for the motion or for the amendment. He did not think it was necessary to prohibit, and he did not think public opinion would be in favour of prohibiting unqualified practice. But the proposals of the amendment seemed impossible to defend, and, on the whole, he thought the House would do best to leave things to develop in the normal, ordinary way.

Colonel Sinclair, who said he was the only member of the General Medical Council in the House, was speaking when the motion was "talked out" at 11 o'clock.

### *Birth Control.*

Mr. Thurtle asked leave to present a Bill to authorise local authorities to incur expenditure, when deemed expedient, in conveying knowledge of birth control methods to married women who desired it. He said that the broad purpose of the measure was to make known to very poor women information which would enable them to restrict their families, such as was at present utilised by wealthier women. Year after year the falling off in the birth-rate became more and more marked in the upper and middle classes, while among the poorer people it was almost stationary. In Westminster the birth-rate was 11·2 per 1000; in Shoreditch 25 per 1000, and in Chelsea 11·3 per 1000. In districts where overcrowding was most rampant and poverty most acute there was a very high birth-rate. The Bill would throw no charge on the national Exchequer and was merely permissive. We were expending money in broadcasting information about sanitation, personal hygiene, diet, tuberculosis, and venereal disease, solely on the grounds of maintaining public health, and there was not a phase in that work that was not rendered more difficult by the fact that in the poorest districts women were having larger families than were good, either for themselves or for the State.

The Rev. J. Barr opposed the introduction of the Bill. He said that in questions like this moral instincts and religious prejudices were as good a guide as conscience itself. If they were defied or ignored it would be at our own peril, and the peril of the State.

Leave to bring in the Bill was refused by 107 votes to 81.

### *Unqualified Optical Specialists.*

Mr. Briant asked the Home Secretary if he would consider the introduction of a Bill to prevent unqualified persons posing as optical specialists.—Sir Kingsley Wood replied: In view of other commitments my right hon. friend is not able to consider the introduction of legislation on this subject.

### *Effects of Stone Dust in Mines.*

Mr. Charles Edwards asked the Secretary for Mines whether he was aware of the number of men in mines suffering from the effects of stone dust; whether he was aware that medical men were certifying this disease and that the numbers were rapidly increasing; whether he had seen the comments of a high court judge on this matter, who spoke of the necessity of scheduling this disease; and whether his department was taking any steps to ascertain the facts in regard to this, with a view to inclusion in the schedule for compensation purposes.—Colonel Lane-Fox replied: On the general question I would refer to my reply on Feb. 4th. It should be emphasised that it is in rare and exceptional cases of dry drilling in siliceous rock that men are exposed to danger, and I have at present no evidence that the number of men affected is increasing. The judicial comments to which the hon. Member refers have not been brought to my notice, but he may rest assured that I am keeping my right hon. friend, the Home Secretary, in close touch with the results of my investigations.

---

The fiftieth birthday of the Association pour l'Avancement des Sciences will be celebrated at a congress to be held at Lyons this year. From July 24th to August 1st there will be an international exhibition of "all that relates to applied science."

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, Feb. 15th.—4.30 P.M., General Meeting of Fellows. Special Discussion on Focal Sepsis as a Factor in Disease.

Tuesday.—5.30 P.M., General Meeting of Fellows. 5 P.M., Therapeutics and Pharmacology. Laboratory Meeting at Guy's Hospital. Prof. C. S. Gibson and Mr. H. Burton: The Trypanocidal Action of some New Organic Arsenic Compounds. Prof. A. L. Gibson and Prof. C. S. Gibson: Demonstration of Hortvet's Apparatus for Cryoscopic Determination. Dr. E. P. Poulton: Demonstration of a New Method of Administering Oxygen. Mr. J. H. Ryffel, Mr. A. A. Osman, and Mr. W. W. Payne: Prophylactic Use of Alkalis in Anuria. 8.30 P.M., Pathology.

Wednesday.—5 P.M., History of Medicine. Mr. E. Muirhead Little: Glisson as an Orthopædic Surgeon. Colonel W. P. MacArthur: Some Notes on Old-time Leprosy; the Case of King Robert the Bruce.

Thursday.—5 P.M., Dermatology. (Cases at 4 P.M.). Dr. H. W. Barber: Dermatitis Scrofulosa. Dr. M. S. Thomson: Syringo-Cyst Adenomata. Dr. E. G. Ffrench: Lupus Erythematosus.

Friday.—8.30 P.M., Electro-Therapeutics. Dr. E. P. Cumberbatch: Experiences on a Tour of Physiotherapy Clinics in America.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.

Monday, Feb. 15th.—9 P.M., Dr. E. Farquhar Buzzard: Principles of Treatment in Relation to Diseases of the Nervous System. (First Lettsomian Lecture.)

MEDICO-LEGAL SOCIETY, 11, Chandos-street, W.

Tuesday, Feb. 16th.—8.30 P.M., Dr. G. Halliday Sutherland: The Enlargement of the Prostate in Relation to Criminal Offences. To be followed by a discussion.

CHELSEA CLINICAL SOCIETY, St. George's Hospital.

Tuesday, Feb. 16th.—8.30 P.M., Discussion on Endocrines. Speakers: Prof. Swale Vincent, Dr. E. Bellingham-Smith, and Dr. T. B. Hyslop.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

Thursday, Feb. 18th.—8.15 P.M., Dr. Patrick A. Buxton (Milner Research Fellow with the New Zealand Government): The Depopulation of the New Hebrides and other Melanesian Islands.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

Monday, Feb. 15th.—5 P.M., Mr. Stanford Cade: Cholecystography.

Wednesday.—5 P.M., Dr. Alfred Piney: The Importance of Hæmatology in Surgery.

Friday.—5 P.M., Dr. Piney (lecture concluded).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

Monday, Feb. 15th, to Saturday, Feb. 20th.—Fellowship of Medicine lectures, Medical Society, 11, Chandos-street, W. Thursday, 5 P.M., Dr. R. A. Young: Artificial Pneumothorax as a Means of Treating Pulmonary Tuberculosis. Wednesday, 2 P.M., Special Clinical Surgery Demonstration at St. Peter's by Mr. Swift Joly. Open to Fellowship members and ticket holders only.—Queen Mary's Hospital, Stratford, E. Special Post-graduate Course in General Medicine and Surgery. Sessions daily from 10 A.M. till 5 P.M., Operations, Demonstrations, Lectures.—London Lock Hospital, Dean-street, W. Clinical Course. Instruction daily in the O.P. Department.—Combined Children's Course, Paddington Green Hospital, Victoria Hospital (Tite-street, Chelsea), and the Children's Clinic, Conway-street, N.W. Morning and afternoon sessions daily.—London Temperance Hospital, Hampstead-road, N.W. 4.30 to 6 P.M., Special Course for General Practitioners. Further information from the Secretary of the Fellowship of Medicine.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

Thursday, Feb. 18th.—4.15 P.M., Dr. Charles Singer: The History of Rickets (third of four lantern lectures, open to medical students of the University of London).

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

Tuesday, Feb. 16th.—5 P.M., Dr. J. H. Sequeira: Tuberculosis Cutis (I.).

Thursday.—5 P.M., Dr. Ingram: Pathological Demonstration.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, Feb. 15th.—10 a.m., Surgical Out-patients: Mr. W. E. Tanner. 10.30 a.m., Gynæcological Operations: Mr. A. E. Giles: Throat, Nose, and Ear Operations: Mr. W. Ibbotson. 2 p.m., Medical, Surgical, and Gynæcological Clinics, Operations. 6.30 p.m., Venereal Department.

Tuesday.—2 p.m., Medical, Surgical, Throat, Nose, and Ear Clinics, Operations. 4.30 p.m., Mr. N. Fleming: Corneal Conditions.

Wednesday.—10.30 a.m., Surgical Operations: Mr. E. Gillespie. 2 p.m., Medical, Eye, and Skin Clinics, Operations. 5.30 p.m., Venereal Department.

Thursday.—10.30 a.m., Dental Out-patients: Mr. E. S. Pierrepont. 2 p.m., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 p.m., Operations.

Friday.—10.30 a.m., Eye Operations: Mr. N. Fleming. 2 p.m., Surgical, Medical, and Children Clinics, Operations. 3 p.m., Gynæcological Clinic. 6.30 p.m., Venereal Department.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: February–March, 1926.

Clinical Lectures and Demonstrations.

Monday, Feb. 15th.—2 p.m., Out-patient Clinic: Dr. Hinds Howell. 3.30 p.m., The Aural Causes of Vertigo: Mr. Just.

Tuesday, Feb. 16th.—2 p.m., Out-patient Clinic: Dr. Walshe. 3.30 p.m., Cranio-cerebral Topography: Mr. Armour.

Thursday, Feb. 18th.—2 p.m., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 p.m., Testing the Eighth Nerve: Mr. Just.

Friday, Feb. 19th.—2 p.m., Out-patient Clinic: Dr. Adie. 3.30 p.m., Surgery of the Spinal Cord: Mr. Sargent.

The fee for the Course, including Pathology Lectures, is *£5 5s.* *For those who hold Perpetual Tickets the fee is £3 3s.*

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 a.m., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.

Wednesday, Feb. 17th.—Dr. Harrison: Tests of Hepatic Efficiency.

Thursday.—4 p.m., Dr. Shires: X ray Diagnosis of Diseases of the Chest.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

Thursday, Feb. 18th.—5 p.m., Mr. C. S. Lane-Roberts: Ectopic Pregnancy.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.

Wednesday, Feb 17th.—5.30 p.m, Mr. E. H. Drinkwater: Some Conditions Influencing the Choice of Anæsthetic.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday, Feb. 19th.—4 p.m., Dr. Nicol Rankin: Purulent Rhinitis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

Friday, Feb. 19th.—3.30 p.m. (at the Royal Hospital), Dr. Grout: Radiological Examination of Gastro-Intestinal Disease.

## Appointments.

**Lack, V. J.**, M.B., B.S., F R.C.S. Edin., has been appointed Assistant Obstetric and Gynæcological Surgeon to the London Hospital.

**Melville, Mary Ashcroft Jessie**, M.B., Ch.B. Glasg., House Surgeon, Victoria Hospital, Keighley.

**Roberts, T. E.**, M.B , B S. Lond., D.P.H., School Medical Officer for Portsmouth.

**Tylecote, F. E.**, M.D., D.P.H. Vict., F.R.C.P. Lond., Honorary Physician to the Manchester Royal Infirmary.

**Viner, Geoffrey**, M.D. Lond., F.R.C.S. Eng., Honorary Consulting Ophthalmic Surgeon to the Watford and District Peace Memorial Hospital.

## Vacancies.

*For further information refer to the advertisement columns.*

*Birmingham General Hospital.*—Part-time Clin. Asst. in Ven. Dept. £350.

*Birmingham, Queen's Hospital.*—Third P. for Out-patients. £50.

*Bradford City.*—Asst. Bacteriologist. £600.

*Brighton, New Sussex Hospital, Windlesham-road.*—H.S. At rate of £50.

*Bristol General Hospital.*—Two H.P.'s., two H.S., Res. Obstet. O. and Cas. H.S. All at rate of £80.

*Bristol Royal Infirmary.*—Hon. S.

*Canterbury, Kent County Mental Hospital, Chartham.*—Jun. Fourth Asst. M.O. and Pathologist. £300.

*City of London Hospital for Dis. of the Heart and Lungs, Victoria Park, E.*—H.P. At rate of £100.

*Derby, County Mental Hospital, Mickleover.*—Jun. Asst. M.O. £400.

*Exeter, Royal Devon and Exeter Hospital.*—Res. Cas. O. At rate of £100.

*Hampstead General and North-West London Hospital, Haverstock-hill, N.W.*—H.P. Also Cas. M.O. Each at rate of £100.

*Highgate Hospital, Dartmouth Park Hill, N.*—Sen. Asst. Med. Supt. £400.

*Holloway Sanatorium, Virginia Water, Surrey.*—Med Supt. £1000.

*Hospital for Consumption and Dis. of Chest, Brompton, S.W.*—Anæsthetist.

*Hyde Borough.*—M.O.H. £800-50-1000, plus travelling expenses.

*Johannesburg, S. African Institute for Medical Research.*—Pathologists. £1200, £1000, and £600 respectively.

*Leeds Public Dispensary.*—Sen. Res. M.O. £200.

*Leicester Royal Infirmary.*—H.S. At rate of £125.

*London County Council.*—Sen. M.O. £1219 12s.

*London Hospital, E.*—Vacancy on Hon. Surg. Staff.

*Manchester, Ancoats Hospital.*—Res. M.O. Also H.S. At rate of £150 and £100 respectively.

*Manchester, St. Mary's Hospitals.*—Res. Obstet. O. and Res. Surg. O. Each £200.

*Northampton General Hospital.*—H.P. and H.S. Each at rate of £150.

*Norwich, Norfolk and Norwich Hospital.*—H.S. £120.

*Royal Chest Hospital, City-road, E.C.*—S.

*Royal College of Surgeons of England.*—Election to Court of Examiners.

*Royal Free Hospital, Gray's Inn-road, W.C.*—Second Asst. to Venereal Diseases Clinic.

*St. Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.*—H.S. at rate of £200.

*Saint Pancras Dispensary, 39, Oakley-square, N.W.*—Res. M.O. £175.

*St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.*—H.S. At rate of £75.

*Salford Royal Hospital.*—Radiologist. £300.

*Samaritan Free Hospital for Women, Marylebone road, N.W.*—H.S. At rate of £100.

*Shrewsbury, Royal Salop Infirmary.*—H.P. £160.

*Stoke-on-Trent, North Staffordshire Royal Infirmary, Hartshill.*—Asst. Hon. S.

*University College Hospital, Dental Dept., Great Portland-street, W.* Hon. Anæsthetist.

*West Bromwich and District Hospital.*—Res. H.S. £220.

*West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.*—Sen. H.P. At rate of £150.

*West London Hospital, Hammersmith. W.*—Asst. Path. £350. H.P. and two H.S.'s. Each at rate of £200.

*York County Hospital.*—H.S. £150. Also H.S. for Eye, Ear, and Throat Dept. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments for Certifying Factory Surgeons: Alston, Cumberland: Cerrig-y-Druidion, Denbighshire; Haslemere, Surrey: Sherburn, Yorks, E. Riding.

## Births, Marriages, and Deaths.

### BIRTHS.

**Gebbie.**—*At Boston Bank, Hyde*, Cheshire, on 7th inst, to Dr. and Mrs. N. Gebbie—a daughter.

### MARRIAGES.

**Phelan—MacDonald.**—On Feb. 6th, at South Kensington, Major E. C. Phelan, D.S.O., *M.C.*, R.A.M.C, to Mrs. MacDonald, widow of Ian MacDonald, Highfield, Southampton.

### DEATHS.

**Bateson.**—On Feb. 8th, after a short illness, at the Manor House, Merton, S.W, William Bateson, F.R.S., Director of the John Innes Horticultural Institute, Hon. Fellow of St. John's College, Cambridge, aged 64.

**Gorrie.**—On Feb. 5th, in a nursing home, following an operation Henry James Gorrie, O.B E., L.R.C.P. and S., L.D.S., Edinburgh, in his 46th year.

**Hoyle.**—On Feb. 7th, at Glenroy, Blundell avenue, Porthcawl, Dr. William Evans Hoyle, late Director, National Museum of Wales, and of Crowland, Llandaff.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## THE VOLUNTARY MENTAL PATIENT.

BY NORMAN R. PHILLIPS, M.D BRUX.,
SENIOR ASSISTANT MEDICAL OFFICER, ST. ANDREW'S HOSPITAL FOR MENTAL DISEASES, NORTHAMPTON.

THE Royal Commission on Lunacy and Mental Disorder has now for some time been conducting its inquiries. It is clear, from the evidence made public, that the dissatisfied element has been given a fair hearing. It is to be hoped that equal consideration has been given to the more modest and retiring type of patient who shuns publicity and who is frequently grateful for the treatment he receives. That there are two sides to every question is no less true of the mentally afflicted. In these days it would be difficult to imagine any large collection of men or women which did not include a certain element of unrest, and it would be strange indeed not to find it in our hospitals for the insane. The only difference between the sane and the insane agitator is one of degree. Up to a certain point the agitator is tolerated by society. As soon, however, as he becomes dangerous to himself or others he is liable to be placed in an asylum. Many of these cases originally suffered from delusions of persecution and have later become persecutors themselves. Referring to this class of patient, Stoddart says: "When they find themselves sequestrated in an asylum, they are a plague to the institution. They criticise the routine, get up trumpery charges against the attendants, and write complaints against the medical officers to the Board of Control." Owing to lack of judgment they cannot understand that they are insane, and consequently they consider themselves illegally detained.

In this article I wish to draw attention to a very different type of patient from the one just mentioned. The sceptical person who visits a mental hospital expecting to find patients wrongfully detained is not only surprised at finding none, but is still more surprised when he meets with patients pleading in the most reasonable manner to be allowed to remain in the institution, and not to be given their freedom against their will. There is a definite group of patients who are never so well or free from mental trouble as when they are safely inside a mental hospital. Not a few of them have a sincere wish to be detained on a permanent basis. As far as they are concerned internment is final, it is in fact their only means of defence against themselves. In such cases the asylum—using the word in its true etymological sense—is a shelter from insanity which attacks them as soon as they are discharged. If allowed to return to society they become the inoffensive dupes of humanity. It may truly be said that liberty is the cause of their insanity, and they dread it because of their inability to adapt themselves to it. Paul Courbon gave the name of liberty psychosis (*psychose de la liberté*) to this type of insanity. "As soon as they are obliged to live an independent existence," he says, "they lose their self-control. Under the supervision of a protector they retain their reason. Liberty is the principal cause of their losing their mental balance." Investigation into their previous history will demonstrate the fact that many of these individuals were always of a timid and retiring disposition, dreading any responsibility in life, deficient in initiative, and, above all, lacking in judgment. As long as they can lean on someone possessing that energy which they themselves lack, they can conduct themselves normally, but when they are deprived of this support it becomes necessary for them to seek protection in a suitable institution, otherwise they rapidly lose their reason. There is increasing evidence to show that this psychopathic condition is largely due to faulty education by narrow minded parents or guardians. After a course of treatment in a mental hospital has helped them to regain their mental balance they are so gratified that it is not uncommon for them to wish to remain indefinitely rather than run the risk of again facing the world and its trials.

### *Clinical Record*

As an example I will quote the following case which has come under my observation.

Miss A., aged 53, admitted as a voluntary boarder into St. Andrew's Hospital in April, 1923.

*Previous History.*—One of a family of eight. At age of 10 years adopted by grandparents who lived in a country vicarage. She attended school until she was 17, when they removed to another small village. Her grandmother, who was 70 years old, had very narrow views. She completely dominated her young protégée, who was not allowed to do anything that could be done for her. She had even interfered with her school lessons, and arranged for her to be put in a class with older girls who were above her standard. She was left to sit still or potter about while her guardian superintended the work in the house or garden. Any initiative she showed was discouraged, and she gradually came to distrust herself, and to feel that she was as helpless as she was ignorant. She had bouts of depression at times, and would complain of a tired feeling and of aches and pains. There is no doubt that suggestion helped largely to produce these latter symptoms. As she herself says: "I was brought up to think it interesting to be delicate. My grandmother frequently told me that she was delicate herself in her younger days, and that she considered it vulgar for young ladies to be robust." Moreover, she frequently came in contact with invalids and "nervy" people—"it was fashionable to be an invalid at X." It is difficult to imagine anyone more unfitted to fight life's battles alone. Fortunately, when her grandmother died at the age of 86, she was able to return to her mother's care, where she found a very different state of things. The other members of her family had been brought up to do something useful in the world. Her younger sister, who managed the household duties, resented the intrusion of so incapable a person, and had not the patience to teach her how to work. By arrangement she was sent to stay with different families as paying guest, and she did a little light work. She knew she could always return to her mother, which she did frequently. The friction with her sister, however, became more and more acute, and culminated in the patient leaving home for good. The shock at this final separation from her mother was too great, and within a few weeks she lost her mental balance. She came to the conclusion that she was no good to anybody and never would be, and that the best thing she could do would be to disappear. She made an ineffectual attempt to drown herself. Asked if she would go to a mental hospital for treatment, she willingly assented.

*Condition on Admission.*—Physical health good; no signs of organic nervous disease.

*Mental.*—She was depressed and morbidly apprehensive. She was solitary and retiring, and lacking in self-confidence. Referring to her recent attempt at suicide, she said: "I felt I'd proved I was incapable of fighting life's battles alone, and I wanted to take strong measures."

For a while she was treated by rest in bed and psychotherapy. Four weeks after admission she was moved to a villa in the grounds. She gradually got more self-confidence and became less depressed. She occupied herself with reading, writing, and needlework. I now suggested she might do some weeding in the garden. This she took up with increasing zeal, saying it helped her to forget herself. Occasionally she would become depressed after an interview, lest she might have to leave. She told me that the discipline and order of the hospital had the restraining influence which she lacked when out in the world. Though her garden work was at first supervised, she began to show increasing aptitude and initiative. She gradually became so reliable that for some considerable time she has practically had charge of a large garden, which now looks better cared for and more beautiful in the summer than ever before. The patient also busies herself in other ways—especially dressmaking. She enters into the games and various entertainments. For some time she has had parole, which enables her to go unaccompanied into the town and country round, and to do her own shopping. During the first year she was liable to occasional attacks of depression, but she has been free from these for some time past. She still, however, shows apprehension at any suggestion of her leaving the institution.

The above case is merely an example of the type to which I wish especially to call attention. It may not be easy to point out another case exactly similar to this one. But there are a great many which resemble it in many respects. The same timidity, want of self-assurance, and incapacity to lead an independent existence is met with in men as well as in women, in younger as well as in older individuals. The fact that the poor are as liable to be affected as the rich is in favour of extending the voluntary boarder system to our public mental hospitals. When women of this type marry they may become just as dependent on their husbands for protection as they were formerly dependent on their parents; and the loss of the husband may in like manner be responsible for a mental collapse. It must not be supposed that all patients of this class are necessarily admitted into our mental hospitals as voluntary boarders. The mental breakdown, when it does occur, may necessitate certification. Nevertheless, because of their willingness to remain and coöperate in the treatment they are potentially voluntary boarders.

### *Prophylaxis.*

The more closely one investigates the family history in such cases the more one becomes convinced that the principal ætiological factor is faulty environment. Preventive treatment, if it is to be effectual, must therefore begin in the homes and schools. It is not the child so much as the parents and school teachers who require treatment. If they are to develop normally, the child's mental faculties and natural energies must be allowed greater freedom of action instead of being stifled by vexatious interferences and unnatural restraint. Children should be brought up to face life and extract from it and themselves the best possible results. The importance of these principles has long been recognised in America by the National Committee of Mental Hygiene, and it is interesting to note that a similar society has recently been formed in this country.

### *Treatment.*

Though prophylactic measures on the lines mentioned would probably save any amount of treatment in after years, it should be borne in mind that it must of necessity take a considerable time before mental hygiene could possibly establish itself sufficiently in this country to be of any general practical value. It is our duty, therefore, to apply the best therapeutic remedies at our disposal when the patient is eventually brought to the hospital. All treatment should be directed to encouraging the patient to develop those faculties and energies which have been unduly restricted in the past, with the ultimate object of his gaining sufficient confidence to lead an independent existence. The patient may be induced to discuss his difficulties and worries, but it is obvious that, where the cause is largely environmental, little good can be expected from psycho-analysis. On the other hand, suggestion may be employed with advantage. It is most important to obtain the coöperation of the patient in the various stages of the treatment.

The case above described serves to illustrate the benefit which may be derived from occupational therapy. There is no doubt that there are greater possibilities in this method of treatment than are at present generally realised. The remedy is an old one, but of recent years it has been extended and developed as a result of the experiences of the war. The various exercises and games, &c., as well as the musical and dramatic performances arranged for our patients have undoubtedly a stimulating and beneficial effect. It is, however, claimed (and I think with reason) that the benefits to be derived from productive work are often more substantial and more enduring than those produced by the diversional activities just mentioned. In some of our private mental hospitals it is the custom to let the patient buy a plot of ground and sell the produce to the institution. The advantage of this arrangement is that it enables him to see the marketable value of his work, and this in itself promotes a spirit of initiative and self-reliance. It is a good principle to encourage and reward the patient for work done by a gradual extension of privileges. Granting "parole," which enables him to go for walks unaccompanied in the hospital grounds, and, in suitable cases, in the town and country, is as a rule much appreciated. Later this may be extended to permission to visit friends for gradually increasing periods of time. By employing such methods as these it may, in course of time, be found possible to wean the patient from hospital control.

My thanks are due to Dr. D. F. Rambaut for permission to publish the notes of the above case.

## BRIGHTER BIOCHEMISTRY.

"The chymists are a strange class of mortals impelled by an almost insane impulse to seek their pleasures among smoke and vapour, soot and flame, poisons and poverty." This very proper quotation is to be found upon the title-page of *Brighter Biochemistry*, the illustrated journal of the Biochemical Laboratory at Cambridge. But the quotation does not stop there. "Yet among all these evils," it continues, "I seem to live so sweetly that I may die if I would change places with the Persian King."

And such is the spirit—strange as it may seem—which inspires the third annual number of this witty and amusing production. There are many illustrations, which are chiefly relevant to the personnel of the Sir William Dunn Institute. Most of the humour is local and there is perhaps an excess of it. But in spite of this anyone who has even a moderate knowledge of biochemistry and a sense of humour should enjoy it thoroughly. Cambridge journalism has not produced anything better within recent years. "The Dunnsday Boke" and the report of the holder of the *Brighter Biochemistry* Travelling Fellowship for 1925 are particularly pleasing, whilst everyone will like to see the pictures of Langerhans discovering his islands (complete with a Blue Lagoon and Emmeline and Dick) and of Lawes and Gilbert feeding their pigs.

Copies may be had for 2*s.* 6*d.* from the Editors, the Sir William Dunn Institute, Tennis Court-road, Cambridge.

## A CALL TO MEDICAL ESPERANTISTS.

We have received the first number of a new volume for 1926 of the *Internacia Medicina Revuo*, the official organ of the Tutmonda Esperantista Kuracista Asocio (Universal Esperanto Doctors' Association), which contains a stirring appeal from the pen of Dr. W. Robin, of Warsaw, asking medical esperantists to send to the review accounts of original work by their colleagues in various parts of the world. He points out that unless medical work is reported in an English, a French, or a German journal it is frequently overlooked. Among the articles in the current issue of the review is one by Dr. Maksimiljano Blassberg, of Cracow, on the progress and trend of medical treatment: one on the fight against venereal disease in the United States by Dr. F. Ulman, of Prague; and one dealing with immuno-therapy and protein therapy by Dr. J. Kostrzeski, of Cracow. There are several short original communications, together with editorial extracts from foreign medical journals. The *Revue* is published in France, from rue de la Bassée, 31, Lille, and general inquiries should be addressed to Dr. Briquet there. Original articles should be sent to Dr. Robin, Marszalkowska, 113, Warsaw, Poland, and extracts from medical journals to Dr. Blassberg, Starowislna ul, 18, Cracow, Poland.

## "EMERGOPLAST."

This is a ready-for-use wound dressing made by Messrs. Edward Taylor, Ltd., of Salford and London. It consists of a strip of medicated gauze with an edging of adhesive zinc oxide plaster which is protected by a covering of muslin. For use the plaster is cut up in suitable sizes and the muslin cover stripped off, thus leaving a piece of gauze with an adhesive strip of plaster on two opposite sides of it. The dressing can be applied to a wound in a moment and the medicated gauze, which may contain iodoform 10 per cent., boric acid 15 per cent., or double cyanide, according to requirements, absorbs the discharge and supplies a disinfectant. Each kind of "Emergoplast" is packed in a box containing one yard 2½ inches wide. The idea is excellent.

## THE "CONSTANTE" TRUSS.

Messrs. Alexander and Fowler, of 104 and 106, Pembroke-place, Liverpool, have submitted to us a patent truss which deserves careful trial. They claim that it conforms to the mechanical adaptation of the human hand in its application to the control of hernia. This claim is based on the fact that the band or spring is so constructed that it merely provides a means of holding the hernia pad in place, pressure being obtained by means of a finely tempered spring working independently at the end of the band. This spring may be altered in position so as to give pressure at various points of the pad according to individual requirements. Where it is desirable to limit the outward movement of the pad a rigid finger control-piece is added. By a special gauge the proper amount of pressure for each case can be ascertained and a suitable spring selected.

## MANCHESTER ROYAL INFIRMARY.

The annual report states that the number of patients treated during the year was 57,499, compared with 54,731 in 1924. These included 11,047 in-patients, 17,222 dispensary patients, 26,347 accident-room cases, and 993 venereal diseases clinic out-patients. The daily average of beds occupied by in-patients was 543; the average stay of patients was 17·68 days, and the cost per occupied bed per annum was £165 1*s.* 1*d.* The operations performed numbered 9053. The expenditure was £114,031, an excess of £22,740 over the income. The total number of beds is 1250, made up of 688 in the Royal Infirmary and its central branch, 132 at Barnes Convalescent Hospital at Cheadle, and 430 in the Royal Mental Hospital and branches. There has been a progressive increase in the number of cases treated in the accident-room at the infirmary and at the central branch, from 19,491 in 1922 to the present total of 26,347. The daily average is now 75, as against 50 in 1920. The board of management is faced with a serious difficulty, as the infirmary is not in a position to cope with the increasing demands made upon its in-patient accommodation. At the beginning of the year 1152 persons were awaiting admission to the wards; at the end of it the number had increased to 1682. The situation becomes more acute every year, and the infirmary is able to cope with surgical cases only in emergencies which admit of no delay. For the new nurses' home £150,000 are required, and at the close of the year £45,650 had been received. To diminish the present working hours of the nurses—which are 63 per week for the day staff and 73 for the night staff—to 56 hours, it will be necessary to increase the staff by 157 nurses and domestic servants. The present staff comprises 220 nurses and 113 maidservants. It is intended to make provision in the new home for a total additional staff of 370—257 nurses and 113 maids. The medical superintendent of the Royal Mental Hospital at Cheadle, in a separate report, states that there were 257 patients there, as against 253 in the previous year; 66 voluntary-boarders were admitted during the year.

# Lettsomian Lecture

ON THE

# PRINCIPLES OF TREATMENT IN RELATION TO DISEASES OF THE NERVOUS SYSTEM.

*Being the First Lettsomian Lecture in 1926, delivered before the Medical Society of London on Feb. 15th,*

By E. FARQUHAR BUZZARD, M.D. Oxf., F.R.C.P. Lond.,
PHYSICIAN TO ST THOMAS'S HOSPITAL.

When honoured by an invitation to deliver the Lettsomian lectures, I was naturally impelled, in the first place, to increase my knowledge of the personality and the work of John Coakley Lettsom. This was not a difficult task, as I found a short notice of him in the "Imperial Dictionary of Universal Biography" and a very delightful sketch of his life and character written by a past President of the Society, Sir StClair Thomson, in the forty-first volume of our *Transactions*. From the former article little can be gleaned in regard to Lettsom's personal traits, except that as a dresser at St. Thomas's Hospital "he distinguished himself by that diligence and steady conduct which were ever his great characteristics," and that his sense of humour was evinced by the epitaph he wrote for his own tombstone:

When people's ill, they comes to I;
I physics, bleeds, and sweats 'em.
Sometimes they live, sometimes they die;
What's that to I? I Lettsom (lets 'em).

In the second line of this short verse he summarises the methods of treatment at the disposal of a physician of his day; in the next he refers tersely to the results of treatment in words which are equally applicable to our own efforts. It is difficult to believe that Lettsom owed his phenomenal success to his astuteness in prescribing, his skill in blood-letting, or to the perfection of his methods of promoting diaphoresis, and we must seek elsewhere for an explanation.

From the information provided for us by Sir StClair Thomson we learn that Lettsom could lay no claim to scientific knowledge greater than the average of his generation, which can only be described as meagre and shallow; but it is equally evident that he possessed untiring energy and industry, wide interests in a variety of subjects and pursuits, unbounded generosity, and a sympathetic understanding of human nature—a combination of gifts which brought him more fees and fame than any other medical man of his time. In spite of his ignorance of the doctrines of Freud and Jung, his psychotherapy must still have been the most powerful weapon in the armament he employed for attacking disease, or, shall we say, for treating patients.

Perhaps it was the train of thought provoked by the study of Lettsom's career that led me unwarily to undertake the task of reviewing the principles which guide us, or should guide us, in dealing with diseases of the nervous system in the present state of our knowledge. For, while it is true that psychotherapy is still the most valuable weapon we possess for every-day use in our array of remedial agents, the century and a half separating us from Lettsom in his prime have provided us with a host of others of which he can never have dreamed.

### QUACKERY.

It is interesting to note that in spite of the comparatively limited therapeutic resources at Lettsom's disposal, and notwithstanding the advances which have been made since his day in the science of medicine, particularly in regard to its anatomical, physiological, bacteriological, and biochemical aspects, the rivalry of quackery remains practically undiminished, if, indeed, it has not increased. Sir StClair Thomson quotes the following passage from a letter written by Lettsom in 1787:—

> "Among the people of fashion in London, quackery is cultivated. Can one wonder at lying advertisements, when it is known that Garrick, Lord Lonsdale and the Bishop of London were for awhile the patients of Meyerbach (a German quack). These were men of sense; but what is the intellectual state of our nobility? Perpetually enslaved by the novelty of fashion, however outré, they acquire a constitutional propensity to imitation in everything; and leave the physician as they quit an old coat."

This indictment of society, perhaps without its personalities, has stood the test of time and is still regarded generally as a true bill by members of our profession.

How is it that orthodox methods of treatment, which have steadily gained in range, accuracy, and efficacy, have hardly done more than hold their own in the eyes of the public against the striking though evanescent reputations enjoyed from time to time by quacks and quackeries? It is easy to answer this question by asserting, and with some measure of truth, that there is no limit to the ignorance and credulity of the public in medical matters, but can we boast that we have used our position of authority to best advantage in the way of educating our lay brethren and gaining their confidence? There may be two opinions as to the advisability, or, indeed, the possibility, of educating the public up to a standard of medical knowledge high enough to be helpful in dealing with this problem. In other and less intricate matters the public is content to abide by the advice of the experts whom it employs. We are not all learned in law, engineering, architecture, or agriculture, nor do we value our smattering of knowledge of these subjects so highly as to feel justified in posing as critics of those who have made them their life's study. It is hardly likely, therefore, that in medicine, requiring as it does a long training, not only in its own principles but in those of other preliminary and essential sciences, the layman can ever aspire legitimately to a position from which he is competent to speak with critical authority. Although this consideration is never likely to stifle the incompetent critic, it may stimulate some of us to question how far attempts to educate the public in medical lore should be promoted. It is hardly necessary to point out that public enlightenment in hygiene and preventive medicine may be encouraged without the risk which attends a superficial insight into the pathology, symptomatology, diagnosis, and treatment of disease.

If it is impossible to educate our patients sufficiently in medicine to enable them to realise the advantages of treatment governed by scientific knowledge over that which depends on ignorance and credulity for its acceptance, it is clear that we must find some other method for establishing and maintaining our position of supremacy in relation to that occupied by our unqualified rivals. We must find some method by which the confidence of the public in our knowledge and practice can be won and preserved. Our conviction that we hold all the trump cards in our hands avails us little if we cannot play them with skill enough to win the tricks.

### *The Relation of the Profession to the Public.*

It may be asked, not unreasonably, how is the topic to which I am directing attention germane to the subject of these lectures. I would answer this question in two ways. In the first place it is essential, in order to apply principles of treatment with success in practice, to hold the confidence of those who are submitted to treatment. In the second place it is my intention, while discussing various disorders of the nervous system from a therapeutic standpoint, to review in a critical spirit the measures of treatment in general use with special reference to their effect on the confidence and respect of our patients. It can hardly be claimed that the relationship between our profession and the public at the moment deserves to be described as an entente cordiale, nor can we honestly assert that the blame for this lack of mutual understanding lies entirely with the public. An atmosphere charged with currents of doubt and mistrust is not congenial to our work or favourable to its success, and if I can contribute any suggestions towards the creation of better climatic conditions, I am prepared to run the risk of an occasional burst of indignant thunder. It has been said that our objective in life should be "to kill lies without hurting men," a twofold ambition of which one component is about as difficult to attain as the other, and a task which may ask too much of a physician without the assistance of an anæsthetist.

A first great step would be taken towards the creation of a better atmosphere if it could be noised abroad that we physicians, I cannot speak for surgeons, have no pretensions to curing disease, and that, although we claim some understanding of morbid processes and disorders of function, we are in a position only to act as Nature's allies and agents. Let the claim to cure disease be made only by the unqualified. In these days the difficulties confronting a medical man in treating his patients are greatly increased by the additional task of treating and satisfying the patient's relations and friends. Illness is no longer discussed in whispers in a bedroom; it forms one of the chief subjects of discussion at the tea and dinner table, and advice is accepted, not from the doctor alone, but from all and sundry who are willing or eager to offer it. All the more reason, therefore, that the measures we adopt, the advice we give, and the information we impart to the patient and his family should be based on sound foundations and capable of standing the tests of time and doubt.

### *The Precedence of Diagnosis.*

The first principle of treatment, and I need hardly say that this does not apply only to disorders of the nervous system, is the precedence of diagnosis. This obvious truism, to which no medical man will take exception in theory, gives rise to at least two important questions of which the first is: "What is really meant by a diagnosis?" and the second "In what proportion of cases is this principle acted upon?"

A diagnosis is, or should be, much more than a label; it should inform its maker's mind of the pathology and natural history of the morbid process indicated by its name. The doctor's responsibility does not end with labelling a patient's disorder and prescribing treatment. He should be in a position to describe in general terms the nature of the malady, the course it is likely to take, as well as the objective and probable effects, if any, of the measures he may recommend. It is true that the patient is content with a name, of which he thinks he knows the meaning but does not, and insists on having some form of treatment. In this respect the osteopath has an advantage over us. He has only one diagnosis and one treatment for all the ills to which human flesh is heir. A bone out of place is the diagnosis; its replacement the treatment. The simplicity of the whole thing is what appeals to the lay mind; its absurdity appeals only to our sense of humour.

### *A Label and a Treatment.*

But before passing judgment on the osteopath let me remind you of the kind of letter every consulting neurologist receives at least once a week:—

DEAR A,—I have made an appointment for Mrs. B to see you. She came to me three months ago complaining that she could not use her right hand properly. I could not make out much wrong, and her reflexes were normal. I called it neuritis and ordered her massage and electricity which did no good. Then I gave her "hormotones" with a negative result. Since then she has been to an osteopath. I should be glad of your opinion and advice.—Yours truly, C.

No history of the patient's disability and no diagnosis; a label and a treatment. I am not suggesting that in all cases of the kind the patient has suffered in the sense that valuable time has been wasted. I do submit, however, that the massage and electricity and hormotones are as good examples of quackery as the osteopath's bloodless surgery, and that Mrs. B and her relatives can hardly be blamed if they fail to recognise a difference between qualified and unqualified practitioners. I can hear C's defence. He does not pretend to know anything about nervous diseases, and although he suggested a second opinion months ago, Mrs. B would not consent. If he had insisted she would probably have left him and gone to D. But in the long run would it not have been to C's advantage and all for the good of our profession's reputation that she should go to D? If such principles as "diagnosis before treatment" guided all members of our profession, as many of D's patients would come to C as of C's to D.

Let us suppose that Mrs. B was suffering from the early manifestations of Parkinson's disease, and let us suppose that the diagnosis had been made and the following advice given her:—

"You are suffering from a disorder of the nervous system for which there is no cure known. It may progress slowly or it may remain stationary for a long time but it is unlikely to improve. It does not affect the mind and it does not lead to paralysis and the horrors you associate with that word. You will find that it makes you slower and more awkward and perhaps shaky in your movements. Massage will only make you feel a little less stiff for a short time; electricity is useless. Certain drugs may make you more comfortable and perhaps lessen the shakiness, but on the whole, you will be well advised to carry on with your activities to the best of your ability and to place little or no reliance on treatment. You will be urged by your friends to try this, that, or the other cure, but each would only lead to another disappointment, impress your trouble more firmly on your mind and certainly waste your money."

Mrs. B would adopt one of two courses. Probably she would disregard the advice, waste time and money on all sorts of cures recommended by her friends, and perhaps in the end regret her lack of confidence in her doctor. Possibly she might accept the situation and succeed in keeping on top of her disability; at any rate, she would be saved the misery of the alternating hopes and disappointments which are the lot of those who seek cures for incurable disease. Is it not possible that if we were, one and all, to give advice to our patients on the lines I have indicated and to run the risk of losing a few of them, the time would come, and at no great distance, when the public would listen with confidence to our words of wisdom and would realise that they must turn to the science of medicine, not to quackery, for help and guidance in times of need.

We all of us denounce quacks, some would legislate against them, and, I fear, many imitate them, but I am convinced that only by raising our standard of practice in proportion to our knowledge, and by holding and living up to ideals foreign to our competitors, can we hope to win the public respect which is due to a scientific profession. Competition between qualified and unqualified practice would cease to exist with the cessation of any similarity between the methods they adopt, and the public, not the profession, would reap the greater benefit from the change.

Having thus cleared the air, as it were, by laying an indictment, not so much against unscrupulous quacks nor against a misguided, press-ridden, and over-credulous public, but against our perhaps too-satisfied selves, and by suggesting a curative treatment which *may* be Utopian and is certainly difficult to carry out, I propose to draw attention to matters of more practical moment.

### LESIONS OF THE UPPER MOTOR NEURONE.

Let me begin by a consideration of the principles which should guide our treatment when confronted by disorders of function involving the upper motor neurone.

For the purpose of illustrating various points of importance, I will take for my text a straightforward case of right hemiplegia resulting from a vascular lesion in the neighbourhood of the left internal capsule. With the treatment of the patient's cardio-vascular condition we are not here concerned, but three or four days have elapsed since his "stroke," he is fully conscious, and is confined to bed with his right arm and leg flaccid and paralysed.

Experience teaches us that immobilisation of the limbs favours the formation of adhesions in their joints, especially those of the shoulder, hip, and knee. Our first duty, therefore, is to instruct the nurse to move all the joints of the paralysed limbs in all possible directions at least three or four times in every 24 hours. Foreseeing also that with the gradual return of tone to the muscles the limbs will tend to assume certain fixed postures, instructions must be given to the nurse that they are not to be allowed to remain in any one position for many hours at a time, and that pillows, or perhaps sandbags, should be employed for the purpose of counteracting the postural tendencies. It is particularly desirable to combat the tendency of the arm to become strongly adducted at the shoulder by placing a pillow in the axilla and to prevent the preponderating tone in the flexors and pronators at the elbow from imposing their authority in regard to the position of the forearm. At frequent intervals, and for some hours at a time, an attitude of extension should be maintained at the elbow, wrist, and finger-joints. In the lower limb similar precautions will be necessary to prevent it assuming a fixed position of adduction and internal rotation at the hip with extension and inversion at the ankle.

The precautionary manipulations I have indicated can be carried out by any nurse without special training. It is the doctor's knowledge of what is likely to happen in their absence and his directions to the nurse which are of paramount importance. Very shortly two things will happen. The patient will realise that he can make some movement, probably of his leg; the patient or his family will ask: "When do we start massage and electricity?" This is the crucial moment in relation to the patient's subsequent progress and welfare, the moment when the doctor needs to summon the scientific knowledge he possesses to his aid and to use it for the education of his patient. It is, indeed, to the education of his patient during the next few weeks that he must apply himself if the best possible result is to be attained.

### *Principles to be Observed in the Education of the Patient.*

May I recall to the doctor's mind some of the essential facts underlying the principles which must be his guide in this process of education. The lesion which has paralysed the patient is one involving the upper motor neurones and therefore has not directly interfered with the normal function of any muscle in the paralysed limbs. There is a failure on the part of the patient to carry out certain voluntary movements; there is no failure on the part of the muscles and no blame attaches to them. This is not a theory but a fact which can easily be demonstrated to the patient in numerous ways. If he is observant he will, perhaps, have noticed already that when he yawns his seemingly paralysed arm makes a movement comparable to the "stretch" of his sound limb, that when he makes a big effort with his left side certain involuntary movements occur in his right limbs which he cannot reproduce separately at will. When you tap his tendons the muscles contract briskly and strongly, and if an electric current is applied to them they respond in normal fashion. Noxious stimulation of the sole of the foot or of the palm of the hand may give rise to widespread movement quite outside the patient's control. The evidence is overwhelming, therefore, that there is nothing the matter with his limbs or their muscles, and therefore nothing to treat in them.

And yet in 75 per cent. of cases massage and electricity will be ordered for the limbs and the patient led tacitly to understand that they are the agents responsible for his recovery. It may be granted that, as I have already pointed out, some simple passive movements are desirable in order to prevent complications and that a little rubbing will promote the circulation in limbs which are apt to get cold and stiff as the result of their immobilisation; but electricity! If all the current wasted in a year on the limbs of hemiplegic patients could be stored in accumulators, the Prime Minister's scheme for supplying electricity to the country would be rendered superfluous! Must we really go on allowing and even encouraging the public to believe that electricity has some magic influence in restoring nervous energy to paralysed limbs or that it has any curative properties whatever. Is not its use in some departments of medicine as unjustifiable and useless as osteopathy, homœopathy, chiropraxy, or the like?

But to return to the patient and his education. Let me give the gist of what he must be told, not, perhaps, all at once, but in varying language and on many occasions until he has thoroughly mastered his lesson.

"In health when you wish to make any particular movement of a limb, your brain sends an impulse by nervous paths to muscles, or groups of muscles, which contract and so carry out the movement you desire. As the result of your illness there is some obstacle in the way of impulses passing from your brain to your right arm and leg. You have the desire to make a movement and the impulse is started but it does not reach the limb. You might think that the fault lies in the muscles or joints of your arm or leg but that is not the case. They are perfectly healthy, as I can demonstrate to you, and are ready to perform the movements you desire so soon as you can succeed in sending the necessary impulses to them. As far as we know, there is no reason why the obstacle to the passage of impulses should not be overcome, as a result partly of Nature's power of healing and partly of your own efforts. You must not expect any treatment applied to the limbs in the way of rubbing or manipulations to help in restoring your power of moving them. The object of the masseur is to keep the muscles and joints in good condition until such time as you can make use of them yourself. This is a case in which you, although the patient, have to carry out the greater part of the treatment yourself and you cannot depute the task to anyone else.

"We shall want you to devote a few minutes, several times a day, to making attempts at movements, in other words, to sending impulses on their way. But this must be done in a systematic manner if it is to achieve the quickest and best results. It is not much good saying to yourself, 'I will move my arm' or 'I will move my leg' heedless of what movement, if any, results. Study the movements which you can carry out at each joint in your sound limbs and attempt to repeat each one on the other side. You have already succeeded in bending your elbow very slightly; this movement will be retained and grow stronger every day. You need not bother so much about the movements you have acquired but give more attention to those which are still lacking. You cannot bend your wrist as yet, but look at it several times a day and make the mental effort to bend it and one day it will answer to your call."

I have repeated this lesson in order to submit that it indicates, in a few words, practically all that can be said in regard to the principles of treating patients with lesions of the upper motor neurone. To leave the patient without this enlightenment is to neglect our chief responsibility; to tell him more is to embark on the task of educating someone who lacks the elementary knowledge essential for its accomplishment.

Other and perhaps more cogent reasons for emphasising the importance of such a lesson are, first, the infrequency with which it is taught, secondly, the valuable results I have observed to follow its teaching. After all, what is the value of our knowledge if we do not make full use of it? Ignorant of medical science, any layman when confronted with inert limbs jumps to the conclusion that something must be done to them to restore their life and that massage and electricity are the obvious agents for that purpose. Why should we pander to such ignorance and descend to the level of the quack?

I am quite alive to the fact that the masseur of the present day is often intelligent enough to encourage his patient to carry out movements against resistance, and by so doing, to enlist his interest in his paralysed limbs, which is the first therapeutic requirement. But in ninety-nine cases out of a hundred the patient is convinced that it is what the masseur does to him and not what he does himself which is responsible for his gradual return of power. I can hear the question asked: "What does it matter what the patient thinks so long as he improves?" In my opinion it matters a great deal from the point of view both of the patient's pocket and of our professional reputation. Moreover, it has often happened to me when seeing hemiplegic patients that I have been able to demonstrate their ability to perform voluntary movements of which they were quite *unaware even after months of massage.*

The principles governing the treatment of hemiplegia are, as I have already said, equally applicable to all conditions in which the upper motor neurones are at fault, whether the lesion lies in the brain or in the spinal cord. In many instances the patient's activity is as much interfered with by the development of spasticity as by the impairment of his voluntary power; indeed, it is not unusual to find a sufficiency of voluntary power for practical purposes defeated by the presence of hypertonus. Various surgical procedures have been advocated for the purpose of reducing this handicap, but the success which has attended their practice has only been of limited range and in selected cases. Looked at from the physiological point of view, we must still base most of our hope on the persevering efforts of the patient who, by gradually developing the inhibitory influence of his upper neurones, may do much to keep in check the reflex mechanism responsible for involuntary spasms. For this reason we are again obliged to enlist the patient in his own service and to admit that there is little we can do to supplement his own systematic efforts. If there is one thing to be avoided in such cases it is the application of electricity, an agent which, if it has any influence, can only be in the direction of increasing reflex irritability.

### LESIONS OF THE LOWER MOTOR NEURONE.

The principles which should guide us in treating patients suffering from lesions of the lower motor neurone are simple and easily defined, although they must necessarily be modified in practice by our knowledge of the nature and natural history of the lesion in any particular case. The lower motor neurone differs from the upper in the fact that it has *to do with individual muscles and not with voluntary movements*, and in its ability to regenerate after injury so long as its cellular element is not destroyed. In some diseases, therefore, we can entertain the hope that nature's efforts may restore normal function, or at any rate succeed in bringing about some measure of recovery. In others we are faced by the certain knowledge that death has overtaken the essential cells and that nothing can be done to bring them back to life.

The acute specific fever which we recognise by the name of acute poliomyelitis may be usefully employed as an example of a lower motor neurone lesion on which our principles of treatment can well be based. Let us take, for instance, the case of a child about 10 years of age, who suffers from an acute illness, with the usual disturbances of health associated with an acute specific fever, and who develops a widespread and flaccid palsy of two or more limbs. The illness may last but a few days, at the end of which time the patient is unable to utilise his right arm and leg. Two or three weeks later, quite irrespective of any treatment, it will be found that the patient has recovered the power of contracting certain muscles in the paralysed limbs, while other muscles not only fail to respond to volitional efforts, but exhibit the reaction of degeneration to electrical stimulation, and are obviously losing their normal bulk and tone.

The upper limb will serve to supply us with all the material necessary for the question of treatment. We find that function has returned in the small muscles of the hand, the flexors of the wrist and fingers, and in the extensors of the elbow. The spinati, deltoid, biceps, and extensors of the wrist show no sign of life. In other words, the brunt of the inflammation in the spinal cord has fallen on the fifth and sixth cervical segments. The disease has run its course and is a thing of the past. Certain muscles have recovered their ability to contract in obedience to the patient's will and may be left to regain their former strength without anxiety. What can be done about those which *show no signs of life except their ability to respond* to the make and break of a galvanic current?

The mischief in the cord has been done, and we have no means of restoring to life cells which may be destroyed. We know of no method by which we can help to restore the function of those neurones which are *not destroyed but only temporarily crippled.* We must be content, therefore, to keep the paralysed parts in so healthy a condition that any restoration of function in the nervous paths may find the muscles, tendons, and joints fit to undertake their task once more. Immobilisation is the chief danger threatening the joints and this can be easily averted by daily passive movements of the simplest kind. These movements will also insure against any tendon becoming unduly shortened by any fixation of the limb which we may be obliged to resort to. What about the muscles? Their nutrition can be maintained by keeping them warm and by rubbing, and their contractility perhaps promoted by applying such electrical stimulation as will cause them to contract. Finally, we must remember that a muscle which, having lost its tone, remains passively stretched for any length of time will not recover its function even when its nervous connexions with spinal centres have regained their normal activity. In our particular case the weight of the limb hanging by the patient's side will tend to stretch the paralysed and toneless deltoid and biceps, and unless this mechanical strain is avoided it will be hopeless to expect those muscles to recover their function. A splint, removable to allow of daily joint movements and muscle rubbing, must be devised to keep the arm abducted at the shoulder, the elbow flexed, and the wrist extended, the positions in which the deltoid, biceps, and extensors of the wrist are maintained in a condition of relaxation.

The measures I have described comprise all that lies in our power to promote the restoration of function in muscles put out of action by lesions of the lower motor neurones, and may be applied to all conditions in which hope of such recovery is justified, such as injuries to peripheral nerves or peripheral neuritis. On the other hand, the length of time during which these measures should be persevered with must vary with the nature of the lesion. In the case of acute poliomyelitis it is customary to teach in general terms that treatment should continue for a year or 18 months after the acute illness. This may be true if all cases, including those who have not been treated from the beginning on the principles I have indicated, are included. If, on the other hand, we take cases which have received efficient treatment from the onset, those muscles which show no return of function at the end of four to six months will not develop a sufficient amount of power to be of any practical use, however long massage and electrical treatment may be continued.

A general recognition, therefore, of the principles governing the treatment of patients suffering from the effects of acute poliomyelitis would result in a considerable economy of muscular energy, electrical current, time, and money. When the conclusion is arrived at that no more restoration of muscular power can be expected, further treatment must depend on the particular disability of each case and on what orthopædic measures can be devised to reduce the disablement to a minimum. No general principles governing these procedures can be laid down; anything from a simple tenotomy to a complicated mechanical support or an arthrodesis may be required.

### *Motor Neurone Degeneration.*

This is a modern term denoting progressive muscular atrophy, bulbar palsy, and amyotrophic lateral sclerosis. The condition is, as its name implies, one in which there is a gradual but progressive degeneration or dying out of all the chief efferent tracts. In all three types both upper and lower motor neurones are involved in the process of decay, but in the two first named the muscular atrophy resulting from the loss of lower motor neurones is the predominant clinical feature. We are entirely ignorant of the cause of this disease and equally powerless to arrest or even influence its course. Although the rate of progress is variable, there is no proof that methods of treatment which are generally applied either hasten or postpone the inevitable fatal termination. It might be said, therefore, that since all treatment is valueless, there can hardly be principles which govern it. But something may be said in regard to the handling of these terribly distressing cases, something which may help the public to distinguish the practice of the profession from that of the quack. The diagnosis having been made, what information should be imparted to the patient and his relations? Something must be said and some advice given, but what? There appear to be two alternatives which I will indicate in language of my own choosing. In the first place, you may say to the patient:—

"Some of your muscles are wasting and becoming weak. You must have some massage and electrical treatment to strengthen them and I will give you some injections of strychnine in order to tone up your nervous system."

*No promise of cure, true; but a suggestion, a strong suggestion, that* the measures you prescribe will bring about some amelioration. Result after one, two, or three months' treatment varying with the sufferer's patience and pocket—certainly no better, probably rather worse. "The doctor evidently does not understand my case and I will try an osteopath recommended by Lady X" Osteopath, more straightforward than the doctor, promises a cure, but it means a long course of treatment and payment in advance, *a suspicious symptom overlooked* by the patient. His diagnosis, treatment, and failure are all foregone conclusions, and we need pursue this patient's miserable adventures no further. Suffice it to say that, looking back on his experiences, he is unable to distinguish that which he underwent with his own doctor from that with the osteopath except in one not unimportant feature; the osteopath has been paid and the doctor is still hoping!

The alternative *method is to address the patient* in some such terms as these:—

"As you see for yourself, your hand is weak because some of the muscles have wasted. As a matter of fact, the fault does not lie in the muscles themselves but in some of the nerve cells which ought to nourish them. These cells have decayed before their time just as some people's hair goes grey or their arteries become hard sooner than usual. It is a process with which we are quite familiar, of which we don't know the cause and for which there is no reliable remedy. The muscles *which have withered will not regain their* size or power, and other *muscles may become affected* in a similar manner, but such an event may be long postponed. In order to put as little strain as possible on these obviously fragile tissues, I shall advise you to save yourself all unnecessary muscular exertion. Don't be led *into the belief that* exercising these failing muscles will increase their size or *power.* It is true that healthy muscles will respond in that way, but that is because both they and the nerves which nourish them are healthy For the same reason avoid electrical treatment and injections of drugs like strychnine which will not do good and quite possibly may do harm. It is no good whipping tired horses and *it is still more useless* to stimulate tired muscles and nerves. On the other hand, gentle massage might be helpful in maintaining the nutrition of what muscular tissue is left although you must not regard it as a curative measure You have nothing to fear in the way of pain. Although the condition is not without danger, I have *known* patients who have lived many years in spite of it and whose lives have not been shortened by it."

These words contain the truth, perhaps the whole truth, and certainly nothing but the truth. Whether they are accepted is not our co cern. We have done all in *our* power not only to help the patient physically, but to save him from the mental anguish which follows on disappointment and which is *far* more distressing than any bodily disablement. We have given him the opportunity of making once and for all his psychological *adjustment* to whatever fate has in store for him and of avoiding the suffering engendered by false hopes *and* cruel disillusions. Further, and of less importance, the event, whether our advice is heeded or unheeded, will vindicate our professional knowledge and the knowledge of our profession.

In this *my* first of three lectures I have chosen for discussion some disorders of nervous function the causes of which we are powerless to influence or control. The problem of treatment in each instance, using the word treatment as covering all that concerns the patient's welfare, has been the application of certain principles derived from our knowledge of what natural forces can do and how, from a physiological and anatomical point of view, these forces can be aided and abetted. But on the foundation provided by these principles, I have based an appeal for the more serious consideration of two of our many responsibilities. Of these the first is our responsibility for the psychological as much as for the physical health of our patients even when they are the victims of organic disease; the second is our responsibility for raising the standard of our practice as high as is *possible above that of quackery, so that sooner or* later the public may have no room *for doubt as* to where to place their faith.

# Remarks
## ON THE
## RÔLE OF THE MESENTERY IN VISCERAL DISORDERS.

*A Lecture delivered at the London School of Medicine for Women*

BY H TYRRELL GRAY, M.CH. CAMB,
F R.C S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, *GREAT ORMOND STREET, ETC.*

THIS subject was chosen in order to emphasise that the mesentery receives too little attention in the study of visceral disease. It is a subject which clearly covers so much ground that it is impossible, in the allotted time, either to consider every aspect or to enter into any great detail.

In the first place we should realise that, though the gastro-intestinal tract possesses a large measure of independence and autonomy, it is of no physiological value without its mesentery. In it are contained —

(*a*) *Arteries and veins*, which not only ensure the vitality of the gut, but, in the latter case, are *designed for* absorption of the foodstuffs prepared for assimilation *and for* the removal of waste products.

(*b*) *Lymphatics*, which exercise the dual function of absorption and the removal of waste products.

(*c*) *Nerves*, both motor, inhibitory, and *sensory*. These exercise a governing control, in accordance with the needs *of the body, on the otherwise* independent movements of the gut. To some extent also they synchronously influence the digestive secretions.

It is obvious that *a structure of* such vital importance should be elaborately provided with means of defence, the *breakdown* of which must interfere with vital processes and lead to a variety of visceral disorders. Some of these I propose to discuss this evening in the hope that a departure from the beaten track may stimulate your interest and provoke discussion.

The *defence* of the mesentery against damage to its contained structures is of two kinds:—

(*a*) *Against Infection*.—This is provided by the lining of peritoneum with its endothelial cells. This, as you are well aware, is endowed *with bactericidal* properties manifested by the outpouring of serum and lymph formation. I do not propose to refer in detail to a subject *so* familiar to you all.

(*b*) *Against Mechanical Injury*.—This occurs under pathological conditions in *two ways—i.e.*, pressure and tension. The means of protection against mechanical injury are: (1) fat and areolar tissue contained in the mesentery; (2) the tone and development of the abdominal muscles; and (3) the mesenteric Pacinian corpuscles.

### DEFENCES OF THE MESENTERY AGAINST INFECTION.

Peritonitis may be general, diffuse, or localised, depending on the virulence of infection and the degree of resistance. When the parietal *peritoneum* alone is involved the overlying muscles are on guard and rigid; but apart from constitutional symptoms there is no associated gastro-intestinal disturbance. When, however, the inflammatory process involves the mesentery the afferent and efferent nerves are irritated, and the Pacinian corpuscles are also involved. From this certain characteristic symptoms arise which are to be taken as indications of a defensive mechanism. This is best illustrated by concrete examples.

*Acute Appendicitis.*—You are familiar with the classical symptoms and signs in typical cases. But, if the appendix itself is sensitive (or responsible for the symptoms for which it is blamed), how is it that in one instance vomiting is pronounced and in another absent? Why is one subject constipated and in another the motions are normal, &c.?

Consider first the appendix adjacent to the ileal mesentery. Inflammation involves the mesentery of the ileocæcal angle and irritates—

(1) *The Pacinian Corpuscles.*—From these proceed:

(*a*) *Pain*, which is generalised over the mid-abdomen, since the hyperæmia extends for a variable extent over the ileal mesentery. The localisation of pain later to the right iliac fossa is an indication of the extension of inflammation to the parietal peritoneum in the vicinity.

(*b*) *Afferent impulses*, eliciting an efferent response along the somatic nerves to the abdominal muscles. This results in the abdominal rigidity or "guarding" with which you are familiar; and which, together with thoracic respiration (i.e., limitation of abdominal movement), is clearly a defensive measure.

(2) *Efferent Nerves.*—The stimulation of these in their course by the inflammatory process results in inhibition and immobility over the area of gut supplied—the ileocæcal angle. As you know, it is difficult physiologically to stimulate the vagus in its efferent course, because the sympathetic dominates. The same is true clinically, so that the affected viscera are kept at rest. The result is that *constipation* is characteristic.

(3) *Afferent Nerves.*—The efferent response to this is manifested by efferent sympathetic stimuli resulting generally in closure of the pylorus and a generalised inhibition and immobility of the intestinal tract. At the same time the afferent vagus stimulus elicits gastric contraction through its efferent response. The result is vomiting and an accentuation of constipation with gradually increasing distension.

If these symptoms be contrasted with a similar inflammation of a retrocæcal appendix (when the mesentery is intact and there is no involvement of vagus or sympathetic) it is noticeable that vomiting is rare and the bowels are often normal, while rigidity is absent, until the peritoneum is involved by direct extension. Similarly in acute salpingitis these symptoms are absent until the mesentery is involved.

This mechanism is obviously designed to achieve the first principle in the treatment of inflammation—i.e., *to rest the inflamed part.* Thus the inhibitory impulses immobilise the bowel and limit the spread of inflammation; and this is assisted by the motionless abdominal wall. Vomiting and pyloric closure prevent food entering the intestinal tract and ensure rest. For the clinician the moral is obvious—namely, to assist by imitation this defensive mechanism; and this is the principle of the Fowler treatment. The removal of the appendix with the minimum disturbance (Murphy said "quick in and quick out"), followed by starvation, rectal saline and glucose, and morphia are best calculated to achieve the maximum of rest. To these I would add radiant heat and fomentations for reasons to be discussed later. Purgation is wrong in principle. As the inflammatory process subsides the intestines will begin to move again, and then the action of the bowels can be assisted by a wash-out and pituitrin.

*General Peritonitis.*—This is only an exaggerated example of the one discussed. Clearly the whole intestinal tract is involved, and the symptoms are more severe and the distension very much greater. Finally, the "ileus" may be sufficiently pronounced to constitute a serious condition in itself. So-called "paralytic ileus" deserves separate consideration.

### DEFENCES OF THE MESENTERY AGAINST MECHANICAL INJURY.

1. *Pressure: Paralytic Ileus.*—We have already seen that ileus may be produced by sympathetic stimulation, and that this is a defensive measure calculated to provide rest for the inflamed part. To call this "paralytic ileus" is a misnomer, since it is active inhibition. But it may easily develop into a true paralytic ileus. As the intra-abdominal pressure rises *the most collapsible structures will be first effected*—i.e., the *veins*. Increasing pressure on the veins leads to progressive venous stasis. You all know that muscle becomes rapidly fatigued and cannot contract unless its arterial and venous circulation is intact; so that, engorged with venous blood, intestinal muscle becomes inert and distension is accentuated. It is clear that "active ileus," if I may so term it, whether originating primarily from infection, or from mesenteric injury (as in post-operative ileus) may progress towards a true "paralytic ileus." *And the point to note* is that the latter is vascular in origin.

While the treatment of active ileus is rest, the treatment of paralytic ileus must be amplified and is directed to:—

(*a*) *Circulation.*—The withdrawal of blood from deeper structures and the efficiency of the heart's action are the first step. *Radiant heat:* There is no more efficient treatment than repeated radiant heat baths to the abdomen for 20 minutes or half an hour at a time, and renewed hot fomentations. These are followed by 1 c.cm. of pituitrin hypodermically and a turpentine wash-out. This is frequently followed by the passage of flatus, and again by slow distension. Frequent passage of the flatus tube is also of value, and small doses of morphia are indicated. The use of radiant heat to the abdomen (originally taught to me many years ago by Sir George Makins) has proved invaluable; but I am often surprised to find how seldom it is employed. The heart's action should be ensured by the usual stimulants.

(*b*) *Diminution of Intra-abdominal Pressure.*—Repeated attempts to secure the passage of flatus has been mentioned, and will succeed directly the circulation is sufficiently restored to permit of muscular contraction. It is useless to employ purgatives. *Gastric lavage:* This is another valuable means of reducing intra-abdominal pressure. In the majority of instances the condition will gradually yield to treatment along these lines. Where, however, the ileus is intractable and distress is great, more active steps must be taken. *Spinal anæsthesia* has been known to be followed by the passage of flatus and fæces, probably by reason of the complete abdominal relaxation it induces. *Temporary ileostomy:* This is most valuable as a means of reducing intestinal distension and intra-abdominal pressure. Arbuthnot Lane advocates opening the abdomen and suture of the skin alone—i.e., establishing a ventral hernia—in order to reduce pressure. Other instances of paralytic ileus of vascular origin are to be found in the terminal distension associated with lobar pneumonia, right heart failure, &c.

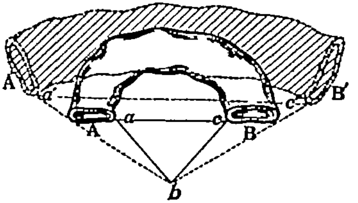
2. *Mesenteric Tension: Local Ileus.*—As an introduction to this subject I may first emphasise the difference in symptoms between intestinal obstruction and strangulation. In the former complete obstruction may exist for days, or even a week or so (if gradual in onset), without marked constitutional disturbance. Often the tongue is moist and fairly clean, the complexion may be good, &c.; in fact, there is often little general evidence of serious trouble. Thus the complete retention of intestinal contents, *colic and distension, may fail* markedly to impair the general health. Contrast with this the rapidity with which the pinched face, rapid pulse, intestinal breath, subnormal *temperature*, sunken eyes, and vomiting are established within a few minutes of acute strangulation. The acute pain and vomiting at the onset are due to the sudden injury to the mesentery by the strangulating agent (in contrast to the insidious onset when only part of the bowel wall is nipped—e.g., Richter's

hernia); but with the passage of the initial symptoms is ushered in a rapid and progressive illness. In a very short time the most striking symptoms are the dry, brown tongue and the fœtor of the breath, which are characteristic of an intestinal lesion.

Now this contrast should tell us that the retention of intestinal contents (or intestinal stasis) per se is greatly over-rated as a cause of the symptoms referred to. You are all familiar with the effect of ligaturing the veins of a loop of gut while leaving intact the arterial supply. In strangulation the veins, being most collapsible, are occluded; and, as in the experiment, the venous pressure rises. I suggest that the passage of serum and gases from the blood into the occluded loop continues until the pressure here exceeds that in the adjacent veins which are not occluded. Such gases will be rapidly passed into the circulation, carried to the lungs and exhaled. As the strangulated loop becomes gangrenous it forms a focus of continuous and progressive toxic absorption. These causes of rapid absorption do not exist in obstruction of the intestinal lumen; and the inference is that local interference with the return of venous blood is one of the primary factors in producing local ileus, as well as in the resulting absorption of toxins. It would follow that the absorption of toxins from retained intestinal contents is negligible until the circulation is so impaired.

Before applying these principles clinically there is one more point I wish to mention. You probably all remember that increase of pressure in a curved metal tube tends to straighten it proportionately to the rise of pressure. Indeed, this principle is utilised in scientific instruments and is easily demonstrable in rubber tubing. Now it is of interest to note that nearly all the hollow viscera are fashioned on the principle of the curved tube, owing to the origin of the mesentery being so much shorter than the attached gut. Intestinal distension results in a proportionate stretching of the mesentery in two directions: (1) longitudinally in the axis of the intestine; (2) at right angles to the gut and towards the origin of the mesentery (see Fig. 1).

FIG. 1.



A–B = Normal loop. A′–B′ = Distended loop. *a–c* and *a′–c′* = Longitudinal tension *a–b* and *a′–b* = Vertical tension.

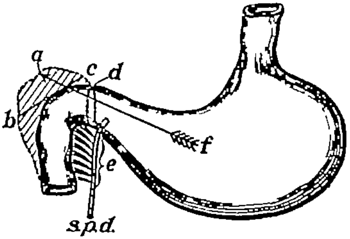
The vertical tension of the mesentery in distension is exemplified by the protrusion of the intestine from the abdomen during laparotomy for obstruction. I have satisfied myself by experiments in the cadaver and in animals that the point is a practical one. Again, the effect of this tension is manifested first in the most collapsible structures—i.e., the *veins*. And the first practical application is the relationship of local ileus and venous stasis to gastro-intestinal ulceration.

CLINICAL ILLUSTRATIONS.

*Gastro-intestinal Ulceration.*—(1) *Stercoral ulcer:* This is one of the late results of distension arising from obstruction. It is significant that venous stasis is always seen in prolonged intestinal distension; and that stercoral ulcers are found at or near the anti-mesenteric border—i.e., in the capillary area most remote from the main vessels. The situation of the ulcer will naturally vary to some extent with the incidence of such factors as trauma, infection, &c., but, on the whole, the situation is fairly constant.

*Chronic Ulceration.*—(2) *Duodenal ulcer:* If we apply general principles to the problem of chronic ulceration in the gastro-intestinal tract, the first point to remember is that one of the greatest enemies to healing is the imperfect removal of waste products owing to an obstructed venous return. I need only mention the familiar varicose ulcer which generally heals quickly when the venous return is assisted by rest and elevation of the limb. Now, unlike the stomach and small intestine, the duodenum is a fixed viscus with no mesentery; therefore straightening of the "curved tube" under increased pressure does not apply to the same extent. On the other hand, distension must clearly affect first the convex border, where the vessels are smallest and most easily obliterated; and this increased pressure will specially affect the most mobile portion—namely, the first part—which becomes the most anæmic. At this point I would remind you that hyperactivity, hypersecretion, and, to some extent, hyperacidity (which are characteristic of duodenal ulcer) are all indicative of the domination of the vagus or motor impulses over the sympathetic.[1] I have elsewhere shown further that the resulting widely patent pylorus, which obtains in duodenal ulcer, favours: (*a*) rapid passage of organisms direct to the first part of the duodenum; (*b*) trauma; and (*c*) distension. All of these are first felt, under these conditions, by the first part of the duodenum.

FIG. 2.—*Duodenal Type of Stomach.*



*a* = Situation of greatest distension. *b–c* = Most anæmic area. *d* = Widely patent pylorus. *e* = Situation of main blood-supply *f* = Projection of pieces of solid food, organisms, &c., direct on most anæmic area. *s.p.d.* = Superior pancreatico-duodenal artery.

If all these points (illustrated in Fig. 2) be borne in mind, it is not difficult to understand the remarkable constancy in situation of the vast majority of duodenal ulcers. Nor is it difficult to appreciate that vagus domination is the essential predisposing factor. Sometimes duodenal ulcer develops consequent on ileus due to compression by the superior mesenteric artery. In such cases Wilkie's operation of duodeno-jejunostomy would appear to be the rational procedure, combined in some instances with ascending colopexy. Macdonald, of Seville, informs me that he has definitely cured duodenal ulcer in such cases by performing Wilkie's operation.

3. *Gastric Ulcer.*—In chronic gastric ulcer an entirely different picture is presented. Here we are dealing with a freely mobile hollow viscus of the "curved type," the distension of which tends to straighten out the concave surface. On this surface the main vessels of the coronary-pyloric blood-supply lie in the gastro-hepatic omentum parallel to the lesser curvature, and, it is to be especially noted, *closely applied to it.* Any straightening of the lesser curvature, under distension, is bound to exert corresponding tension and partial obliteration of the venous return. On the greater curvature it is to be noted that not only are the main vessels (gastro-epiploics) situated a considerable distance from the stomach,

---

[1] Pathology and Symptoms of Duodenal Ulcer, Brit. Med. Jour., June 14th, 1924.

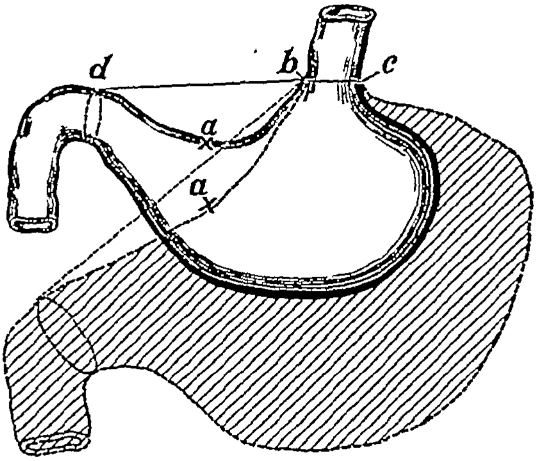
but that, under distension, the anterior part tends to *bulge downwards and forwards in front of these vessels.* There is, therefore, little tendency towards tension on the main veins or obstruction to the venous return.

As a contrast to the former (vagus) type of stomach we are now considering a "sympathetic type." Here the sympathetic impulses dominate the vagus. The pylorus is actively closed and responds sluggishly to the normal mechanism. Intragastric tension is raised and is associated with corresponding obstruction to the venous return over the pyloric and lesser curvature areas. The low acidity common to the "sympathetic" stomach favours infection. If now we add trauma as an exciting factor it is not difficult to appreciate the occurrence, persistence, and recurrence of a chronic ulcer along the lesser curvature, when venous stasis is dependent on persistent or recurrent increase of intragastric tension.

It follows that pyloric closure with the resultant *distension are primary factors in the persistence of* chronic ulcer. The *situation of the ulcer* should be to some extent influenced by the degree of fixity of the pyloric end of the stomach. (*a*) With the very movable pylorus it would be expected that the ulcer would be about the middle of the lesser curvature (Fig. 3, *a*). (*b*) When, however, the pyloric end is relatively fixed, the ulcer will be more liable to form in the areas *a–d* or *a–b*, since there is little venous tension at *a* (Fig. 4).

These expectations are partly based on animal experiments and on observations in the cadaver. And, while it is not possible to be dogmatic, my present impressions are that clinical observation also affords some confirmation. Incidentally it is worth noting how frequently gastro-enterostomy performed for *gastric ulcer* may relieve the symptoms for a time without really curing the ulcer. It is my belief that gastro-enterostomy in such cases achieves its result almost entirely by the relief of intra-gastric tension, and consequent restoration of the venous circulation in the ulcer-bearing area. To some extent also it provides a measure of rest to the stomach proximal to the anastomosis. That the reduction of acidity following gastro-enterostomy influences greatly the healing of ulcers proximal to the pylorus cannot be established on clinical evidence.

FIG. 3.

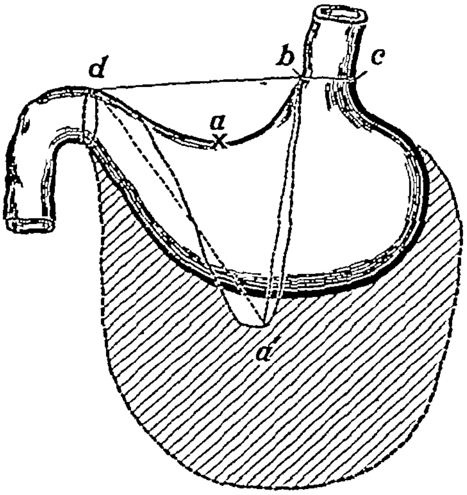


*b–c* = Cardiac sphincter. *a* = Mid-point of lesser curvature. *b–d—b–d* = Contrasted tension on mesentery in empty and distended stomach.

### *Flatulence and Eructation.*

It has already been suggested that under conditions of distension gases may pass from the gut into the blood stream, and that, when venous stasis raises the pressure in the veins above that in the gut, gases will pass in the reverse direction. If this supposition is correct we have at least an explanation of gastric flatulence and eructation arising from a remote lesion. For example, consider the milder mimicry of the acute appendix illustrated by the "so-called" controlling appendix or the Lane's ileal kink. Both of these, by their mechanical irritation of the afferent mesenteric nerves, stimulate a reflex closure of the pylorus synchronously with vagus (motor) stimulation of the proximal stomach.[2] The resulting distension, accentuated by consequent venous stasis, reaches a point when the gastric contractions force the gas into the *œsophagus.*

FIG. 4.



*a–d—a′–d*}
*a–b—a′–b*} = Contrast in mesenteric tension with empty and distended stomach.

You are all familiar with the examination of babies suffering from hypertrophic pyloric stenosis; and you have probably noticed that during gastric contraction the closed pylorus is forced to the right of the abdomen. I have elsewhere pointed out [3] that any closed point of the gastro-intestinal tract causing obstruction to the lumen is treated as a foreign body and driven downwards by the peristaltic waves. The passage downwards is prevented by the mesentery; the tension on which, during contraction, induces pain. Since the stomach itself is devoid of sensation, the tension on the sensitive mesentery during peristalsis is responsible. The same is true of the stomach when the pylorus is reflexly closed. And this is the reason why pain soon after taking food, together with flatulence, may so closely mimic the pain of a gastric ulcer when no ulcer is present.

This raises the interesting point as to the origin of pain in gastric ulcer—a point beyond the limits of this discussion. This much, however, may be said—that *the acute and accentuated pain* in the case of an active (inflamed) ulcer is probably due to the extension of the inflammatory process to the sensitive mesentery. Tension upon an inflamed mesentery, *resulting from* the closure of the pylorus, in such cases, will give rise to greater pain, flatulence, and even vomiting at such time as the activity of the stomach is greatest. Hence the variability of the onset of pain, the intervals of freedom from pain (when the ulcer, though still existent, is not actively inflamed) and the complete relief from pain after vomiting. In my experience vomiting after food, followed by complete relief from pain, is unusual in the absence of an active ulcer or old adhesions. Flatulence and pain after food is common to both conditions. I think we should regard one as a more advanced stage of the other—the mechanism of *the symptoms being similar.*

### VISCEROPTOSIS.

We have now finally to apply these principles to a subject which has been shrouded in much unnecessary mystery. The numerous and varied complaints attributed to visceroptosis, with its known complications (such as "movable kidney" &c.) have led to the existence of two schools. The one condemns these mildly miserable sufferers as incurable, neurotic, &c., and either edges them off to the psychotherapist, treats with vaccines, or recommends a life of constantly recurring rest cures, &c. The other would appear to regard everyone with a prolapsed colon as soil for an infinite variety of energetic surgery.

---

[2] Hunterian Lecture, THE LANCET, 1920, i., 1299, 1315.
[3] Obscure Intestinal Colic, Brit. Med. Jour., Feb. 18th, 1922.

Extreme views in medicine are rarely justified; and if this subject is to be approached impartially there are three undoubted postulates: (1) there are many people with pronounced visceroptosis living perfectly happy healthy lives, and free from complaint; (2) there are *many people suffering from a variety of ailments* who happen to have a prolapsed colon entirely unconnected with their complaints; (3) there are also a considerable number of subjects of visceroptosis in which this is the primary trouble, or, at any rate, plays a considerable part in the symptoms complained of. To take extreme views must obviously lead to error unless we can differentiate accurately these three classes—and here lies the difficulty and the origin of failure and discredit.

Full discussion of so wide a subject is clearly not within the scope of this paper, but, in order to render the survey more complete, I am anxious to suggest to you the principles which should guide us. The first important principle to be borne in mind is the importance of the mesentery, with its contents so vital to the life and health of the individual. It is clear that such a structure can never be, and never was intended to be, a supporting structure for the viscera.

In the adaptation to the erect posture *two main mechanisms of visceral support* have developed; and *the function of both is to protect* the delicate mesenteric contents from mechanical strain. These are:—

(*a*) *Certain fixed points* for attachment of the viscera. These are well-known anatomical facts which are familiar to you and require no elaboration. Together with these fixed points are certain whole lengths of intestinal tract which become more or less "fixed" by a normal fusion of the primitive mesentery—e.g., duodenum, ascending and descending colon. These two purely mechanical methods of adaptation to the erect posture show great variability in different individuals. This variability is sufficiently marked to suggest that the complete adaptation of the viscera to the upright position is in a transitional stage of evolution. It would follow that excessive mobility is to be regarded as incomplete development; while the presence of abnormal bands, or so-called "kinks," may in some instances be regarded as over-development of the normal process of fixation. Both defects can originate pathological processes.

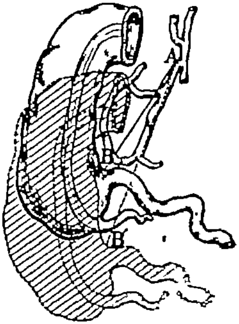
(*b*) *Intra-abdominal Pressure.*—The support afforded the viscera by normal pressure is a factor which varies with different conditions of posture, exertion, &c.; and it is self-regulating under normal conditions. Thus, when the erect posture is assumed the abdominal muscles automatically contract and afford the necessary support to the viscera. This takes place in the following way: On standing up the viscera tend to fall toward the pelvis and the mesentery gets *dragged* upon. The resulting mechanical tension stimulates the Pacinian corpuscles (sensitive organs of "touch"), from which proceed afferent impulses exciting the efferent response along the somatic nerves to the abdominal muscles. The resulting contraction of these saves the mesentery from further tension by increasing the intra-abdominal pressure and supporting the viscera. The hernial rings are closed by a similar mechanism. The Pacinian corpuscles, together with the reflexes they initiate, are to be regarded as normal means of protection of the mesentery against mechanical tension in the erect posture. The importance to each individual of the integrity of this "*musculo-mesenteric*" reflex will obviously vary with the degree of purely mechanical support—i.e., degree of fixation—afforded in any given instance, and this varies widely.

The study of visceroptosis, then, is to be divided into two groups: (*a*) results of the breakdown of the normal visceral supports, and (*b*) factors favouring such a breakdown.

(*a*) The mesentery assumes the function of visceral support and the resulting tension on nerves (afferent and efferent), blood-vessels, and lymphatics is responsible for symptoms which are often far-reaching and progressive.

*Nerves.*—These run in company with the blood-vessels and lymphatics, and, like the latter, when there is a minimum of fat and areolar tissue in the mesentery, become themselves responsible for visceral support. As we have seen in the case of inflammation, so also in mechanical stimulation, both efferent and afferent impulses arise. Direct stimulation of the efferent sympathetic inhibits the bowel and leads to stasis over the area involved; while the consequent overloading of the bowel adds to the mesenteric burden and further increases the tension. The result of the afferent stimuli is a generalised efferent sympathetic response of varying degree, leading to such remote results as general inhibition of the whole intestinal tract (especially the colon),[4] pyloric closure with consequent increase of gastric distension, inhibition of the gall-bladder with stagnation of bile and a consequent *predisposition to gall-stone formation*, &c.

FIG. 5.



In support of these views may be mentioned the regularity with which general visceroptosis is found in the subjects of gastric ulcer. This is in sharp contrast with the *majority of* duodenal ulcers. Also, in the absence of primary disease of the gall-bladder itself as a cause of gall-stones, the existence of these is practically always associated with general visceroptosis. Further, typical gall-bladder attacks (in the absence of stones) due to over-distension of the gall-bladder are exceedingly common in sufferers from visceroptosis.

Fig. 5 shows how it is that the results of *mesenteric tension* are first felt in the [illegible]-ascending colon region. Here the tension is [illegible] in the long axis of the main vessels to the [illegible] that the associated nerves very early feel the strain (*A–B—A–B*). In this region, too, we have [illegible] that the vagus will share in the general [illegible]. The result is (as we have seen in [illegible] appendicitis) that the efferent vagus [illegible] will tend to excite hyperactivity of the [illegible] secretion, patent pylorus, &c. The [illegible] only to find some factor which [illegible] sympathetic stimuli—e.g., tobacco [illegible] to appreciate how mesenteric tension (or [illegible]) in the vagus area—i.e., the [illegible] and [illegible] transverse colon—may [illegible] of vagus over sympathetic [illegible] establish a predisposition to du[illegible]. This [illegible] contrast with the sympathetic [illegible] associated with *general* visceroptosis [illegible] the necessary exciting conditions, [illegible] likely to be gastric.

*Veins.*—T[illegible] must of necessity tend to diminish [illegible] the venous [illegible] more difficult [illegible] the smaller [illegible] of the gut. Here we have an all-important factor in causing the distension and constipation associated with visceroptosis, since the necessary muscular contractions are impaired in the presence of continued venous stasis. This again is particularly marked on the right side (Fig. 5) for reasons already given. And I would emphasise this point—namely, that venous congestion arising from mesenteric tension in the upright posture is accentuated by the fact that *veins of the portal system are devoid of valves.*

---

[4] [illegible] 1925 [illegible]
[5] Path[illegible] of England [illegible]
Jour., [illegible]

In support of this view, that there is a variable measure of intestinal venous stasis in sufferers from visceroptosis, it is noticeable that, where symptoms are pronounced or long standing, the small arteries in the ileocæcal region will frequently be found abnormally elongated and tortuous.

*Arteries.*—It is unlikely that any mechanical interference with the arterial supply can result directly from traction on the mesentery, but reflex vasoconstriction, arising from the generalised sympathetic stimulus, may play a part in the defective circulation of the gut.

*Lymphatics.*—Much that has been said in the case of the mesenteric veins may apply with equal importance to the lymph stream. For interference with absorption may partly account for the wasting so commonly seen in this class of case. Further, the consequent loss of fat within the mesentery accentuates the liability to mechanical interference with these vital structures under increased tension.

Finally, it is evident that the overloading of the bowel arising from inhibited muscular action tends of itself to increase mesenteric tension; and this again must aggravate the muscular failure. The bowel then becomes progressively distended and thinned—a characteristic feature. Where right-sided aching or dragging pain, relieved by rest, is *the only symptom* complained of, it will frequently be found that adventitious adhesions or bands anchor the bowel to the sensitive lateral peritoneal wall. The mesentery is thus spared, but pain results in the erect posture. It is evident, therefore, from a consideration of the pathology, that where symptoms arise from visceroptosis the condition is bound to become progressive, unless adequate treatment is adopted on lines directed towards the protection of the mesentery.

(*b*) *Reasons for the Breakdown of the Mechanism of Visceral Support.*—The primary factor is the absence of the mechanical supports already mentioned; and these have been stated to be congenital and atavistic. Under these conditions—i.e., congenital mobility of the colon—the compensatory reflex (which is almost entirely responsible for visceral support) may break down from several causes, some of which may be mentioned. Commonest among these are: (1) diminution of intra-abdominal pressure, and (2) overloading of the colon.

(1) This may occur in a variety of ways:—

(*a*) *Puberty.*—The widening of the pelvis occurring at this time is sometimes associated with the onset of aching on the right side, or by intermittent attacks of pain often accentuated just before the menstrual period. Clearly the increased pelvic accommodation will favour visceral descent, while the hyperæmia, so pronounced at this time, accentuates the liability to vascular engorgement. In sufferers from visceroptosis it is exceedingly common to find the symptoms aggravated just before the period and relieved after the onset. Further, the relief of pain in the horizontal posture is characteristic.

(*b*) *Childbirth.*—Here the widening of the pelvis, together with the impairment of the abdominal and pelvic muscles, still further interferes with visceral support and causes mesenteric tension. As we have seen, this is most commonly shown at first in the right-sided drag, so commonly complained of. Reflex effects on the intestinal tract, stomach, and gall-bladder follow later; and frequently all are accentuated at the time of the period. Frequency of micturition in the day and its absence during recumbency at night are a later indication of the descent of the kidney with venous congestion consequent on the tension on its pedicle. The onset of symptoms dating from childbirth is exceedingly common, and clearly demands attention to the abdominal and pelvic muscles as a means of restoring efficient visceral support. But when symptoms arise at or soon after puberty and the abdominal and pelvic muscles are faultless, my experience has been that symptoms almost invariably recur and are progressive. In such cases an efficient right-sided colopexy is invariably successful. It will also be required in about 60 per cent. of the second class.

If these principles are accepted it will be found that a great many valueless appendicectomies may be avoided.

(*c*) *Defective Muscular Nutrition.*—Occupations involving deficient oxygenation, chronic toxæmia from any cause, particularly when associated with constant standing, are often associated with a failure of the whole muscular system, including the abdominal and pelvic musculature.

(*d*) *Standing occupations* are often responsible for the onset of symptoms. You all know that any reflex will break down under fatigue; and it is only rational to recognise that the "musculo-mesenteric reflex" should fail under insufficient rest.

(2) *Overloading of the Colon.*—This may well initiate mesenteric tension (when fixed support is defective) and, as you know, it may arise from a variety of causes. Prominent among these are habit (commonly started in childhood); dyschezia (which I believe to be anatomical in most instances),[6] mental, improper food,[7] in some instances a gross lesion—i.e., appendix, tubes, &c. Causes are legion and I only give examples.

In conclusion, may I say that I have not attempted to deal in detail with any of the disorders mentioned because my object has been an attempt to present to you the principles involved, and to emphasise the fact that in the health of the gastro-intestinal tract (and in the symptoms of disease of that tract) the mesentery is the first consideration. This is not generally accepted in the treatment of visceroptosis; but I would ask you to give this particular question your close consideration. And, while you will appreciate that any detailed criticism of the various forms of treatment (exercises, correct breathing as advocated by McMahon,[8] indications of operation, &c.) are beyond the scope of this discussion, some general deductions are justified.

### *CONCLUSIONS.*

A great part of abdominal surgery should be directed towards the protection from damage of so vital a structure as the mesentery, whether by infection or mechanical trauma. In the latter instance a large group of disorders arise primarily from visceroptosis, whether local or general. Treatment in such cases should always be directed towards protection of the mesentery from undue strain. Sometimes this can be done by conservative measures; sometimes these can achieve no permanent improvement. And in some instances this can only be achieved by the surgical remedy of the defective mechanical visceral support.

The indications for surgical interference are a debatable question of sufficient importance to form a subject of itself. But this much may be said in conclusion. I have practised the operation of colopexy in different forms and degrees for about 18 years, in many hundreds of cases with an increasing degree of success. This is due to more accurate selection of cases with increased experience. I am quite convinced that a rejection of this simple and safe surgical measure is due either to a failure in technique, to a failure to realise the principles upon which the selection of cases should be based, or, more often, to neglect of efficient after-treatment.

INSTITUTE OF HYGIENE.—The President, Sir Thomas Oliver, will receive the guests at a reception to be held at 28, *Portland-place, London, W., on* Thursday, Feb. 25th, at 8.45 P.M. The museum, which contains many exhibits of interest, will be on view, and there will be a special display of scientific apparatus and a practical cooking demonstration.

# FOCAL SEPSIS AS A FACTOR IN DISEASE.

*Being the Opening Paper at a Discussion at the Royal Society of Medicine on Feb 15th, 1926,*

BY GEORGE R. MURRAY, M.D. CAMB,
F R C.P. LOND.,
EMERITUS PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY OF MANCHESTER, CONSULTING PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE, AND TO THE MANCHESTER ROYAL INFIRMARY.

DURING recent years much attention has been drawn to focal sepsis, and we have learned how important a part it may play in the causation of disease and in the progress of a malady already present In order that we may, as far as possible, have a definite idea of what we are discussing, I propose to outline the various ways in which focal sepsis may become a factor in disease These will be illustrated by a few brief clinical sketches of personal experiences, in most of which, owing to the circumstances under which they occurred, no bacteriological examination was made.

A malady may be initiated, or its course affected, by a local infection in several different ways. First, the bacteria causing the focal infection may be discharged and conveyed by mechanical means, so as to cause extension of the disease by reinoculation. Second, the bacteria present in the original focus may overcome the local resistance and be conveyed to distant parts of the body by way of the lymphatics and the blood. Once the bacteria leave the original focus either singly or in clumps, they may be arrested by the nearest lymphatic gland and set up a lymphadenitis which may develop into an abscess. If the infection passes this barrier, three things may happen · (a) If the organisms are virulent, they may multiply in the blood and set up either an acute or chronic septicæmia. (b) If the bacteria do not multiply in the blood they may be conveyed alive to a suitable nidus where they multiply and infect the surrounding tissues. (c) If the bacteria conveyed by the blood are unable to gain a real footing anywhere, they may, by the process named subinfection by J. G Adami,[1] produce a slow but progressive atrophy with replacement fibrosis in various organs of the body. Third, the micro-organisms may remain enclosed at the seat of focal infection from which their toxins are slowly and continuously absorbed so as to cause either temporary alteration in the structure and function of the blood and other tissues or possibly permanent structural changes, such as fibrosis, in important organs.

### *Mechanical Conveyance of Infection.*

A few practical illustrations of the influence of focal sepsis will be given under the headings just mentioned. The results of the mechanical conveyance of infection are seen, in a simple form, in a case of furunculosis, in which the staphylococci are conveyed by the fingers or by the clothing from the primary boil to other parts of the skin, where reinfection takes place In open oral sepsis, due either to the decomposition of food particles or tartar deposited in the gingival trough, or to pyorrhœa resulting from chronic periodontitis, bacteria are constantly brought into contact with the tongue and pharynx, and may set up superficial glossitis or pharyngitis Infection is occasionally conveyed up Stenson's duct to the parotid gland Thus I have seen a man who was laid up with a unilateral parotitis, which persisted until it was realised that it was due to an ascending infection from a septic molar tooth situated near the opening of Stenson's duct As soon as the tooth was removed the parotid gland recovered

In both oral and nasopharyngeal sepsis many bacteria are swallowed. In a normal stomach they are usually destroyed by the gastric juice. In a small proportion of cases the resistance of the stomach is impaired and a chronic gastritis or gastric ulcer develops. A man of 58 gradually lost his appetite, the weight decreased by 3 st., and there was vomiting. When I saw him he was lying in bed, weak and emaciated, and the skin of the face and neck was pigmented, so that the symptoms were suggestive of malignant disease of the stomach. Physical examination yielded no sign of abdominal or thoracic disease, but revealed marked oral sepsis. A diagnosis of septic gastritis was made and proved to be correct, as treatment by the immediate use of an antiseptic mouthwash, removal of the teeth, and the internal administration of manganese dioxide was followed by complete recovery in the course of a few months

The infection arising from oral sepsis may pass through the stomach and cause infection of either small or large intestine A boy, who was seen some years ago, was in poor general health owing to severe oral sepsis. The relations were advised to have the teeth removed at once and were warned of the danger of delay. Unfortunately, extraction of the teeth was refused, and a few months later the boy developed severe ulcerative colitis and died. A septic gall-bladder, by discharging bacteria along the common bile-duct, may infect the bowel lower down. In the case of infection of the gall-bladder by the typhoid bacillus, the host becomes either a temporary or chronic "carrier," and so a source of infection which may set up typhoid fever in others The long duration of this focal infection in some cases is illustrated by the records of "carriers," mentioned by Prof Topley,[2] who have continued to infect the healthy for as long as 25 years. An infected but still patent appendix may cause ill-health by continually discharging its contents into the cæcum. Sir Rickman Godlee,[3] in one of the earliest papers dealing with this subject, recorded such a case in which the chief symptoms were pallor, loss of appetite, loss of weight, slight fever, and the passage of offensive motions. Complete recovery followed the removal of the diseased appendix.

Infection from the mouth may pass directly, not only to the alimentary canal, but to the respiratory organs A woman, on account of dental sepsis, had several teeth extracted while under general anæsthesia. During, or just after the operation, she unfortunately inhaled either some inspissated pus, or possibly a small fragment of an infected tooth, into a bronchus. This set up an acute local infection of the lung which, by the time I saw her, had become gangrenous and shortly afterwards proved fatal.

### *Transference of Infecting Organisms by the Blood.*

When bacteria which at first were confined to a local area find their way into the blood, a general septicæmia may result. This sequence of events has occurred only too frequently in those tragic cases in which a surgeon during an operation, or a pathologist while making an autopsy, has received a slight wound which has become infected, and the infection, spreading later to the blood, has caused a fatal septicæmia. Micro-organisms which gain access to the blood may be unable to multiply until they reach some tissue for which they have a selective affinity, and in which they can multiply sufficiently to set up a definite lesion A healthy young farmer, in the course of a quarrel, received a wound in the forehead from a tumbler which was thrown at him The wound was dressed once by a surgeon. He returned to his work on the farm, but took no further care of the wound. This became infected, probably by his hands while at work, cellulitis of the neck followed, and finally acute malignant endocarditis ended a promising career

In closed oral sepsis, such as occurs when an abscess forms at the root of a tooth, streptococci may be forced into the general circulation by the intermittent pressure exerted on the tooth during mastication. Under these circumstances the streptococci are liable to be lodged in the joints or periarticular structures. When we are confronted by an arthritis or other malady which may be caused by secondary infection from some occult focus of sepsis and in which the mouth looks harmless, let us not "forget the poisonous dregs that lurk beneath," but insist on an X ray examination of the gums. A middle-aged man, who for some time had resided in another country, consulted me on account of an early arthritis which had already involved several joints. He assured me that his teeth had been well looked after and were in good condition. On inspection the gums looked healthy, but many of the teeth were crowned with gold. An X ray examination revealed the presence of abscesses at the roots of several teeth. Removal of the affected teeth was at once followed by rapid improvement in the arthritis.

Sir William Willcox [4] has shown the frequent relationship between oral sepsis and arthritis, and agrees with Dr. A. P. Beddard that 90 per cent. of cases of rheumatoid arthritis in man are due to this cause. Rosenow [5] has shown that muscular fibrositis may be caused by the lodgment of streptococci of low virulence in the capillaries near the tendinous insertions of the affected muscles. This is apt to occur when the original focal sepsis is due to the *Streptococcus viridans* and other non-hæmolytic strains, the actual lesion in the muscle being due to subinfection. The relationship between oral sepsis and severe secondary and pernicious anæmias has been shown by Dr. William Hunter[6] to be of frequent occurrence. Focal sepsis is, however, not the only cause of these conditions, as pernicious anæmia develops in persons who have been toothless for years and in whom no septic focus can be found. In connexion with the affinity of streptococci for the joints and periarticular structures, the work of Rosenow may again be referred to. He showed that streptococci cultivated from a septic focus in man had an elective affinity for the same tissue in a healthy animal as that from which they had been taken. Thus, streptococci taken from a cholecystitis were, on inoculation, much more likely to reproduce the same condition than any other lesion. He also found some evidence in favour of the view that the toxins produced by the streptococci may have a similar selective action on the tissues. Rosenow suggests that this selective action may depend on the amount of oxygen and food-supply available in different parts of the body as each strain of streptococci has its own special requirements. This peculiarity may be one of the factors which, fortunately, enable many persons to resist secondary infections and the ill-effects of toxæmia altogether, or, at any rate, for long periods. This resistance, in the case of oral sepsis, for example, may partly be due to a tolerance acquired by the long-continued presence of large numbers of streptococci in the mouth and in the bowel of normal individuals.

Sir Frederick Andrewes [7] has drawn attention to Dr. Gordon's examination of the buccal secretions which, in healthy human beings, were found to contain from 10 to 100 million streptococci to the cubic centimetre. In the bowel, where the *Bacillus coli* group and streptococci predominate, Houston has found the latter may exceed the former and be present to the number of 1000 million per gramme of the fæces. When we recollect that one-quarter of the fæces consists of bacteria, a large proportion of which are dead by the time they are voided, we can realise how great is the natural resistance to such inhabitants as long as they are outside the tissues. When ill-effects occur they are due to the virulence and numbers of bacteria which cause the development of focal sepsis, or to a lowering of the resistance of the host, or to a combination of both factors.

The joints are not the only structures liable to suffer from metastatic infection from the gum or the tonsil. During an epidemic of streptococcal tonsillitis in a Lancashire town I saw a young man suffering from acute nephritis which had followed an attack of tonsillitis. Streptococci were present in the urine, so that the nephritis was evidently secondary to the focal sepsis in the tonsil. This epidemic affected a considerable number of people but, as far as I could ascertain, nephritis was quite an exceptional complication. Not only may metastatic infection originate from a septic focus, but it may continue to be active as long as the primary focus is allowed to remain. In these cases it seems probable that the secondary infections are being continually reinforced or renewed from the primary focus. A striking example of this persistent effect of focal sepsis in a case of rheumatism has been communicated to me by Dr. C. P. Lapage, who will publish full details. A boy, aged 10, continued to suffer from recurrent attacks of rheumatism with sore-throat, fever, severe mitral endocarditis, and unusually large subcutaneous nodules. Treatment by rest, salicylates, and change of climate failed, and so, finally, the tonsils were removed. After this there was no recurrence of sore-throat, the nodules disappeared, and cardiac compensation developed so well that he was able to go to school five years after the first illness. It is important to remember that if the focal sepsis remains undetected and unrelieved it may continue to exert its evil influence on health over long periods. Godlee described a case in which several sequestra, which were ultimately discovered in the femur, had caused recurrent abscesses at intervals for 40 years.

### *Absorption of Toxins from a Septic Focus.*

So far, the relationship between focal sepsis and the disease attributed to it is fairly clear. This relationship is more difficult to prove when there is no actual metastatic infection, but the morbid process is due to the action either of exotoxins formed locally and conveyed to other parts of the body, or of endotoxins liberated in cases of subinfection during the dissolution of the bacteria lodged in the tissues. In many cases it is not possible to distinguish between these two processes. One form of disease, amyloidosis, affords an example of definite tissue changes resulting from the continued absorption of toxins from a septic focus. A boy, whom I saw with a country practitioner long since deceased, had an empyema unrecognised until it began to leak through a small orifice just below the left nipple. The only treatment which had been attempted was the insertion into the sinus of a piece of the fine rubber tubing commonly used in association with Southey's tubes, which only allowed the pus to escape in drops. The liver and spleen were greatly enlarged owing to amyloid infiltration. Efficient drainage of the empyema was followed by recovery, and, though I did not see the boy again, I was informed that ultimately the enlargement of both liver and spleen disappeared. Godlee [8] recorded a similar case in which a small but imperfectly drained empyema caused lardaceous disease of the liver and kidneys, with marked clubbing of the fingers. Free drainage led to the closure of the empyema, and this was followed by disappearance of the clubbing of the fingers and of the lardaceous disease, except for an occasional slight albuminuria. In another of his cases, a patient with long-standing empyema had refused operation and pulmonary osteo-arthropathy developed. This condition disappeared after the empyema had ruptured and discharged through a bronchus. Chronic ill-health or severe and acute illness may be due to the absorption of toxins from an unsuspected source, and Godlee showed the importance of hidden drops of pus: "the unseen pus that walketh in darkness and wasteth at noonday."

It is remarkable that even a large septic focus may be the unsuspected source of an illness. This was well illustrated by the case of a man who was acutely ill with a high and irregular temperature and other indications of a severe toxæmia for which no cause had been found. He had a cystic goitre which had been present for a long time, but had caused no special inconvenience. On examining this patient I found that the goitre yielded a resonant note on percussion, and suggested that this curious sign was due to infection of the cyst by the *Bacillus coli*, which is a gas-forming organism, and that this local infection was the cause of the toxæmia. I know it may be objected that there is as yet no definite proof that the *B. coli* produces exotoxins. It should, however, be remembered that the existence of streptococcal exotoxins has only been recently proved. When the cyst was opened it was found to contain gas and pus which gave the characteristic smell which indicates the presence of the colon bacillus. No bacteriological examination was made, so that there may have been a mixed infection, but the rapid recovery which followed drainage of the cyst clearly indicated the relationship of the infected cyst to the illness. In cases of oral sepsis the disappearance of anæmia, lassitude, and other signs of toxæmia on the removal of septic teeth, before the insertion of artificial dentures, is regarded as sufficient evidence that the ill-health was due to sepsis and not to dental deficiency.

While mentioning the beneficial results which usually follow the removal of a septic focus, it may be pointed out that there may be more than one focus, and also that focal sepsis may not be the only cause of the symptoms in any particular case, so that other foci and conditions must be looked for if the expected improvement does not follow the removal of a septic focus. The treatment of a septic focus is not altogether free from danger. An acute temporary exacerbation of the symptoms frequently follows the removal of septic teeth, owing to the absorption of an extra dose of bacteria and their toxins during the operation. Occasionally this has been followed by hæmic infection and fatal septicæmia. Godlee mentions cases where the opening of an abscess, which up to the time of the operation had caused no serious disturbance of health, was followed by a fatal result.

We know very little of the effect of focal sepsis on the pregnant woman and the unborn child. The results of dental sepsis in the nursing mother and her child have been described by H. Waller.[8] He shows that the secretion of milk may be diminished by one-half, so that the child's weight remains stationary or increases very slowly. In addition, the child shows dislike of the milk and is sick. After removal of the teeth, lactation increases and the child flourishes. This ill-effect is apparently exerted by toxins secreted in the milk, as bacteriological examination of the milk was negative. Waller found that this wasting and vomiting in breast-fed children was due to oral sepsis in the mother in 160 out of 200 cases.

The relationship between focal infection and diseases of the skin, which has been recently reviewed by Dr. H. Leslie Roberts,[9] cannot be dealt with here, nor can the relationship of sepsis to certain forms of glycosuria.

The endocrine glands are not very susceptible to the influence of focal sepsis. In the course of acute rheumatism the thyroid gland may be enlarged and tender. I have seen exophthalmic goitre develop directly after an attack of acute rheumatism, before the patient left the hospital, but this sequence is rare. H. Vincent has, however, observed both exophthalmic goitre and myxœdema as sequels of acute rheumatism. Billings[10] has observed cases of exophthalmic goitre with dental or tonsillar sepsis which rapidly improved on removal of the sepsis. I have seen very few cases of disease of the thyroid gland in which focal sepsis could be regarded as the cause of the malady. In only two of a series of 300 private cases of exophthalmic goitre was such a focus found.[11] In cases of hyperthyroidism and exophthalmic goitre focal sepsis may aggravate the condition or retard recovery. Marked improvement follows removal of sepsis in these cases, but the symptoms do not disappear, as one would expect if the sepsis had been the prime cause of the thyroidal disease. The pituitary and suprarenal gland are even less susceptible. Acute pancreatitis may follow oral sepsis, possibly by way of an ascending infection from the bowel.

In the present discussion it would carry us too far afield to consider the influence of what may be called systemic, rather than focal, infection in disease, though the modes of exerting such influence are similar to those we are considering. Under the heading of systemic sepsis may be included infections of the bronchi, bile passages, and genito-urinary organs which may lead to distant lesions such as gonorrhœal rheumatism. For the same reason the results of the absorption of toxins from the alimentary canal in cases of intestinal stasis is beyond the scope of the present discussion. I should like, however, to mention in passing that, as far as my own experience goes, the latter condition is much less frequently a cause of disease than has been stated by some writers. In fact, excluding examples of gross organic disease or malformation, I cannot recall a case in which excision of any portion of the bowel was necessary in order to remove a possible source of toxæmia.

### *Summary.*

The present situation may be briefly summarised by stating that the most frequent sites of focal infection are to be found in the head, in the diverticula of the alimentary canal, and in the genito-urinary organs. The bacteria commonly concerned in these infections are nearly all micrococci; streptococci of various strains, staphylococci, pneumococci, and gonococci. To these may be added the colon bacillus and other members of the same group, and on occasion various other bacteria may play a part. The maladies which are most likely to result by the direct mechanical conveyance of bacteria from a focal sepsis are infections of the skin, alimentary canal, and respiratory passages. Hæmic infection or subinfection and toxins conveyed by the blood may cause septicæmia, malignant endocarditis, secondary and pernicious anæmia, acute and chronic arthritis, neuritis, fibrositis, certain diseases of the skin, and occasionally inflammation of either secretory, incretory, or excretory glands.

# THE TREATMENT OF RODENT ULCER

## (BASAL CELL EPITHELIOMA), WITH ESPECIAL REFERENCE TO RECURRENCE.

BY F. HERNAMAN-JOHNSON, M.D. ABERD.,
RADIOLOGIST TO THE FRENCH HOSPITAL, LONDON; PHYSICIAN IN CHARGE, X RAY AND ACTINOTHERAPEUTIC DEPARTMENT, CROYDON GENERAL HOSPITAL.

THE term "rodent ulcer" has become established in this country by long usage, but it is essentially a bad one. It tends to distract attention from the real nature of the condition which it purports to describe. The problem of cure is presented as one concerned with the healing of an ulcer, instead of the eradication of a malignant neoplasm.

The rodent is usually, but not always, a horizontally extended tumour—originating in the sebaceous glands, sweat glands, or hair follicles—which tends at a comparatively early stage to surface necrosis. Occasionally, however, a definite tumour appears. This takes the form of a small flattened lump, projecting perhaps an eighth of an inch above skin level. It is covered by normal epithelium, and may progress slowly for months or years without ulceration. In this type it is obvious what we are dealing with—it is a basal cell epithelioma pure and simple; but we should learn to regard all rodents equally as genuine new growths. Despite the fact that basal cell epithelioma does not tend to metastasise, and that its progress for a long time may be slow, it does recur with much persistence; and no one who has watched the terminal stages of an unsuccessfully treated case can doubt that it is, in the full sense of the word, malignant.

Up to the end of the nineteenth century there were practically only two ways of treating rodents—by surgical excision and by caustics. Since then it has become possible to cause the disappearance of these growths by a number of methods—X rays, radium, carbon dioxide snow, "ionisation," and the diathermic cautery. Cosmetic results have been greatly improved, but, despite this wide choice of means, the percentage of recurrences, so far as can be ascertained, is substantially unaltered.

### *X Ray Applications.*

The remarkable manner in which basal cell epithelioma melted away under X ray applications led the early workers to believe that an almost magical cure had been discovered. Within a year or two, however, recurrences were reported. At this time it was held that X rays killed malignant cells while damaging to a less degree the normal tissues. This is the doctrine of selective lethal action, which has been responsible for both good and evil in the history of radiotherapeutics. Looked at from the point of view of this theory, recurrence was regarded as evidence of insufficient initial dosing. For some time it was not possible greatly to increase the dose, as the soft unfiltered rays then in use soon caused irritation if pushed. Presently came the aluminium filter, and apparatus was built to give hard rays. Optimistic predictions were made to the effect that rodent ulcer would now really be cured, as it had become practicable not only to give much heavier doses, but to attain approximately equal irradiation of all cells to a depth of several millimeters.

Nevertheless, the recurrence rate continued much as before. Treatment up to this point had been by divided doses. In 1911 J. F. Gaskell published some researches on the effect of X rays upon chick embryos, in which he showed that, in order permanently to stop development, a certain minimum quantity, which he called the "critical dose," must be administered. This varied according to the degree of metabolic activity, and any lesser dose, or division of the critical dose, was without effect. I suggested, in a paper read before the Radiology Section of the British Medical Association at Liverpool in 1913, that the principle of the critical dose might be applicable to the treatment of rodent ulcer; and, in the brief time before the reading of this paper and the outbreak of war, I endeavoured to put into practice the "critical dose" in the treatment of basal cell epithelioma.

I found that a concentration of dosage produced a smart reaction, followed by rapid healing. The war intervened, and attempts to trace cases in 1919 were only partially successful. So far as they went they showed that recurrences had occurred in several instances. Clinical experience since then has led me to believe that, while concentration of dosage gives good results in many cases and is a convenient method, it affords no guarantee against return.

### *Radium Treatment.*

Radium treatment has gone through much the same phases—first, the prolonged application of small quantities of unscreened radium; later, short treatments by large quantities heavily filtered. Here, again, no panacea against recurrence has been found. Not only do recurrences occur with any form of radiation treatment, but, as a rule, they yield slowly, if at all, to further application of the same type of radiation. On the other hand, a method which is, in essence, stimulative, as with so-called ionisation with zinc, may effect a cure. These facts have been obvious for many years, yet some writers continue to preach the doctrine of the lethal dose. It was revived and preached with the fervour of a *Jehad* by the Erlangen School in 1921, but is now falling into disfavour even in the country whence it was so fiercely promulgated. I myself realised, even when advocating an attempt to find a "critical dose," that stimulation of the normal tissues counted for a good deal in any "cure" of cancer by X rays. That such rays have a directly depressant action upon malignant cells is certain; but the more I see of radiotherapy in cancer, the more am I inclined to stress the importance of stimulation of the normal tissues as the chief factor in any non-surgical cure. An appreciation of the fact that the cause of the disappearance of a basal cell epithelioma under radiation treatment is in the main due to an excitation of normal defence mechanisms makes clear the futility of attempting to give "lethal doses," and points the way to the proper treatment of recurrent growths.

It appears to be a physiological law that living cells eventually become "stale" to the frequent repetition of a given stimulus. It is also true that cells in this condition of staleness may nevertheless respond quite well to an excitant of a somewhat different nature. What I may call the *principle of the varied stimulus* is a most important one in medicine, and its application in the case of recurrent rodent ulcer is productive of excellent results. Neglect of it, on the other hand, leads to disaster. I regret to say that even now one frequently comes across cases in which, in the face of the most definite failure of response, X rays or radium have been persisted in for months—with the result that the capacity to react to any stimulus has sometimes been destroyed. I am fully aware that recurrences may respond to the same agent which originally succeeded; but if the response is going to be satisfactory the fact is evident within a few weeks. Persistence beyond a very short period is, in my experience, a grave error of judgment. In non-malignant cases, such as lupus, obstinacy and ignorance disguised as perseverance may actually cause the lesion to become cancerous, and thus discredit is cast upon X ray therapy in general.

### *Resensitisation.*

X rays and radium have such advantages over other forms of treatment as regards cosmetic result and painlessness of application that there is a great temptation to try them again in case of a recurrence. The patient, also, is generally anxious to have again what he found so successful upon the first occasion. To yield to these seductions is harmless, provided a strict time limit is observed. But what is to be done if, at the end of a month, there is no improvement —or if the condition, having responded for a time, ceases to progress favourably? It is of vital importance to recognise that the tissues must be treated by a different stimulus, or "resensitised" to the original stimulus before any further progress can be made.

*Change of Stimulus.*—A rodent ulcer which has ceased to respond to hard X rays or to the gamma rays of radium may sometimes be started off again in the right direction by rays of widely differing frequencies—e.g., by soft X rays, or even by ultra-violet rays. Instead of changing the stimulus, we may discontinue the radiation treatment for a time, meanwhile seeking by some means to resensitise the tissue cells—i.e., so to alter them that they become again capable of responding to the original radiation.

*Resensitisation.*—One of the best means of restoring response is surgical scraping, carried to a point where free bleeding results. It would appear as if prolonged raying used up certain essential substances in the tissues; but that a fresh blood-supply restores these constituents and enables further response to take place. If curettage is done, it is very important to begin X rays immediately upon the raw surface, and to clean the wound every day from sloughs or coatings of congealed pus. Treatment should be by small doses three times a week until healing has occurred. The scraping should extend well beyond the actual ulcer, any raised edges being levelled.

Surgical curettage is suitable only in the case of small rodents in situations where a local anæsthetic is alone required. In selected cases freezing with carbon dioxide snow serves the double purpose of producing a fleeting loss of sensation—which, however, lasts long enough for the curette to be used—and producing a smart reaction which in itself is helpful. If a general anæsthetic is necessary, it is much better to use the diathermic cautery. To this I shall refer later.

An alternative method of resensitisation is to "ionise" with zinc or copper. It is held by some that there is a relationship between potassium starvation in the cells and malignant multiplication; and to add some potassium salt to the solution, for use under the positive pole, can at least do no harm. Interest in the effect of secondary X radiations from metals first led me to try this procedure in the year 1912. The ulcer was ionised with a view to depositing in it fine particles of zinc or copper, which were to *act as sources of secondary radiation* when excited by an X ray tube. They were supposed to give rise to *pandrastic* rays within the tumour—i.e., to rays issuing in all directions from numerous points. Subsequent investigation has cast doubt upon this theory, but there is no question but that the practical results are often brilliant. It now appears to me probable that the galvanic current itself in some way restores the power of the normal cells to respond to radiation—perhaps, in part at least, by provoking an inflammatory reaction When ionisation plus X rays succeeds, the cosmetic results are all that can be desired.

### *Diathermic Cauterisation.*

The treatment thus indicated of recurrences by radiation, even when procedures aiming at resensitisation are carried out, should not, in my opinion, be tried for more than two months. The ultimate resort is destruction by the diathermic cautery. This always necessitates a general anæsthetic. Ether may be used provided that the bottles, &c, are removed to a safe distance during the actual progress of the operation.

The method used should be thermo-coagulation, and not fulguration or sparking. I am personally in the habit of placing the cautery in position before the current is turned on. The resistance should be placed at its maximum—i e, the current at its weakest—and the lever very cautiously advanced Unless working with an apparatus with which one is very familiar, it is desirable to test first upon a piece of meat, and to mark a place upon the resistance beyond which the assistant must in *no circumstances* move the lever. The capacity to decide rightly how much to do in a given case can be acquired only by experience Personally, I have no hesitation in thus treating growths even when they are in close proximity to the eyes Involvement of the eyelid itself is not always a bar to successful treatment by diathermy. Reaction in the treated area and its surroundings is often alarming upon the day following the use of the diathermic cautery; but in this general disturbance lies much of the value of the procedure Nor is the invasion of superficial layers of bone a contra indication. Such layers may be devitalised, and are then either thrown off within a few months, or remain in statu quo for long periods. Some time ago Dr E P. Cumberbatch showed us at a meeting of the Electrotherapeutic Section, Royal Society of Medicine, a case of epithelioma of the scalp, which had been treated many years previously by diathermy An area of necrosed bone about the size of a shilling was visible at the vertex of the skull It gave the patient no trouble, and the disease had not recurred.

In the case of subjects in good general health, for a basal cell epithelioma to have reached the stage of bone invasion generally argues carelessness or fear on the part of the patient. We cannot prevent the recurrence of rodents, even when they are treated early and in the best manner possible. But the free interval should be one of years, and a return, if it does occur, ought to be dealt with immediately upon the lines above suggested This demands coöperation between patient and doctor When such coöperation is forthcoming, I am firmly convinced that the terrible ravages which are still sometimes seen as a result of this disease need never occur.

I should say, almost never. For to this optimism there is *one exception*. The control of any form of cancer depends ultimately upon the stimulation of natural powers of resistance, local and general. In a healthy man the defensive mechanisms, suitably evoked, are always capable of dealing with one small malignant focus. But when the victim is the subject of some intercurrent disease, it may be quite impossible to stop the spread even of a small rodent. A basal cell epithelioma which is healing well under suitable therapy may, in the presence of a severe attack of influenza, suddenly run amok. Such unfortunate cases call for the utmost skill and care in deciding what shall be done. When the illness is acute it is probably best to suspend local treatment until constitutional recovery has taken place, and then deal radically with the growth by diathermy. In the case of chronic debilitating complaints, it is only too probable that the rodent will continue to spread in spite of anything that we can do; but treatment of the whole body by various forms of light may help in some cases.

*Cosmetic Results*—The best results from the point of view of appearance are those where some form of radiation has alone been used to effect a cure This is, no doubt, due to the fact that radiation does not add anything to the destruction which has already occurred as a result of necrosis of tumour tissue. Repair commences at once, whereas all other methods in greater or less degree destroy some of the healthy tissues In any but very large growths the scarring which follows a properly carried out diathermic cauterisation is, however, remarkably small. A great deal depends on care in after-treatment. It is essential after diathermy to secure a healthy raw surface, just as is the case after curettage. After the first fortnight loose sloughs should be from time to time gently removed by forceps, and it is most important to treat the granulating surface by X rays. If there is any tendency to sluggishness an occasional erythema dose of ultra violet rays will expedite healing.

### *Summary.*

(1) Radiotherapy is the treatment of election for "virgin" rodents (2) In the case of a recurrence, rays of a different wave-length from those originally used should be employed. (3) If improvement is not manifest within a month some method of resensitising the tissues, as by curettage or ionisation, should be resorted to, after which radiation may again be given a trial (4) If the above methods are not producing definite and continuous improvement at the end of two months the diathermic cautery should be employed This method owes its success not merely to destruction of cancer cells, but to the sharp reaction produced in the surrounding tissues. (5) If all recurrences are dealt with promptly there should be no need for surgery in the ordinary sense of the term. When, however, the recurrence has already assumed large proportions, it may be necessary to invoke the aid of the plastic surgeon to make good what has been destroyed

A CASE OF

# ACUTE FATAL MEDINAL POISONING,

WITH NOTES ON THE ILL-EFFECTS OF THE MEDINAL HABIT

BY E. STOLKIND, M.D. (MOSCOW AND SIENA).

MANY cases of veronal poisoning have been recorded, but I have been unable to find a single record of fatal poisoning with medinal The following case is the more interesting in that the patient had taken medinal for insomnia three, four, and sometimes five times a week for more than eight years. He had become accustomed to the drug, and was thus obliged to take increasing doses Another remarkable feature of the case was the ill-effects of the medinal habit (medinalism) on the patient's physical and mental condition. Medinal is the sodium salt of veronal (diethyl barbituric acid). It is soluble in about six times its weight of water and has a bitter taste. It is eliminated very slowly, mainly by the urine.

I first saw the patient in the summer of 1916. He was a retired literary man of 61, who came of a healthy family and was a good swimmer. Once in 1916 I saw him in the morning when he did not wake up as early as usual. On being roused he resembled a drunken person; his speech was indistinct, thick, and slightly stammering. At the time this condition was due to the cumulative action of medinal, which he had often taken during the preceding weeks in the same doses. He refused to give up the drug and went on taking it for seven and a half years.

In spite of a good appetite he continued to waste and even his muscles became thinner and thinner. He was very anæmic. He passed water once or twice in 24 hours, and in small quantity—about 10 oz. He became weaker and weaker, and during the last year he was very exhausted, often being unable to perform a little physical exercise. He suffered frequently from palpitation. There was ataxy, resembling that of a drunken person, with tremor of the extremities and of the tongue.

Most remarkable, however, was the change noticed in his mental condition. His intellectual weakness gradually increased. He seemed continually depressed and was frequently very excited and worried over trifles. His thinking, speaking, and writing capacity, as well as his actions, grew slower and slower. To find a proper expression for his thoughts took him more and more time. The speech was often indistinct, not seldom stammering, whereas before he had been a good public speaker. During the last months his memory got worse; it became difficult for him to remember anything. At last he became slow in comprehending what was said to him, and often, after taking medinal, he was incoherent, and sometimes had delusions.

On Dec. 10th, 1924, he went to bed at about 11 P.M., but did not sleep till about 4 A.M., after taking medinal. In order to avoid constipation and prevent toxic symptoms he was in the habit of taking a teaspoonful of an alkaline salt immediately after the medinal. (He took part of a teaspoonful of the drug from the bottle.) On the morning of Dec. 11th I arrived, eight hours after the poison was taken. I found on the table two bottles of medinal, but none of the alkaline salt. Exhausted and drowsy, the patient had taken a large overdose of medinal instead of the salt.

I found him in a deeply comatose state. The pupils were small and later became smaller. They did not react to light and there was no corneal reflex. At first the conjunctival reflex was present, but later it disappeared and the sensory system was completely paralysed. The lips were cyanosed and there was a large amount of mucus in the mouth. The skin became moist and the extremities were not cold. Breathing grew more and more stertorous; at first there were 24 respirations per minute, on the next day they were 45. On the first day the pulse was weak, regular, 96 per minute, but on the next day the rate rose to 150. The temperature was normal; the urine had to be withdrawn. All my efforts to rouse the patient from stupor—by washing out the stomach, administering hot coffee, injecting various stimulants hypodermically, &c.—did not succeed, and he gradually became worse, showing signs of congestion and œdema of the lungs, and died 39 hours after taking the medinal.

A *post-mortem examination* was made by Dr. C. T. Parsons with the following findings: Body wasted; skull thin; pia-arachnoid thickened and congested. Calcified atheroma at the base of the aorta. Cerebral arteries macroscopically normal. Both lower lobes of the lungs deeply congested and œdematous. Some petechiæ in the mucous coat of the stomach. Spleen very soft. All other organs normal.

Examination of the urine with Millon's reagent, &c., showed the presence of medinal.

### *Conclusions.*

(1) Medinal can cause fatal poisoning in the same way as veronal. (2) The cumulative toxic effects of medinal are the same as those of veronal. (3) The medinal habit (chronic medinal poisoning or medinalism) has the same toxic action and produces the same after-effects on the physical health and mental condition of the patients as veronal poisoning. It produces almost the same ill-effects on the character of the patients as morphine.

Hampstead.

Clean Milk and Food Exhibition.—The Minister of Health will open a Clean Milk and Food Exhibition at Christ Church Hall, Edison-road, Crouch End, on Tuesday, March 2nd, at 2.30 P.M. The exhibition, which has been arranged by the medical department of the borough of Hornsey and will last four days, is to be purely educational and will include special morning sessions for school-children.

# UNEXPECTED MATERNAL DEATHS OCCURRING DURING PARTURITION AND EARLY IN THE PUERPERIUM.

By J. St. George Wilson, *M.C.*, Ch.M. Liverp., F.R.C.S. Eng.,
ASSISTANT SURGEON, LIVERPOOL MATERNITY HOSPITAL; HON. SURGEON, SAMARITAN HOSPITAL FOR WOMEN; HON. ASSISTANT GYNÆCOLOGICAL AND OBSTETRIC SURGEON, ROYAL INFIRMARY, LIVERPOOL;
AND
ERNEST GLYNN, F.R.C.P. Lond.,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF LIVERPOOL.

(*From the Thompson Yates Laboratory, University of Liverpool.*)

Three years ago one of us described six cases in which death not only occurred unexpectedly, but also the cause remained undiscovered post mortem until after a bacteriological or histological examination. Four were cases of acute pneumococcal septicæmia (two in children), the fifth in an infant was early tuberculosis with a terminal infection of *Streptococcus fæcalis*; the last was also in an infant who died after tenotomy, apparently from status lymphaticus, but really from acute encephalitis (Glynn and Dun). We now describe two cases of unexpected death associated with pregnancy in which the true cause was again only determined after investigations subsequent to the post-mortem.

### *Death during Parturition from Acute Streptococcal Septicæmia following the Induction of Premature Labour.*

Case 1.—E. J., aged 42, a 6-para, 37 5/7 weeks pregnant, was admitted on March 6th, 1924, for the induction of premature labour. At 4 P.M. two bougies were inserted into the uterus with the usual antiseptic precautions. On March 7th, at 6 A.M., the patient's temperature rose to 101·2° F., but during the next two days it was normal. On the 9th the membranes ruptured. At 6 A.M. on the 10th the patient's temperature was 99·4°. At noon she was given 0·5 c.cm. of pituitary extract intramuscularly as labour had not commenced and an examination revealed no dilatation of the cervix. At 12.15 P.M. she complained of severe abdominal pain, and a quarter of an hour later had a rigor lasting for 20 minutes followed by a rise of temperature to 102·6°. At 1.15 P.M., as she was restless and frightened, a hypodermic injection of omnopon, gr. 2/3, and scopolamine, gr. 1/150, was administered. At 2.15 P.M. her respirations were slow and shallow, and she rapidly became pulseless and died. Just before death the fœtal parts were plainly felt through the abdominal wall, and it was believed that the uterus had ruptured.

The autopsy and bacteriological investigation were made three hours after death by Dr. D. Riding. All the organs appeared normal except the spleen, which was slightly enlarged, pale, and soft; permission to examine the brain was refused. The uterus was removed intact with the fœtus and sent to Prof. Blair Bell's department.

*Bacteriological Investigation.*—The spleen-juice and heart-blood were examined immediately after the post-mortem. Both contained large numbers of streptococci in pure culture. This organism most resembled *Streptococcus mitis* (Hohlman). It was bile-insoluble, and killed in ten minutes at 60° C. It gave acid and clot in milk, acid in maltose, saccharose, glucose, and lactose broth, but no change in mannite broth or gelatin. Eighteen hours old broth cultures mixed with a 5 per cent. suspension of human red blood-corpuscles produced methæmoglobin. Two mice were inoculated intraperitoneally with 1 c.cm of an 18 hours broth culture; both died in 12 hours.

*Histological Investigation.*—Sections of liver, kidney, and spleen showed slight cloudy swelling, and some blood-pigment lying free in the blood-vessels or occasionally inside the leucocytes. The placenta was normal. A section of the decidual portion of the uterus showed acute inflammation—namely, vascular congestion and extensive leucocytic exudation; portions of the decidua and of the superficial layers of the subjacent uterine muscle contained much blood-pigment. No bacteria were seen except in the decidua and fragments of amnion; here diplococci occurred either singly or in clusters.

*Comments.*—The bacteriological examination, three hours after death, proves that the patient died with, and almost certainly from, streptococcal septicæmia.

The total duration of the septicæmia was between 4½ and 2 hours, for the temperature was normal at 10 A.M. and the rigor began at 12.15 P.M. This is very short. One of us, however, has described the case of a boy of 15 who died after 6½ hours illness from an infection with the pneumococcus (Glynn, 1913). Again, the infant referred to before, who died from a *Streptococcus fæcalis* infection, was acutely ill for only 7 hours. The short duration of septicæmia in a woman seems especially remarkable, as the *in vitro* test showed that the streptococcus was not really hæmolytic like *S. pyogenes*. The animal tests, however, proved that the streptococcus was very pathogenic for a non-hæmolytic one, as these organisms do not usually kill mice by the technique we employed (Glynn and Digby, p. 55). The presence of diplococci in the decidua indicates that the streptococcus entered the blood stream through the uterus. This may have occurred before midday, when the pituitary extract was given. The abdominal pain and rigor shortly after its administration suggest that the uterus contracted as a result of the drug and gave the patient a severe auto-inoculation.

### *Death Early in the Puerperium due to Delayed Chloroform Poisoning.*

CASE 2.—E. H. V., aged 29, a primigravida, commenced labour at full term on the afternoon of March 9th, 1924. She was still undelivered on the 12th. The os was three-quarters dilated, a hand presented with the head but the membranes were intact. The patient had chloroform "on and off" from 8 P.M. to midnight during an attempt at version, which failed. The chloroform was administered by a special mask, the total amount used being 12 drachms, no more than 3 drachms being given during any hour. The patient's reflexes were never abolished, and she quickly came to when the anæsthetic was stopped. At 11 P.M. her temperature was 103° F., and on the advice of Dr. Leith Murray she was removed to the Liverpool Maternity Hospital at 1.30 A.M. on the 13th. On arrival she was conscious, her temperature was 98°, and pulse 100. At 5.30 P.M. her pulse and temperature were rising and the fœtal heart was not heard; perforation was therefore performed by J. St. G. W. and the fœtus extracted. During this operation, which lasted half an hour, ether was given by the open method with the addition of a few drops of chloroform. On the 14th the patient's temperature was 97°, and the pulse-rate varied from 120–112. The pulse was weak and small. She vomited frequently during the day, most of the vomit being "coffee-ground." There was no jaundice. She was given rectal salines with glucose. On the 15th the previous 24 hours' urine was 2 oz. only, and she had passed none during the night. The patient was getting drowsy and was still vomiting "coffee grounds." The temperature was 97·4°, and the pulse was 100, weak and small. An intravenous injection of 15 oz. of 2 per cent. solution of sod. bicarbonate was given. The patient died at 1.35 P.M. on March 15th, 65½ hours after the first administration of chloroform.

The *post-mortem examination* was made by Dr. Riding. The uterus contained 1 oz. of sanious fluid, the endometrium was red and shiny, and hæmorrhagic areas were present in the uterine wall. The vagina was extensively lacerated and gangrenous in places. The right ovarian vein contained a thrombus, extending up to the vena cava. The liver was normal in size and firm, but rather pale; it showed a difference in colour between the centre and the periphery of the lobules. The spleen was enlarged and diffluent.

*Histological Examination.*—The pathological changes in the liver were very definite. There was extensive necrosis of the inner two-thirds of the hepatic lobule and extensive fatty "degeneration" of the outer third. The fat was most abundant at the margins of the necrotic areas; it was deposited in small droplets; the more or less degenerated cell nucleus was central, when present. The bile-ducts were normal. There was no round-celled infiltration and no fibrosis. A small amount of blood pigment was seen in the leucocytes lying in some of the blood-vessels, but there was no bile-pigment, leucin, nor tyrosin. Neither fibrin nor bacteria could be demonstrated by specific stains. The kidney showed a moderate amount of cloudy swelling and very extensive fatty "degeneration" of most of the secreting tubules.

*Comments.*—The clinical history and pathological changes prove that the patient died from delayed chloroform poisoning; though jaundice was absent, it does not always occur. The toxic effect of the chloroform may have been accentuated by the septic condition of the vagina. Death was not due to eclampsia because there were no convulsions. Besides, the changes in the liver were unlike those met with in this condition, for there was no *peripheral* necrosis, no hæmorrhage, and no fibrinous thrombi, while the fatty "degeneration" was too extensive.

We are indebted to Prof. Bell and to Dr. Murray for permission to report these two cases.

# Medical Societies.

## ROYAL SOCIETY OF MEDICINE.

### GENERAL MEETING OF FELLOWS.

AT a meeting of this Society held on Feb. 15th, Sir STCLAIR THOMSON, the President, occupying the chair, a discussion on

### FOCAL SEPSIS AS A FACTOR IN DISEASE

was opened by Prof. G. R. MURRAY (Manchester), who read the paper which appears in full in another column.

Mr. HERBERT TILLEY followed from the standpoint of the nose, throat, and ear. He said that sepsis in those regions had so many and far-reaching possibilities that it had been necessary for him to exclude its acute manifestations, as well as those resulting from direct spread of infection in the immediate neighbourhood of the primary focus. The path of organisms or their toxins to their destination might be either direct or indirect. Infective elements might be inhaled directly into the lower air passages and cause lesions in larynx, trachea, bronchi, lungs; or, when swallowed, might set up morbid conditions in the gastro intestinal tract. Indirectly, they might travel by the blood stream or lymphatics and produce disease in any distant organ. With regard to the faucial tonsils and the other constituents of Waldeyer's ring, he said he understood by a septic tonsil one which was subject to attacks of inflammation, associated with some enlargement of its corresponding cervical gland behind the angle of the jaw. The size of the tonsils was of little clinical significance unless, in children, there were symptoms of obstruction. Systemic symptoms were particularly liable to ensue from small, fibrous, septic, buried tonsils, which were frequently hidden behind purple-red faucial pillars. The mere presence of bacteria in crypts was no evidence of disease. Dr. G. B. Wood, of Philadelphia, pointed out the importance of realising the possibility of soluble toxins being absorbed from the tonsil directly into the blood stream. As an instance of mild toxæmia resulting from throat disease, he quoted the case of a lady who had occasional sore-throats and slight feverish attacks. She easily tired, and was not refreshed by extra sleep. She was anæmic, the tonsils were septic, and the jaw glands were enlarged and tender. The tonsils were enucleated, and she wrote later that she never knew what it was to feel really well until the tonsils had been removed. F. J. Poynton, studying rheumatic infection in childhood, analysed 1108 cases of primary attacks of acute rheumatism in children, and said that most of them developed along the lines of sore-throat, arthritis, and morbus cordis. Poynton considered the tonsils an important site of infection. Mr. Tilley recorded a case of chronic tachycardia in a boy from whom, after a week's rest in bed, the tonsils were removed; within ten days the pulse-rate became normal and had remained so three years. He knew many cases in which early types of arthritis, fibrositis, and myositis were cured by complete removal of septic tonsils. The influence of such infective foci in causing bronchial catarrh and bronchitis was most seen in children. In later years tonsillar disease seemed to cause anaphylaxis, as shown in vasomotor rhinitis, asthma, and urticaria. With regard to gastro-intestinal lesions, these, he thought, were more frequent following dental or nasal sinus sepsis than after tonsillar infection, owing to the larger quantities of pus swallowed from the former. The relatively smaller amount of material from the tonsil could possibly be dealt with by the gastric juice and healthy stomach. Subinfection of the kidney also occurred from nasal, faucial, and dental sepsis.

Mr. Tilley said his remarks applied equally to the accessory sinuses. The symptoms in young children were identical with those due to septic tonsils. When these sinuses were at fault the child had an obscure evening pyrexia, "growing pains," polyarthritis, bronchial and asthmatic symptoms; indeed, the clinical picture might mimic that of tuberculosis. S. T. Darling, of America, considered that lobar pneumonia was often a direct subinfection from accessory sinuses. And there was evidently a close association between bronchiectasis and brain abscess. Mr. Tilley had seen chronic myocardial lesions quickly relieved by treating the nasal sinuses. The nervous system was peculiarly liable to suffer from the effects of chronic toxæmia; especially were headache, migraine, and neuralgia likely to occur; also sciatica and peripheral neuritis; while retrobulbar neuritis in this connexion had already been discussed by the Society. In conclusion, he advocated the early removal of septic foci as the quickest means of cure, and asked that there should be a closer coöperation of all special workers in the domain of medicine. The aural aspect of the subject he dismissed by pointing out how frequently the general health was benefited by curing chronic suppurative otorrhœa.

Mr. F. W. **BRODERICK** (Bournemouth) dealt with the subject from the point of view of dental sepsis, pointing out the frequent association of arthritis, lessened sugar tolerance, and a depression of the autonomic nervous system. He said the presence of a granuloma at the root apex was a proof that Nature was setting up a good reaction in the body to the focal infection. A view now largely held was that dental conditions were an indication of a general systemic upset. The predisposing cause of caries was an alteration in the acid base equilibrium of the blood towards the acid side. Removal of septic teeth was often disappointing in results, and pyorrhœa seemed to be the result of an attempt to compensate alkalosis. He stressed the importance of the retention of some natural teeth by patients where this was possible, for adequate nourishment meant so much.

Dr. F. G. **THOMSON** (Bath) spoke of the influence of focal infection in the causation of arthritis. The term "rheumatoid arthritis" ought to be deleted from the nomenclature of the disease, "focal arthritis" being substituted. He insisted on the similarity of mechanism between ordinary arthritis and gonorrhœal arthritis. In 75 per cent. of the former gross infective conditions of teeth or tonsils could be demonstrated, and in many of the remainder there was an infection of the intestinal or the urinary tract. When one saw a case of multiple arthritis with a local infection, it was remarkable how the joint symptoms disappeared simply as a result of treating the focus. It was doubtful whether arthritis was due to the organisms themselves or even their toxins. As only a small proportion of cases having infection of teeth, tonsils, or urinary tract developed multiple arthritis, there must be some factor required for the latter to develop other than the sepsis, but whether this was associated with want of endocrine balance or other biochemical anomalies was matter for conjecture. But most cases of multiple arthritis showed an absence or great diminution of hydrochloric acid in the gastric juice, and this permitted secondary intestinal infection. With regard to the other group of chronic arthritis—namely, osteo-arthritis—here focal infection seemed to have no part; it was a degenerative condition associated with arterio-sclerosis and malnutrition of the joint, the determining factor being injury or strain.

Dr. F. C. **GRAVES** (Rubery Hill Asylum, Birmingham) dealt with the subject of sepsis as a factor in the causation of mental disorder. He had noted that in mental patients removal of purulent and septic foci was followed by greater stability in the circulatory and mental states. His contribution consisted of the exhibition of a series of lantern slides showing the actual dental and other foci, and the relation of the symptoms, with photographs of the patients before and after the treatment. Usually surgical removal of the focus was followed by an exacerbation reaction, this giving place later to definite improvement.

Mr. G. A. **PEAKE** also spoke from the dental standpoint, and referred to ocular complications of focal disease. He had seen especially good results from treatment of these foci in stomach disorders. He deprecated wholesale extraction of teeth on the slightest sign of dental trouble, especially as the patient was thereby deprived of a good means, by mastication, of keeping up the resistance of the body. At present, he considered the massacre of the teeth out-Heroded Herod.

Dr. E. **STOLKIND** agreed as to the close relation between dental defects and general disease, and said the too frequent advice of the doctor was to have all the teeth extracted. He quoted a number of his own cases to show that this advice was often founded on very slender causes. In a general way, he considered that the relationship between dental and general disease was much exaggerated, and that mere gingivitis, which would lend itself to special treatment, was made the excuse for rendering the patient edentulous. In cases in which the teeth were at fault and it was thought they should be removed, this should only be carried out after there had been a consultation between specialists.

Dr. P. **HAMILL** said there was a tendency, in all discussions of this nature, to concentrate too much on one particular region of the body. He thought cases could be divided into two main groups—those in which one was satisfied that focal infection was the cause of the patient's condition; and, secondly, those in which there was what might be regarded as a flank attack, which had the effect of diminishing the general health of the patient, and so allowing some unimportant condition of which he was the subject to become unduly prominent. In cardiovascular disorders he thought it would be agreed that infected tonsils were a very important factor; they at least were answerable for a continuance of the trouble. He instanced the delicate type of boy with a somewhat dilated heart, who showed a liability to faint, and had a raised pulse-rate and small rises of temperature. Yet his circulatory system was sound, as on most days he was able to join in school games. Frequently in such boys one could find a septic focus, removal of which mostly produced a dramatic effect. One case of grave myocardial disorder with auricular fibrillation which he quoted was proved later to have cholecystitis; after gall-stones had been removed his other symptoms became fewer and fewer, and he was being cured rapidly. A case of paroxysmal tachycardia he found to be associated with septic and defective crowns and bridges. He also spoke of the association of tonsillar disease with appendicitis, also of the latter with pus in the antra. He fully agreed with those who condemned the wholesale extraction of teeth; he regarded this measure as a mutilation; each separate tooth should be tried and weighed in the balance before being sacrificed. Many had seen infective processes exacerbating cases of exophthalmic goitre. And was it not possible that a long-continued sepsis exhausted the sympathetic thyroid side of one's economy? His own impression tended to that belief. In one of the cases of which a photograph was shown by Dr. Graves, the thyroid enlargement did diminish after the focal sepsis had been cleared away. It was common knowledge that an infective process embarrassed the carbohydrate metabolism and diminished the resistance of the patient.

The PRESIDENT said that as most medical men had now been coverted to a belief in the importance of focal sepsis, he would confine his brief reference to exhibiting four temperature charts of cases. The first was that of a case of pan-sinusitis. This gentleman was seized with an acute cold in the head and was in bed three weeks. There was suppuration in all his sinuses. The antrum was washed out, and a streptococcal infection was found there. The pain was so intense that his relatives thought he had meningitis. He got well of the sinusitis. Another was the chart of a hospital nurse who had an acute left-sided multisinusitis, and from her a pure culture of the influenza bacillus was obtained. She had only medicinal treatment, rest, and warmth, and made a complete recovery Another chart was that of another nurse, and her trouble also followed influenza, and the organism found in her sinus was the pneumococcus in pure culture. She also got well. The third was that of a girl of 17, who developed acute double sphenoidal sinusitis. She developed secondary abscesses in the neck. The sinuses were opened and drained and they each yielded streptococci. She had also thrombosis of the cavernous sinus, and death took place from meningitis. At the post-mortem examination, pus was found in the anterior fossa and in the orbit.

## SECTION OF NEUROLOGY

AT a *meeting of this Section, held on Feb. 11th,* the chair being occupied by Dr. H. CAMPBELL THOMSON, the President, a discussion on the

### *Sympathetic Innervation of Striated Muscle*

and its bearing on the treatment of spastic paralysis was opened by Dr. F. A. ADRIAN, who expressed the regret of neurologists that Dr. Hunter, of Sydney, was cut off in the midst of his valuable researches Though Hunter and Royle were not present to support their contentions, these latter must be subjected to the unsentimental scrutiny and criticism demanded by science. Hunter's theory seemed never to have crystallised completely, and the speaker felt that that worker *would himself have modified it if he had lived.* The main attention must be given not to theory but to matters of fact—i.e., the issues of experiments done Hunter and Royle put new life into the theory of the sympathetic *control of tonic contraction; they also* described an operation based on that theory for which they claimed benefit in spastic conditions and certain forms of paralysis The speaker said he did not think it could be held that the theory and the results of that operation necessarily stood or fell together.

Dr. Adrian proceeded to pass in review the physiological work which had been published on the sympathetic system and tonic contraction. Tone was a very difficult subject to investigate. It was now generally believed *that* accessory non medullated fibres existed in striped muscle, and that these supplied muscle fibres which were also innervated by medullated nerve fibres, and that they did not degenerate when the anterior roots were cut. These accessory fibres were innervated from the sympathetic ganglia. Several points were still doubtful; *for instance,* whether these fibres existed in every muscle or only in some; also whether they supplied a special part of the muscle-fibre which was not innervated by the medullated nerves. He entered into the pros and cons of these doubts Hunter and Royle believed that sympathetic fibres innervated separate muscle-fibres—namely, those of the red variety which contained sarcoplasm, and that those fibres were *not supplied* by the cerebro spinal system But all the evidence at present seemed to be against that view. Garvin had carefully investigated the *muscles* of the hedgehog—a peculiarly suitable animal—and had found no clear separation into two distinct kinds of fibre. What he found was a kind of infinite gradation from muscle-fibre rich in sarcoplasm to fibre which was poor in that substance. Still, it was possible that some fibre *might react* separately to two sets of nerves, one set might contract in one way, another set might contract in another.

*As soon as the existence of these accessory non-*medullated nerve-fibres had been demonstrated, attempts were made to discover their function. It seemed most likely that they were associated with the tonic form of contraction There were two distinct ways in which a muscle might behave; it might perform a series of rapid phasic movements, or it might hold a limb in a definite posture by maintaining a steady contraction. In the first of these forms a good deal of energy was used and the gaseous exchange was considerable, while fatigue occurred rapidly. There was also a fairly large electrical response. In the tonic contraction there seemed to be very little fatigue, there was a small energy exchange and a low *metabolism, and a small electrical* response. *In some* bivalves the distinction between these two kinds was very real and marked, and the two different kinds of contraction were carried out by separate muscle-fibres. In some animals destruction of the sympathetic on one side produced a decreased tone on that side, but in some cases it was impossible to know which side had been operated upon; tonic contraction seemed to go on in spite of the complete absence *of impulses coming down from* the sympathetic. Langeland considered that increase in spasticity did not mean the same thing as increase in tone as ordinarily understood. It did not mean that muscle developed a greater resistance to change in its length, but that it was pulled out more rapidly by a given weight. This was a very different conception from that afterwards introduced by Hunter and Royle. The classical experiment to demonstrate decerebrate rigidity had failed; it failed to *show a sympathetic* influence on tonic contraction. It seemed that the loss of the sympathetic did not produce that loss of nervous *impulse which was the immediate* cause of the change in length of the muscle, but it produced some trophic *factor without which* the muscle could not carry out tonic reactions so easily. It was not likely to be a direct effect on the muscle-fibre, comparable to the effect of the medullated nerves in causing *contraction.*

But it was chiefly the *facts* which were *in dispute;* there was considerable doubt even about the delayed sympathetic effect. Meek and Crawford, in America, carried out the operation of destruction of the sympathetic in dogs, and decerebrated them from 83 to 77 *days after the operation;* and they found no significant difference of any kind on the two sides, though they used very careful methods of investigation. Hunter's experiments on birds were more difficult to evaluate. The speaker said that on the experimental side *the balance* of evidence seemed to be against the view that the sympathetic sent out nervous impulses which had a direct controlling effect on the posture, length, or plastic tone of the limb muscles —i.e., an effect comparable to that *of the* cerebro-spinal impulses. But Hunter and *Royle* deserved the highest praise for having devised the operation of sympathetic ramisectomy for cases of spastic paralysis with excessive plastic tone. Some found this operation to be of great value, *others* failed with it. It was, however, only claimed to benefit those cases in which an increased plastic tone was the dominant feature. If the operation was successful it would not imply that the sympathetic exercised a direct control over the changes in the length of the muscle.

### *The Investigators' Work Reviewed.*

Dr. J. BEATTIE read the communication which was contributed for the meeting by Prof. G. ELLIOT SMITH. It consisted of a general review of the work of Hunter and Royle and other investigators on this subject, and was illustrated by a number of slides, some of them from the cinematograph film in the possession of Prof. Smith. *Hunter had found that* in goats there were two mechanisms in the hind brain controlling tone in the limbs, and that both these centres had to be cut off from their spinal cord connexions before complete relaxation of the limbs could be secured. Hunter also showed that the maintenance of tone in the limbs was not entirely dependent on Deiter's nucleus; that it resided in two centres, and only disappeared when both had been cut off from the spinal cord. He reminded the meeting of two important declarations of Sherrington—that the tone of skeletal muscle was a postural proprioceptive reflex, and secondly, that section of the sympathetic nerves did not render a group of muscles much more liable to fatigue than normal muscle. Muscle which was fatigued as a result of denervation became definitely toneless.

Prof. EDWIN BRAMWELL (Edinburgh) said the meeting had discussed the effect of division of nerves in animals on spastic conditions, but was it not possible to regard the matter from another standpoint? Were there any conditions affecting muscle in which phenomena were present which could not be accounted for by disease of the muscle itself? In this connexion he referred to the muscular dystrophies. It had been suggested that these probably had a neuropathic basis; but how were they to be explained? Was it possible they might be due to disease affecting the sympathetic? Histology only could supply the proof. Still, there were some facts of interest, notably the histological appearance of muscle in muscular dystrophies and the vasomotor changes met with in some of these cases, as evidenced by marbling of the skin, which could not be explained by a pure muscle condition. Could not the sympathetic be responsible?

Mr. A. S. BLUNDELL BANKART said his operative experiments in this relation had yielded chiefly negative results. He felt grateful to Hunter and Royle for having demonstrated the feasibility of cutting off the sympathetic supply to a limb by excising the sympathetic, and he had done that ten times in seven patients. The first case in which he attempted it—a very old-standing spastic paraplegia—was a technical failure, though the patient was eventually none the worse. The operations in the other cases were demonstration operations; he was sure the correct rami communicantes were destroyed. The only cervical operation he did was on a woman aged 34, who had, as a sequel of encephalitis lethargica, generalised rigidity, with great increase of muscular tone in all the limbs, though chiefly in the upper ones, and on the right side more than on the left. Following the operation there was a transient diminution of the spasm and some swelling of the limbs due to increased vascularity. But this passed off and a week or two after the operation the woman was no better. An illustrative example of the lumbar cases was that of a girl aged 13, a typical cerebral diplegia, with marked spasticity and contracture of all the limbs. He operated first on one side then on the other, and there was a dilatation of the whole limb after the operation. Also, it was agreed that there was a diminution of muscular tone, and the limbs were moved somewhat more freely. The speaker, however, could not persuade himself that the operation had been of any definite benefit to her. None of the results in the other cases could be regarded as hopeful, therefore he did not propose to do the operation any more until he saw some strong additional reason.

Dr. F. M. R. WALSHE made a few remarks in justification of the position he had taken up on this subject, and which had been commented on in one of the contributions. He said that in Hunter's experiments on sea-gulls, in which he produced an effect on the wing by cutting the posterior roots, he must have cut, in order to get that result, something else besides the posterior roots; the anterior roots must have been damaged too. He contended that there was no evidence that muscle tone could be divided into component parts, and if he was right in that contention, the theoretical aspect fell to the ground.

Mr. G. JEFFERSON (Manchester) said that his trial of the operation suggested by Hunter and Royle had been confined to the human subject. He observed the wave of ramisectomy spreading to this country when he was in the United States in 1924, and an Australian arrived at Cushing's clinic in the States when the speaker was there with much enthusiasm for the operation and statements of great benefit having accrued in the matter of loosening of limbs. He himself saw a surgeon operate on an arm, removing part of the cervical sympathetic, but with very slight immediate result, to everyone's disappointment. It had been said by some that technique or judgment had been at fault. Therefore the speaker, on reaching this country, sought opportunities of sympathectomising patients, and he had done it on six—five on the upper limb, one on the lumbar sympathetic. From the therapeutic standpoint of view his results coincided with Mr. Bankart's. All were hemiplegias, and all except one of the patients were under 20 years of age. Not one of those patients had received any benefit whatever from the operation. Some admitted that for a time the limb felt warmer, but one could not detect any difference in any respect. His conclusion was that the operation on the human being was not worth while.

Dr. ADRIAN and Dr. BEATTIE briefly replied.

## SECTION OF PSYCHIATRY.

### *Exhibition of Specimens and Laboratory Methods.*

A MEETING of this Section was held at the Maudsley Hospital, Denmark Hill, on Feb. 10th, Dr. R. H. COLE, the President, being in the chair, when various exhibits of pathological specimens were demonstrated and also laboratory methods used in the investigation of mental disease. Discussions took place upon the material shown.

Dr. C. LOVELL showed a series of brains from cases of anxiety psychosis and encephalitis, also slides and microphotographs of the brain and pancreas; in each of these cases the pancreas had been found to show inflammatory changes. His work on surface tension of the blood in such cases and the pathological findings had led him to think it probable that disordered pancreatic function was the underlying and predisposing cause rendering the organism susceptible to cerebral vascular disease or infection, just as diabetes mellitus predisposes the organism to staphylococcal infection. Treatment by a low carbohydrate diet and secretogen had proved of benefit in some cases, and had altered the abnormal surface tension.—In the course of the discussion, in which Colonel G. LORD, Dr. GRAHAM FORBES, Dr. A. PETRIE, and the PRESIDENT also took part, Dr. P. CLOAKE suggested that the pancreatic and other endocrine changes might be the result of disease of the sympathetic centres in the grey matter of the third ventricle.

Dr. F. GOLLA, with the collaboration of various workers, showed specimens of cerebral tumours in cases where there had been no signs of organic disease until shortly before death, and the PRESIDENT quoted a similar case recently seen at St. Mary's Hospital.—Colonel LORD and Dr. NICHOLLS showed a case of porencephaly which had apparently resulted from some disease at the age of 2 years, and Dr. CLOAKE commented on the cases as supporting the view that this condition is acquired and not a failure of development.—Slides from a case of the Lorain type of infantilism were shown by Dr. EFFIE BRANDER, in which the anterior lobe of the pituitary alone was affected, while other endocrine glands showed marked changes.

Captain MANN and Dr. ROBERTSON gave a demonstration of the use of various methods for determining basal metabolism, including those of Krogh and Haldane, and a modification of Benedict's apparatus giving graphic readings. The van Slyke microapparatus for estimating the basal alkalinity of the blood, and a new model for analysis of alveolar air were also shown. Colorimetric methods for the estimation of hydrogen-ion concentration of blood and urine were explained, and their use in demonstrating the normal alkaline tide after meals and its absence in certain psychotic patients.—Dr. SHEPHERD showed the Pachon recording apparatus designed for estimating the blood flow in the hand and its variations under emotion and the administration of drugs.—Dr. GOLLA showed an apparatus for accurate recording of the knee-jerk and the state of muscle tone.—Dr. LANDIS showed the electrocardiograph, and tracings taken from normal and psychotic patients before and after such stimuli as a sudden noise. He also demonstrated the use of an apparatus for the exact continuous recording of blood pressure and its variations under stimuli of different kinds.

---

## EDINBURGH OBSTETRICAL SOCIETY.

AT a meeting of this Society held on Jan. 13th Dr. R. W. JOHNSTONE, the President, took the chair, and Prof. J. A. KYNOCH (Dundee) read a paper on

### *Three Cases of Cæsarean Section,*

in which the operation had been required on account of some unusual occurrence.

The first was a 8-para, suffering from severe internal accidental hæmorrhage, who was in a collapsed condition before operation was performed. Cæsarean section was done as quickly as possible, and on opening the abdomen the uterus was found to be congested and hæmorrhagic, with here and there purple mottled patches. There was concealed hæmorrhage in the left broad ligament, and the left Fallopian tube presented the same hæmorrhagic appearance. The child was delivered and the uterus was stimulated to contract by means of pituitrin and by hot towels. This was carried out for at least 10 minutes before the contractions became satisfactory, after which the uterus and abdomen were closed. Although in a very weak state after the operation the patient made an uninterrupted recovery and left the hospital in three weeks.

The second case was one of prolapse of the cord in a 2-para whose first confinement had been difficult on account of a slightly contracted pelvis and had resulted in the birth of a child which did not survive. On her admission for the second confinement the cervix was slightly dilated and the cord was found to be prolapsed, but there was still pulsation and the fœtal heart sounds were satisfactory. On account of the contraction of the pelvis Cæsarean section was decided upon and a living child was delivered.

The third case was one of funnel-shaped pelvis, which Prof. Kynoch deemed to be more common even in this country than was generally supposed. The head had remained on the pelvic floor and had been making no progress for four hours; on examination the subpubic angle was found to be so acute that barely two fingers could be admitted. The diameters of the outlet were: inter-tuber-ischial, 3¾ in., posterior sagittal, 3 in. On account of these measurements and the acuteness of the subpubic angle, spontaneous or instrumental delivery was impossible, and it was therefore a question whether pubiotomy or Cæsarean section should be the treatment. As the patient was a primipara, Cæsarean section was decided upon, and a 7 lb. child was delivered. Both mother and child made a satisfactory recovery

Prof. Kynoch pointed out that the first of the three cases made it clear that, sometimes at any rate, a uterus with severe internal accidental hæmorrhage could be stimulated to contraction by the use of hot towels and pituitrin, and hysterectomy could be avoided.

### *Operation for Rectocele.*

Prof. B P. WATSON read a preliminary communication on his technique for the cure of rectocele. The essential feature in his operation, he said, was the isolation of the special fascio muscular sheet which supports the rectum and which is deficient in all cases of rectocele. The condition does not occur, even when the levatores ani muscles and their fascia are badly damaged, as long as this rectal fascia remains intact. The fascia lies deep to the levator ani muscle in close relation to, and supporting, the anterior rectal wall. It is in intimate relation with the posterior vaginal wall in its middle third, and becomes continuous at the sides of the cervix with the pubo-cervical layer of fascia—the essential support of the bladder. The operative treatment recommended for rectocele consists in defining and freeing this fascia and then repairing it after replacing the herniated rectum. Prof. Watson described the operation in detail. The essential points were as follows. A flap of the posterior vaginal wall is raised by inserting closed scissors midway between the middle line and the limit of the muco-cutaneous perineal incision on either side. The scissors are passed beneath the postero-lateral vaginal wall, well to the side of the rectum, and are opened out. In this way the natural line of cleavage is easily found. Dissection is then carried out towards the middle line where scar tissue obliterates any definite layers. This scar tissue is easily dissected off the rectum from the sides and the dissection is carried to the upper limit of the rectocele. As this is done two bands of tissue appear, which are firmly attached to the under surface of the vaginal flap. Between them, in the middle line, there bulges the rectal wall. These bands are the edges of the torn rectal fascia and when the dissection is carried out to the upper limit of the rectocele they are found to unite in the middle line. This fascia is freed and then united over the rectum by continuous suture. By this means the rectocele is cured. The perineum is built up in the usual way. The chief point in the operation, said Prof. Watson, was the separation of this rectal fascia from the under surface of the levatores ani. This was done by blunt scissor dissection, and thus the fascia could be sutured separately and not along with the muscle as was usually done. By this means there was no tension and better healing and more accurate apposition was ensured. The operation was more correct anatomically than the usual procedures in cases of rectocele and had given excellent results, no recurrences of a rectocele having ever been reported after its performance.

### *Post-partum Convulsions.*

Dr. E CHALMERS FAHMY described a case of post-partum convulsions which had presented difficulty in diagnosis.

The case was one of a 1-para, who was admitted in labour to the Royal Maternity Hospital, Edinburgh. The first labour had been uneventful, and throughout the second pregnancy she had been well except for slight œdema of the feet and legs. On admission the blood pressure was normal and there was only a slight trace of albumin in the urine. She was delivered spontaneously, and the placenta and membranes came away complete. Twelve hours after delivery she complained of headache and difficulty of vision. Morphia was given at once, but a fit developed. The usual treatment for eclampsia was then administered, but a second fit occurred one and a half hours later There was albumin (1·4 per cent.) in the urine, but the blood pressure was only 140/98 mm. Hg. The patient became drowsy on recovering from the fits, and this drowsy condition lasted for seven days. The blood pressure for these days was never above 130 mm., and the albumin decreased by degrees. On the seventh day after delivery fits recurred, and within 12 hours she had 11 fits. Lumbar puncture was done, and some clear fluid under increased tension was withdrawn. No micro-organisms were found in the fluid There was now only a slight trace of albumin in the urine. The patient again became drowsy, but consciousness returned in a few days and she became perfectly well, being discharged from hospital after a further three weeks. At a subsequent pregnancy a healthy child was delivered without any signs or symptoms of toxæmia, and during this pregnancy there was no albumin in the urine.

Diagnosis, said Dr. Fahmy, was very difficult. In his opinion the fits were due in the first place to eclampsia; this was followed by drowsiness, culminating in fresh convulsions due probably to the brain being affected by the toxæmia. Possible diagnoses of hysteria, epilepsy, and a lesion of the brain were ruled out, but it was difficult to exclude nephritic toxæmia definitely. The patient's subsequent pregnancy, in which there was no albuminuria, made the diagnosis of nephritis unlikely.

---

*Corrigendum.*—Mr E. B. Fuller, who took part in the discussion on pyelography at the Section of Urology of the Royal Society of Medicine on Jan. 28th (THE LANCET, Feb. 6th, p 289), is lecturer in clinical surgery at the University of Cape Town.

## NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Jan. 21st, when Mr. H. BELL TAWSE, the President, took the chair, and Sir WILLIAM MILLIGAN (Manchester) delivered an address on

### *Radiodiathermy for Inoperable Malignant Disease of the Upper Air and Food Passages.*

After demonstrating the action of diathermy by lantern slides showing the effect on a piece of pork of the various discs and buttons used in practice, he enunciated the following principles of treatment: (1) The indifferent electrode must be wrapped in numerous folds of lint soaked in salt solution. (2) The diathermy point—the active electrode—must be in contact with the tissues before the current is turned on. (3) The current must be very slowly increased. (4) When "sparking" occurs, the current must be switched off. (5) The button should not be removed till the current ceases. (6) No single sitting should exceed 20 minutes, as up to this limit there is practically no shock.

The most favourable cases for diathermy, he said, were those in which malignant disease affected the nasopharynx, palate, tonsil, and oropharynx. Where there was secondary involvement of glands block dissection should precede diathermy and the lymphatic area should be irradiated with radon needles or applicators, or both. There were cases in which the growth disappeared and the patient remained free from recurrence for periods varying from one to seven years. When it was found that glands were inoperable, the destruction of foul, painful ulcers gave immense relief to the patient. In all cases preliminary ligature of the main blood-vessel to the area was desirable so as to lessen the risk of secondary hæmorrhage, which was liable to occur about ten days after operation, when sloughs were separating. For removal of the tongue the diathermy knife was superior to the scalpel. The results of treating inoperable growths in the hypopharynx and larynx had proved rather disappointing, whether diathermy was preceded by or followed by radium, and amongst possible complications were œdema of the glottis, inability to swallow, necrosis of cartilage, and stricture. Preliminary tracheotomy became essential and preliminary gastrostomy might become so. The Brussels school employed diathermy in operable intrinsic cancer of the larynx through a window in the thyroid cartilage. In closing his address Sir William Milligan expressed the hope that general surgeons would more often prefer the diathermy knife to the scalpel in both operable and inoperable malignant disease.

The PRESIDENT said that operation frequently revealed extensions which placed the cases in the inoperable category. Although both radium and diathermy seemed in rare cases to stimulate the growth of malignant disease, the excellent results were sufficiently numerous to overshadow them.

A number of members took part in the discussion.

---

A CONFERENCE ON MILK.—The "Grade A (Tuberculin Tested)" Milk Producers' Association is arranging a conference at University College, Reading, on March 23rd and 24th. A similar conference was successfully held by the Association in 1924. Subjects to be discussed will be the present position of Certified and Grade A (Tuberculin Tested) Milk in Scotland; the steps taken by the Ministry of Agriculture to promote the production of graded milks; the cost of producing Grade A (Tuberculin Tested) Milk; the value of the tuberculin test to the dairy farmer; the growth of grade milk production; and the control of tuberculin tested milk from its source to the consumer. Visits will be paid to graded milk producers' farms, to distributors in the district, to the College Farm and the National Institute for Research in Dairying. Hostel accommodation at moderate rates will be provided at St. Patrick's Hall, University College. Information may be had from Lieut.-Colonel C. Maddock, C.I.E., M.D., Foxglade House, Shinfield, Reading.

# Reviews and Notices of Books.

### EDUCATIONAL PSYCHOLOGY: ITS PROBLEMS AND METHODS.

By CHARLES FOX, M.A., Christ's College, Cambridge, Director of the Training of Teachers and Lecturer in Educational Psychology in the University of Cambridge. London: Kegan Paul, Trench, Trübner and Co., Ltd. International Library of Psychology. 1925. Pp. 380. 10*s.* 6*d.*

THIS book is a worthy addition to a series of outstanding merit. Ostensibly it deals with the contributions made by experimental psychology during the last quarter century to educational problems, but the volume surveys a wider field and embodies a definite point of view. The author's attitude to one school of psychologists is epigrammatically summarised in his description of a well-known psychological text-book by a Behaviourist as an "excellent book on physiology." And he is a vigorous opponent of the idea that by analysing mental life into its elements we shall have explained it, being an adherent of the "Gestalt" school of psychology, which holds that "there is no such thing as a mental factor isolated from others, but all mental life has a structure, a pattern *ab initio.*" Mental phenomena do not explain mental life any more than the notes explain a melody. Association will not account for the reduction to order of the chaos of disconnected movements, sensations, and ideas usually supposed to be the units of mental life.

With regard to mental images, he contests the widely held view that they only differ from sensations in respect of quantity and contends that there is a real difference in quality. He finds confirmation of this in Galton's account of the responses to his questionnaire on mental imagery; Galton was surprised that scientific and other thinkers had so feeble powers of visual representation, but the author interprets this as meaning that their introspections were more accurate than those of the less trained observers. Imagery plays but a small part in thinking; there is only a low correlation between vivid imagery and intelligence. Educationists will be interested in the author's conclusion that the particular type of imagery used in presenting a subject to the pupils makes little difference to the result, the learning process being much more dependent upon the mental make-up of the learner. Throughout the book he insists upon this personal element. Habit, for example, never results from mechanical repetition; there must be consciously directed effort on the part of the individual. With regard to memory, too, he insists that experimental evidence which fails to allow for the personal factor—the desire or will to remember—is valueless, and he produces strong evidence for his view. Similar fallacies attach to investigations on fatigue when psychological factors—the desire to do well or secure a reward, interest in the work, suggestion—are neglected. It is not so easy to accept his contention that a formed habit constitutes an impulse to action, an acquired impulse in contrast to the innate impulses which McDougall regards as the sole motives of action. His examples are not particularly happy. The effect of religion in moulding human nature is an instance of the action of a "sentiment" (in McDougall's sense) regulating inborn instincts rather than that of a habit. Religion can scarcely be called a habit, though it may produce habits.

There are interesting sections on heredity, showing a strong leaning towards the acceptance of the inheritance of acquired characters, and on mental tests. The chapter on fatigue is excellent; the essential point in the author's opinion is the diminution in the power of steady attention, the variability both in quantity and quality of the work done. The bibliography of literature on the subject is made more valuable by the author's notes, brief but pointed.

### EARLY TUBERCULOSIS IN THE ADULT.

*Die Klinik der beginnenden Tuberkulose Erwachsener.* Vol. III. By Dr. WILHELM NEUMANN, Professor in the University of Vienna. Vienna: Julius Springer. 1925. With 72 illustrations. Pp. 176. 14*s.* 3*d.*

THIS volume is divided into two parts. The first deals with changes in the lungs of non-tuberculous origin, the symptoms of which may simulate early tuberculosis. A careful description of changes caused by tumours, primary and secondary, of the bronchi, lungs, pleura and mediastinum, and by syphilis is given from the clinical and radiographic points of view, fortified, in some cases, by post-mortem records. It may be questioned if much advantage is to be gained from the clinical charts, which are freely reproduced, since the signs employed are not always easy to understand when no key to their significance is provided. Dr. Neumann emphasises the importance of careful search for the tubercle bacillus, and adopts Lawrason Brown's dictum that if bacilli are not found after repeated examination, bronchiectasis, syphilis, influenza, tumour, and Hodgkin's disease should all be considered and excluded. The second part of the volume deals with certain symptoms similar to those caused by tuberculosis, but due to other diseases. The most valuable section is that dealing with hæmoptysis and its association with tumours, cardiac and hæmophilic conditions, and hæmosialemesis, the expectoration of blood-stained morning fluid. Admirable, too, are the sections devoted to febrile and subfebrile conditions, to the influence of scoliosis in the production of atelectasis and deformities which give rise to changes in the percussion note, persistent crepitations and apparent wasting, and thus lead to wrong diagnoses. Although the lateral extension of Krönig's percussion area on the side of the scoliotic convexity is touched upon, nothing is said of the "compensatory" effect of greater fullness on the side of the convexity behind, flattening of the corresponding apex in front, and the reverse changes on the side of the concavity. Clinical records from the author's own experience are freely supplemented by the records of others. The care taken to enumerate and illustrate so many different conditions makes the book rather difficult to read, but it is likely to be valued by those whose daily work brings them into close association with the difficulties described. At the end of the book is given a subject and reference index to the three volumes of the series which have appeared.

If subsequent volumes reach the same standard this work should be a valuable addition to the literature of tuberculosis.

### REMEDIES AGAINST THE PLAGUE.

The Earliest French Tracts Printed in the Fifteenth Century, Facsimiles, Notes, and List of all the Incunabula on Plague. Paris: A. C. Klebs and E. Droz. 1925. French edition, Fr.80; English edition, Fr.100.

THE literature of plague is enormous. The very titles of the works written about it fill more than 50 pages in the Index Catalogue. For hundreds of years the dread of it brooded over Europe, and the petition "from plague, pestilence, and famine, Good Lord deliver us" was put up daily in England as no empty form of words. This volume, the first of a series of scientific documents of the fifteenth century, is a dainty portfolio of pott quarto size, and contains in facsimile a Régime in French verse and two prose pamphlets on Remedies against the Plague. Mademoiselle E. Droz has herself edited the volume and acknowledges the help given by Dr. A. C. Klebs. She has performed the task with great judgment; she has not allowed herself to be beguiled into side issues, but has followed the straight path dealing solely with the tracts under her consideration. By this means she has recalled to memory Johannes Jacobi, of whom very little is known except that he was a physician at Montpellier, was appointed Chancellor of the University in 1364, treated the popes, and was left legacies by the Duke of Anjou and King Charles the Fifth. At the end of the facsimiles is a useful and seemingly complete bibliography of plague incunabula, the appearance of which would have rejoiced the heart of Sir William Osler. This work and that of Mrs. D. W. Singer on Plague Tractates, to which attention is drawn, are creditable attempts to introduce some kind of order into what has hitherto been chaos.

### GYNECOLOGIC UROLOGY.

By LYNN LYLE FULKERSON, A.B., M.D., F.A.C.S., Assistant Professor of Gynecology, New York Post-Graduate Medical School; Surgeon, Cornell University Medical School Clinic. London: William Heinemann, 1925. Pp. 247. 27*s.* 6*d.*

IN this book, which is devoted to the diagnosis and treatment of urological diseases in women, the first chapter gives a useful little chart for the taking of histories, and the two succeeding ones deal with abnormalities of the urine and the anatomy of the female urinary tract. A section on instruments is full and well illustrated. In the series of chapters on diseases, while the usual scheme of classification is adhered to, the author emphasises throughout the clinical standpoint, giving very little pathology. This part of the book is uneven; there is a good account of ureteral stricture with references to Hunner's work, but the treatment of incontinence and enuresis is passed over too lightly, and the description of the technique of diathermy is too brief. For the chapter on pyelography a most excellent series of radiograms has been collected, some showing distortion of the renal pelvis due to malignant growths. The writer expresses his preference for 12 per cent. sodium iodide as a medium. The book concludes with a section on operative surgery, of which, perhaps, the most interesting part is the treatment of various forms of fistulæ and of relaxed vesical sphincter. The omission of any description of litholapaxy is curious. It is apparent that Kelly's endoscopes are more used in America than in this country, and a modification of this instrument, which can be used with either air or water distension, has been invented by the author.

On the whole this little volume will prove useful to those who have felt the want of a work devoted entirely to female urology. The diagrams, both plain and coloured, are excellent throughout, and a full bibliography is included.

### MANUAL OF EMERGENCIES.

Medical, Surgical, and Obstetrical. Second edition. By J. SNOWMAN, M.D., M.R.C.P. London: John Bale, Sons and Danielsson, Ltd. 1926. Pp. 301. 10*s.*

THERE are not many good English text-books which deal solely with the common emergencies which threaten life, and Dr. Snowman's manual in its second edition is therefore welcome. First published in 1919, it was based largely upon the English edition of Lenxmann's "Emergencies in Medical Practice," and it has now been effectively revised. The additions include descriptions of the surgical treatment of angina pectoris, the insulin treatment of diabetes, botulism and its treatment by serum, and the treatment of auricular fibrillation by quinidine sulphate. The last-named section is, perhaps, too simplified; the dosage of quinidine is rather a complicated subject and cannot be safely dismissed with advice to give 3 gr. doses. Prof. Stroganoff's treatment for eclampsia is also included. With regard to one important subject—viz., that of cerebral hæmorrhage and thrombosis—the treatment described is not that of the most modern teaching. Purging and venesection for cases of cerebral hæmorrhage are now considered incorrect by some authorities on the grounds that cerebral hæmorrhage nearly always causes a fatal termination and such treatment is the worst possible for cerebral thrombosis which may be present despite high blood pressure and in which the prognosis is much better if correctly treated. In describing the treatment of infantile diarrhœa no mention is made of the very valuable method of giving saline by the intra-peritoneal route. Apart from these points this new edition seems to be quite sound. The publishers announce that the size and bulk of the book have been reduced so as to enable it to be carried in the pocket. This seems a doubtful policy. It is unlikely that anyone will want to carry the book about always, and if it has to be looked for hurriedly on a bookshelf a larger size is at least no disadvantage.

## The Birmingham School of Medicine.

*William Sands Cox and the Birmingham Medical School.* By J. T. J. Morrison. 1926. Pp. 240. 5*s.* *History of the Birmingham School of Medicine, 1825–1925.* Being a special number of the *Birmingham Medical Review*, December, 1925. Edited by K. D. Wilkinson, M.D. Birmingham: Cornish Brothers, Ltd. Pp. 96. 2*s.* 6*d.*

These two volumes are complementary. That for which Dr. Wilkinson is responsible is a general history of the Birmingham School, of its birth and begetting, its somewhat stormy infancy and adolescence, and finally of its growth to a vigorous manhood. Prof. Morrison's book deals with the life and work of the man, if any one man can be said to be the founder of the school, by whose energy and foresight the Birmingham Medical School came into existence. He deserves praise for having produced so full and readable an account in the short space of some five months, for it was only at the end of June, 1925, that he was commissioned by the Medical Committee of Queen's Hospital to undertake the task, and the book appeared in print by Dec. 1st.

The beginning of medical teaching in Birmingham was due to one Mr. John Tomlinson, surgeon to the town infirmary, who in the winter of 1767–1768 began a course of lectures in anatomy for the benefit of "the young gentlemen of the Faculty"—i.e., the apprentices of the medical men in the town. A few years previously the foundation of a General Hospital had been suggested and a committee of medical men and others was appointed to further the scheme. One of the rules proposed that each surgeon be allowed three pupils to attend the hospital for instruction. The hospital was intended to cost £3000 and to have something over 100 beds. Many difficulties were encountered; not until 14 years after the opening meeting of the committee was the hospital formally opened, and then only with 40 beds. The number of pupils admitted had been increased, for each physician and surgeon was allowed to have twelve pupils for instruction. For many years nothing further was done, until a young medical man, by name William Sands Cox, in partnership with his father, Edward Townsend Cox, conceived the idea of having a regular medical school in Birmingham, and commenced a course of "Anatomical Lectures with Physiological and Surgical Observations" at his house in Temple-row on Dec. 1st, 1825. The plan had the approbation of the leading medical men of the town, but still difficulties arose, and Cox was not a man who possessed the saving grace of suffering fools gladly. However, eventually he triumphed, and by 1843 the school received a charter from Queen Victoria, being named the Queen's College. Three years previously the foundation-stone of Queen's Hospital had been laid, this building being intended to serve as a clinical hospital for the school. Cox's chief ally, without whose generous cooperation the scheme might never have matured, was the Rev. Dr. Warneford, Rector of Bourton-on-the-Water, a man of great wealth, which he employed in many philanthropic works. His name is kept green by the Warneford Asylum near Oxford, though his benefactions to Birmingham are nowadays less well known. In 14 years he contributed no less than £27,000 to Cox's various schemes, though his strict theological views were the source of some inconvenience. He was anxious that the college should be conducted upon Church of England principles, and although he had confidence in the original staff, yet he feared that after their death "future Satanic subtlety" might have to be met, and that "to guard against the subtle designs of the Jesuits and the insidious intrusion of malignant dissenters, imperatively requires much deliberation." The further progress of the school until the blossoming into being of the University of Birmingham, and the details of the generosity of Sir Josiah Mason, must be sought for in the volumes before us.

There is one statement in both books which requires modification in our opinion. Dr. Wilkinson (p. 34) and Prof. Morrison (p. 71), in speaking of the perfectly just claim of Queen's Hospital to be the first provincial hospital established for the provision of clinical instruction, go on to point out that even in London the only two hospitals which had this "educational character impressed as the prime reason for their existence" (Morrison) were University College and King's College. This statement is historically incorrect. University College was founded in 1834, King's College in 1839, and Queen's Hospital, Birmingham, in 1840. But the right to be called the premier hospital in London definitely founded for educational purposes belongs to Charing Cross. In 1818–1820 provision was made by its founder, Dr. Benjamin Golding, for the education of a certain number of free pupils belonging to "respectable but unfortunate families," and in Dr. Golding's own words, "the want of a university as far as medical education is concerned will be fully supplied." Birmingham may well be proud of her University and of the small beginnings from which it grew.

## Middlesex Hospital Papers.

*Published Papers by Members of the Staff of the Middlesex Hospital Medical School, 1924–25.*

This collection of 21 reprints represents various aspects of the work carried out at the Middlesex Hospital during the year 1924–25. Sir John Bland-Sutton's Lloyd Roberts lecture on Attic Salt for Gall-stones is a fine example of the mature observations of a well-stored mind. Important papers on Splanchnic Analgesia, by Mr. O. S. Hillman and Dr. R. Apperly; on Radiation Therapy, by Dr. J. H. D. Webster; and on Lupus in its Surgical Aspects, by Mr. W. Sampson Handley, are examples of the year's research work on the clinical side. Much work has been published from the various laboratories attached to the hospital. Prof. E. C. Dodds and Dr. F. Dickens contribute a paper on their simple method for the preparation of insulin by aqueous extraction. Dr. P. R. Peacock and Mr. B. D. Watters discuss certain aspects of ultra-violet rays, while Prof. S. Russ deals with the pathological basis of radiation. Reports on cases of interest, pathological observations, and certain physiological research work complete the volume.

## Calorimetry in Medicine.

Medicine Monographs. Vol. IV. By William S. McCann, Associate Professor of Medicine; Associate Physician, Johns Hopkins Hospital. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. Pp. 98. 11*s.* 6*d.*

This book gives an excellent short account of calorimetry in medicine, dealing for the most part with the extensive work that has recently been carried out on basal metabolism in disease. The author is wise enough not to give space to the description of various kinds of apparatus, though he does discuss at some length, and with clear precision, the different normal standards of basal metabolism that have been adopted, and adds useful tables. He is thus able to devote the greater part of the book to an account of the effect of disease and drugs on basal metabolism. The effect of the ingestion of food on metabolism is also dealt with and the specific dynamic action of foodstuffs. Short sections on the mechanical efficiency of the body and of the total energy requirement in disease are included, while a good bibliography concludes the volume.

# When in doubt—?

SINCE the introduction of Dimol the successful treatment of putrefactive and other bacterial invasions of the intestinal tract, and conditions arising therefrom, has been established beyond question.

Medical men are constantly reporting cases where Dimol has been especially effective, and describing conditions—until recently not associated with intestinal infection—which have been distinctly benefited by its use. This would seem to bear out the contentions of Charcot and Metchnikoff that 90% of all human ailments have their origin in intestinal toxæmia.

The careful practitioner, when in doubt, will bear this in mind now that we have a really efficient and non-toxic intestinal bactericide—*not a mere antiseptic.*

It must be remembered, however, that Dimol is not indicated in cases where the disturbance is of a purely chemical origin—i.e., where the causal agent is not a micro-organism ; Dimol acts solely as a bactericide.

The efficiency of Dimol in the treatment of putrefactive and other bacterial invasions of the intestinal tract is conclusively told in the interesting clinical reports which, together with the brochure describing the chemistry and pharmacology of Dimol, will be sent to any physician on application to the

# MEDINAL

TRADE MARK

**Mono-sodium salt of diethylmalonylurea.**

A readily soluble, safe and non-habit-forming hypnotic for internal, rectal and subcutaneous injection.

Medinal rapidly induces sleep of a refreshing and peaceful character, and as its action is confined to the central nervous system there are no secondary symptoms.

Being extremely soluble, it is rapidly absorbed and completely eliminated in a short time without the production of cumulative toxic effects.

**Medinal probably more nearly approaches the ideal than any other available hypnotic.**

(Vide reports of B.M.A. Annual Conference, 1926, at which several speakers of eminence recommended Medinal for Insomnia.)

*Samples and Literature on request from*

**SCHERING, LTD.,**

3, Lloyd's Avenue, LONDON, E.C.3.

## *Other Schering Specialities.*

**EUPHTHALMIN.**—A powerful and reliable mydriatic, presenting advantages over other agents. Mydriasis begins in 15 20 seconds and ends in 4-6 hours.

The very slight disturbance of accommodation lasts only 2 hours, and even during this period occupation can usually be continued.

Intraocular pressure is not influenced, so that Euphthalmin may be instilled even where glaucoma is suspected.

It is used in a 5 % solution, which may be sterilised by boiling.

**Original Packing : Bottles of 1 gramme.**

**ATOPHAN.**—Well known by reason of its property of eliminating uric acid to a degree unattainable by any other drug.

In addition it has powerful analgesic, antiphlogistic, antipyretic and cholagogue properties.

Indicated in gout, rheumatism, and all diseases associated with uric acid diathesis.

**VERAMON.**—A safe and potent analgesic which is "second only to morphia" in pain-relieving properties with none of the secondary symptoms of that drug.

Veramon will relieve "all possible forms of painful conditions" ranging from headache and toothache to tabetic crises usually without inducing sleep.

## IRREGULAR MEDICAL PRACTICE.

An American medical society, as may be seen from the letter of a correspondent last week (p. 363), has decided to admit laymen to its counsels as associated members. This is a most interesting decision. Where the educated public can join in the discussions of medical men and can recognise the reasons for the medical views, formulations of the public needs with practical suggestions for meeting them will be most welcome, and any such symposium should work well. It should lead to the support by a thinking section of the public of the cause of scientific medicine by demonstrating how far the educated physician and surgeon are usually aware of what the unqualified have to teach. Medical societies founded as such are not thrown open to the public frequently in this country because the discussions are generally too technical to afford an opening for those without professional training, but there is no reason why the principle of joint debating, so happily illustrated in the success of the Medico-Legal Society, should not be carried much farther. Joint debates would certainly attract curiosity seekers, but gratification of public curiosity need not always signify a concession to pruriency, and if the contributions of uninformed sensationalism to scientific debate would imply mere waste of time the way in which medical opinions are evaluated by laymen can never be too clearly known. The debate last week in the House of Commons on irregular practice calls pointed attention to the fact that the medical profession should consider whether its relations with the lay public would not be strengthened if more occasions were taken for open comparisons of views. The voice of authority in medicine has never gone unquestioned, and enlightened medicine has never wished that it should so go, but there has been an alteration in public attitude lately, the reasons for which it is desirable to understand. Medical authority is to-day not so much questioned as denied or ridiculed. Persons who know nothing of the groundwork or the outlook of medicine communicate to the daily press dogmatic opinions upon the real causes of cancer and the true remedies for tuberculosis; persons who have never heard of the Medical Acts from which the Medical Council derives its powers vilipend that body; persons who misconstrue the whole meaning of evidence attribute to hysterical impressions the value of scientific tests; and all this, when we have made deductions for commercialism and self réclame, is published, and we may credit it as being published, with the hope of introducing methods of healing along lines that shall be quicker or surer—anyhow better—than anything which progressive science can supply through the medium of trained and tried workers.

Much of this kind of misrepresentation the medical profession realises must always go on, and the real leaders of medical thought, having the mental habits and necessary acquaintance with the difficulties of reasoning, sympathise with the plight of intellectual people in trying to come to grips with medical positions. It seems such cold good sense to adopt the form of reasoning that where orthodox medicine cannot supply a remedy, members of the public ought to be given equal status with doctors in their efforts to cure disease. But there are gaps in the logic, the fatal ones being that disease has to be diagnosed before treatment can be administered, and that symptoms do not point conveniently to specific complaints for which definite treatment has been ascertained, but supply clues to conditions which can only be followed up by those with general scientific equipment. The motion brought forward by Dr. Graham Little, Member for the University of London, in the House of Commons last week, that an authoritative inquiry should be undertaken with the object of making recommendations to Parliament for dealing with the whole position of irregular practice in medicine and surgery had its origin in the above considerations. The motion was generally criticised in the House as an intention to make medical practice of any sort, save when carried on by qualified practitioners, illegal, and we regret that the debate should have been carried to its inconclusive termination on these lines. For we can conceive that the outcome of such an inquiry as was suggested might have led to a considerable clearing up of misunderstandings and removal of friction with perpetual repercussions. And, indeed, Mr. Neville Chamberlain's intervention in the discussion made this fairly clear, although he was unable to support Dr. Little's motion by his vote. The Minister of Health explained that he could not take any cognisance, from his official position as "General of the Army" of qualified doctors, of efficiency and discipline among those who are unqualified, but he suggested that what he termed "the irregular troops" might in certain cases render valuable public service, and that it would be wrong to prevent the public from deriving advantage from any skill in therapeutics that might be available. No one can hold any other opinion, but the practical problem remains of how to obtain evidence that the contributions to medicine of unqualified people possess the qualities vaunted for them.

Discussion open and free from animus between the public and the medical profession ought to make clear that scientific medicine is not afraid of competition, but must "refuse to coöperate"—to use a stereotyped reproach of doctors—when the principles of the systems of healing are without foundation, or when the claims made for the systems or the remedies cannot be submitted for trial or are based upon secret formulæ. Because a thing is not commonly known to the medical profession it need not be wrong, but it need not be right, and some of the critics of modern medicine might well be asked to remember this. And above all things it should be understood that the Medical Acts were framed for the public protection, so that the public should possess a fully educated medical service. This does not imply that all therapeutic wisdom must reside in that trained body of men and women, and that contributions to medicine from those without that body should be made illegal; Acts of Parliament with such a term of reference would lead to the imprisonment of all chemists, all physicists, all biologists, a vast group of mathematicians, and some philosophers. But it does imply that a standard of medical efficiency has been erected by the State, and that any form of State recognition, extended to persons who do not comply with the standard, must lead to confusion and public peril.

# THE SCOTTISH HOSPITALS.

In the summer of 1924 the Secretary for Scotland appointed the Hospital Services (Scotland) Committee, under the chairmanship of Lord Mackenzie, to inquire into the insufficiency of the hospital and auxiliary services north of the Tweed, and "to make recommendations for the development and maintenance of those services to meet the needs of the community." After thorough and painstaking inquiry and the hearing of much evidence, summarised from time to time in our columns, the Committee have now issued a report which, while it shows that the hospital needs of Scotland are relatively more considerable than those of England, is a complete vindication of the voluntary system The voluntary hospitals, the Committee declare, "have won and held a special place in the life of the community. They are capable of playing an equally important part in the future. Any interference with them which would tend to impair their voluntary character would be not only unpopular but thoroughly bad policy." Building upon this bed-rock of voluntaryism, the Committee explain, with clearness and cogency, how the hospital system of Scotland can be enlarged and coördinated with the highest degree of efficiency and the lowest degree of cost. The pressure upon the 131 voluntary hospitals in Scotland is severe and increasing. With an aggregate of 8589 beds, they treat in a year well over 110,000 in-patients and 360,000 out-patients. At the end of last year the waiting-lists of the six teaching hospitals contained nearly 6000 names, and although it is notorious that such lists cannot be taken quite at their face value they do, as a fact, represent a very serious state of things. "Overcrowding has come to be the normal condition of the large hospitals" and some of the smaller ones as well, and so acute is it that, notwithstanding the placing of beds in corridors, in some places "persons suffering from malignant diseases are not always able to obtain immediate admission." Throughout Scotland the insufficiency of beds for subacute and chronic medical illnesses is universal, and is especially marked in regard to maternity and children's beds. The deplorable housing conditions of Scotland are responsible for much of this pressure and for the creation of a vicious circle which prevents its reduction. In unsuitable surroundings the private practitioner can often do little, and a disease which, with reasonable facilities, might be cured in an early stage, goes on worsening until it becomes so acute that admission to hospital is imperative. The patient endures a long period of suffering, his health may be permanently ruined, or the right treatment may come too late. This is not only a tragedy for the sick man and his family, but adds to the sum of unnecessary suffering and preventable mortality.

The Committee's remedy for a situation, which must necessarily grow worse with the increase of population and of the tendency to resort to the hospitals in maternity cases, is the provision of 3600 additional beds and the coördination of the entire hospital system. This figure includes 1000 beds for maternity and the illnesses of children, 600 of which they think ought to be, and could be, provided by the local authorities, which would leave a round 3000 to be created by the voluntary institutions. They put the cost of this additional accommodation at £1,800,000, and propose that it should be equally divided between the hospitals and the State. In their view the provision of nearly a million of money is not beyond the resources of the Scottish voluntary hospitals which, broadly speaking, are in a satisfactory pecuniary position. In 1923, the last year for which complete figures were available, they had a surplus on ordinary income and expenditure of nearly a quarter of a million; extraordinary, or capital, expenditure was little more than a third of the extraordinary income; and their accumulated funds exceeded four millions and a quarter. This is not to say that hospitals with deficits are unknown, but the figures are a clear indication of the vitality of the voluntary principle. Neither the hospitals nor the State would be called upon to provide their quotas in a lump —the expenditure would necessarily be extended over a considerable period. Even in the present position of our finances the provision of something less than a million for a primary need of the national health, spread over a few years, would be no unconscionable burden, even when added to the money that has been asked for further accommodation in England. It is recognised, however, that the provision of a large number of new beds, necessary as it is, will not of itself place the hospital situation in Scotland upon a thoroughly satisfactory footing. Coöperation is needed between the voluntary hospitals and those maintained by public money. In the eyes of the Committee the Poor-law institutions stand completely condemned. In the whole of Scotland there are only three or four of them that would compare well, in staff, equipment, and service generally, with modern general hospitals. Their isolation from the main stream of hospital development involves loss to the patients, to medical teaching, and to the training of nurses. It is, therefore, not only urged that they should be transferred to the public health authorities, but that such transfer has become inevitable. The stigma of pauperism which attaches to them is felt so acutely that even the destitute resort to them with reluctance. On the other hand, the range of the public authority hospitals is constantly widening, although the law applicable to Scotland does not permit of the creation of municipal general hospitals covering the whole field of work such as the Bradford municipal hospital. In some respects accommodation in the public health hospitals is nearly, if not quite, adequate; in others it falls short, but once the health authorities were able to absorb the Poor-law infirmaries the way should be open to a fuller coöperation than has hitherto been possible.

The report contains a number of minor recommendations which, in the aggregate, are of considerable importance. The Committee favour the provision of separate wards or blocks in the general hospitals for paying patients; the exemption from legacy duty of bequests to hospitals; the further development of the principle of workmen's contributions; and —very far from least—the making of much more substantial contributions from national health insurance funds. In 1923, notwithstanding that at least one-third of the patients were insured persons, the health insurance contributions amounted to only 1·9 per cent. of the expenditure. The inadequacy of the assistance from these great funds has long been a sore subject with the voluntary hospitals which, in view of the extent of their services to the compulsorily insured, are clearly entitled to be helped on a much more liberal scale. The execution of the policy outlined by the Committee would require an increase in the income of the voluntary institutions of nearly £300,000 a year to cover the enhanced cost of maintenance, but the proved resiliency of the system is such that there need be little fear, especially with better insurance help, of its not being forthcoming. The valuable proposal is made that there should be a central hospitals commission for Scotland, and it is obvious that if three types of hospital are to be merged into two, and real coöperation established between them, a coördinating authority would be almost essential. The report, from which the only dissentient is the Labour member of the Committee, has been well received in Scotland, and will commend itself to the general sense of a people which, since the war, has become keenly alive to the growing importance of our hospital system and to the increasing dependence of the national health upon the maintenance of the system at the highest level. Money spent upon the extension and scientific equipment of hospitals is national health insurance in the most complete sense, and no weakening of the voluntary principle is implied in the State offering it a helping hand once in a way. The help that has already been given averted a serious crisis which would not only have involved heavy loss to the Exchequer, but a still more disastrous loss in the moral and spiritual sphere. The voluntary system, thus helped over the stile, has been going forward with increased strength ever since

# THE NATURE OF TUMOUR FORMATION.

THE results of Dr. G. W. NICHOLSON's laborious histological investigations upon tumour formation and the conclusions he has drawn from many researches already published in *Guy's Hospital Reports* and elsewhere, are embodied in the Erasmus Wilson lectures delivered before the Royal College of Surgeons of England last year, and now published in book form.[1] In the first lecture he considers the structure and functions of tumours and arrives at the conclusion that they are essentially parts of the tissues of the body, showing no fundamental difference functionally or anatomically from normal tissues. He draws attention to the dictum of E. SCHWALBE—that the gradation from uniovular twins on the one side, through acardiac and parasitic foetuses, certain monsters, teratomata, complex mixed tumours, to the simplest and most highly malignant neoplasms on the other, is so fine as to be almost imperceptible—and holds that this circumstance refutes the pretentions of every kind of parasitic theory to explain tumour formation in general. In the second lecture tissue malformations are considered under the headings of "acquired" and "developmental." Many examples are discussed, including such conditions as the metaplasia of epithelial surfaces in chronic inflammatory conditions and the nodules of ectopic pancreas frequently found in various situations. Dr. NICHOLSON concludes that acquired tissue malformations are the normal reactions of the cells to an abnormal environment. As regards developmental malformations, such as nodules of ectopic tissue, he finds that they represent mature tissues showing no predilection to grow beyond strictly physiological limits, and "give no support to the thesis that they tend to assume blastomatous characters and become the effective cause of tumour formation." In the last lecture, dealing with the sequence of events in tumour formation, he analyses the development of a fibro-adenoma of the breast, and studies a specimen of an embryonic tumour of the kidney in which could be traced the formation of tumour masses from developing glomerular tufts. The occurrence of such embryonic tumours he holds to be one of the few instances of tumour formation from embryonic cell-rests in accordance with COHNHEIM's theory; even where a tumour has apparently developed from a cell-rest he finds no evidence that the cells of such a rest were from the first more disposed to tumour formation, but believes rather that some anomaly of environment to which they were subjected at an early stage of their life-history has prevented their normal differentiation

The main question that the author seeks to answer is, "Must we believe that tumours always originate in cells that are abnormal—that are afflicted with a *vitium primæ formationis*—or are they simply the expression of one of the physiological potencies of every perfectly healthy cell in the body?" He finds no satisfactory reason for adopting the former view, but is led by his researches to believe that tumour formation is the physiological reaction of primarily normal cells to a changed environment. As regards the change of environment necessary to produce tumour formation, the question of parasites is considered. Dr NICHOLSON states that he is in sympathy with those who assume that a parasite is not present in all tumours, but only in malignant ones. To contend that every tumour harbours a parasite would, in his view, be equivalent to saying that all growth must be the result of parasitic action. In view of the recent experimental evidence in favour of a parasite in malignant tumours his conclusions are of particular interest, since they were arrived at independently and from a purely histological standpoint.

The evidence available at the present time certainly indicates that the environmental change to which the cells are subjected is the major factor in the production of the majority of tumours, and normal cells can undoubtedly be stimulated to tumour formation by suitable experimental procedures. We cannot, however, ignore the question of the predisposition of the cells of certain individuals to react more readily to tumour-producing factors. Complete uniformity in this respect amongst normal individuals or the normal cells of such individuals is not to be expected. The question remains, however, whether the normal variations are of such a degree as to become an effective factor in producing either an immunity or a susceptibility to tumour formation in certain individuals or groups of individuals. The extensive studies of MAUD SLYE[2] on the inheritance of spontaneous tumours in mice show not only that the tendency to tumour production is inherited, but that it follows strict Mendelian laws and can be demonstrated as a recessive character with almost the same precision as can such an obvious character as albinism. This worker has bred strains of mice showing, on the one hand, the development of spontaneous tumours in 100 per cent. of cases, and on the other the absence of such a tumour in 15 generations; she also produces evidence that the site and characters of the tumours can be influenced in the same manner. In view of such evidence, while admitting that the cell environment is probably the determining factor in tumour production, one can hardly dismiss from consideration inherited hypersusceptibility of the individual or of certain organs or parts of organs.

JOINT TUBERCULOSIS COUNCIL POST GRADUATE COURSES ON TUBERCULOSIS.—Dr S. Lyle Cummins, David Davies professor of tuberculosis, Welsh National Medical School, principal medical officer, Welsh National Memorial Association, will hold an intensive post-graduate course on tuberculosis, commencing April 12th next and ending April 17th, for medical men and women specially engaged in tuberculosis work. The course will consist of clinical meetings with demonstrations of medical and surgical cases at Glan Ely Hospital, Fairwater, near Cardiff, and at Cefn Mably Hospital, near Cardiff; X ray demonstration and reading of films at Glan Ely Hospital, Fairwater; daily lectures and daily pathological demonstrations at the Welsh National School of Medicine, Cardiff. The names of those wishing to attend should be sent as early as possible to the Hon. Secretary, Joint Tuberculosis Council Post-Graduate Courses, at 19, Brunswick-square, Camberwell, London, S.E. 5 ('phone Hop. 1100), from whom particulars can be obtained.

"Ne quid nimis."

## THE SCIENCE OF VENTILATION.

MUCH attention has been given recently to a study of the comfort and welfare of industrial workers, particularly with regard to the atmospheric conditions necessary to promote health and efficiency. Researches under the control of the Medical Research Council and the Industrial Fatigue Board have illumined many problems of profound importance to national health, and the results have revolutionised our ideas in many directions. The trend of thought dominating the literature on the subject has centred round one particular instrument—viz., the katathermometer, the introduction of which, by Dr. Leonard Hill, marked an epoch in the science of ventilation. Much independent evidence has been brought forward of the value of the katathermometer in detecting errors in ventilation; and, although some have attempted to indicate where the instrument fails, it has become increasingly evident that no other single instrument combines so well the two variables of temperature and air velocity. Indeed, Dr. H. M. Vernon and Mr. T. Bedford, in Part III. of the report[1] just issued, show that the correlation of cooling power, as determined by the katathermometer, on air sensations—stagnancy or freshness—is 0·703 in summer and 0·790 in winter. Apart from such evidence of the value of the instrument, its chief success lies in the marked stimulus it has given to research in the problems of ventilation, not only in Great Britain but all over the world, in the United States of America, in Germany, and in Japan.

As investigator to the Industrial Fatigue Board, Dr. Vernon has initiated several lines of research in Great Britain, and the present report contains four valuable studies. In Part I. Dr. Vernon and Mr. J. J. Manley describe two new instruments designed for measurements of variations: (*a*) in the velocity, and (*b*) in the temperature of air currents. For the former purpose a new form of hot-wire anemometer was constructed, being calibrated by the katathermometer. This anemometer is very sensitive to changes of air velocity, whilst little influenced by changes in air temperature. For the study of changes in temperature a suitable thermopile was devised, which was unaffected by changes in velocity. In Part II., for which Dr. Vernon is alone responsible, we are informed that the katathermometer "factor" varies with the temperature. The necessary corrections over a wide range have been determined and will allow the low air velocities found in an ordinary room to be measured with far greater accuracy. In Part III. Dr. Vernon and Mr. Bedford (assisted by Mr. C. G. Warner) prove that to produce a given sensation of air movement in winter required a cooling power about one unit higher than that required in summer. This was due to acclimatisation and the mean cooling power (in relation to a given sensation) was found to change gradually from month to month as the mean temperature changed. A considerable allowance has thus to be made for acclimatisation; if a cooling power of 6 is reasonable during mild weather, one of 5 may be equally reasonable during hot weather, and one of 7 during cold weather. The effects of oscillations in air movement and temperature also were explored by means of the specially designed instruments already mentioned. It was found that whilst the sensation of air movement was apparently increased by increasing the oscillations of air velocity, no clear proof was obtained of its increase by oscillations of temperature.

The concluding section of the report records a series of careful and patient observations by Dr. Vernon upon himself, which indicate that in order to induce an actual cooling of the overheated body of a man engaged in hot and heavy work, it is of most importance to reduce the temperature, and next in importance to reduce the clothing, whilst an increase of air velocity has but little effect; however, if the body be naked or only clothed in vest and trousers, the effect of moving air on the cooling-rate is considerably greater than when the body is more warmly clothed. Observations made in a new wind tunnel at the National Institute for Medical Research have, we understand, shown that if the velocity is great enough to drive air through the clothes, and so ventilate the clothing, velocity has a very great effect on the comfort of the warmly clad man. These results extend those given by Dr. Vernon for his step-climbing experiments.

## ECZEMA AND URTICARIA.

A RECENT discussion at the Royal Society of Medicine[1] showed how obscure the problem of eczema still is. The term eczema does not even describe a recognised clinical entity; originally restricted to a watery eruption of the skin, it has been expanded to cover almost any form of skin trouble of unknown origin, and the various schools differ so widely in their definitions of clinical eczema that, for practical purposes, each observer recognises his own particular variety and no other. Osler's text-book contains no definition of eczema. Obviously the whole problem needs restating, and the authority who attempts this must clear the ground at the clinical end before he proceeds further. Dr. Erwin Pulay's monograph, "Ekzem und Urticaria"[2] is a summary of the most recent work in this branch of dermatology, and deals comprehensively and impartially with the leading theories of the causation of the manifold types of reaction that are classed as eczematous. The key-symptom he holds to be the characteristic irritating itch, but the watery nodules which Blaschko and others regard as pathognomonic he does not consider inseparable from eczema. Many forms of undoubted eczema do not show them and they are conspicuous in many conditions, such as impetigo and the pemphigus group, that are completely distinct from eczema. He draws freely on the results of Weidenfeld, and quotes his classification into the three groups of anæmic, seborrhœic, and psoriatic eczema. The second of these is by far the most frequent type and presents the clearest symptoms, which do not include the formation of watery nodules. It results from a peculiar constitutional condition of the skin and is often associated with alimentary disorders. The third division is the protean dermatitis by which eczema manifests itself in psoriatic subjects.

Eczema is a definite clinical skin reaction that requires two factors for its production—an exciting agency and a diathesis. All efforts to reduce it to a single ætiological formula have, however, failed, especially the parasitic theory of Unna. Both its precipitant and its diathesis vary with the individual, and some eczema subjects respond to all kinds of skin irritants and some only to one. The latter are probably always victims of an anaphylaxis, and their reaction is an antigenic defence. The physiological basis of every eczema is an abnormal sensitivity both of the skin and of the nerve-endings; that of the latter can be caused by almost any lack of metabolic, endocrine or nervous balance, and that of the former by external irritation, which will have more effect on some skins than on others. This may explain the frequent liability to eczema of persons with a "rheumatic" diathesis. One form is undoubtedly scorbutic and yields to treatment by vitamin C. Urticaria is distinct from eczema, and is founded on a constitutional or anaphylactic sensitivity of the capillary vessels. An internal excitant will produce urticaria if the capillaries are sensitive, and non-eczematous dermatitis if the epidermic cells are sensitive; if the sensitivity is in the nerve-endings it will give pruritus and, if the epidermis is sensitive, as it is when subject to external irritation, it will give eczema. Both urticaria and eczema can be hæmatogenous, but eczema only on a site where it has appeared before. The excitant of primary eczema is nearly always scratching of the parts where the nerve-endings are excited. Pruritus is always a part of the clinical picture of eczema, and its origin is usually endogenous; it may, however, be caused by lice, scabies, or local infectious conditions, and may develop into eczema if the skin is injured mechanically. Idiosyncratic eczema and urticaria are comparatively rare. They appear only when one particular organ or system is excited, and are distinguished thereby from the anaphylactic manifestations, with their attendant eosinophilia and general vagotonic symptoms.

Whether or not eczema and urticaria are curable depends, in Dr. Pulay's view, on whether or not they have caused irreversible changes in the cell-albumin. The fixation of an adaptive change, and so the perpetuation of each step forward in evolution, is effected by an irreversible change in this substance and, if a pathological process continues long enough, the cells cannot recover their normal function. The conditions of physiological life give ample scope for reversibility and a minimum opportunity for any process to become fixed. No physiological change occurs, however, without some alteration in the composition of the cell-proteins, and the mechanism of the eczema reaction will have ultimately to be solved by the colloid chemists.

## ANTIRABIC INOCULATION.

THE strict Pasteurian method of inoculation with rabbits' spinal cord, dried for varying periods and believed to contain a truly attenuated as opposed to a partially destroyed or merely diluted virus, has been superseded in India by the use of a vaccine killed with carbolic acid. This innovation was originally due to the work of Fermi begun some 20 years ago. The method was reinvestigated by Semple in India in 1911 and has been approved by Harvey and McKendrick. It was adopted at the Kasauli Institute in 1912 in place of the dilution method of Hoegyes which had been used there since 1907. The report[1] by Dr. G. Stuart and Dr. K. S. Krikorian for the two years ending April 30th, 1925, on Antirabic Procedure in Palestine, records the treatment with carbolised vaccine of 1020 persons with 0·82 per cent. mortality. Of these, 420 were presumably at risk and their death-rate was 1·47 per cent. The preparation used is a 2 per cent. emulsion in distilled water of brain from a rabbit dying of rabies on the ninth day after inoculation with fixed virus. To this is added 1 per cent. phenol and it is then kept at 37° C. for 24 hours, and subsequently diluted with an equal quantity of salt solution and stored in the ice-chest. Its efficacy is considered to remain unimpaired for three months, after which period the stock is renewed. In the first of the two years the above vaccine was diluted further with an equal quantity of saline before inoculation, but since May, 1924, the full strength of 1 per cent. brain material has been used. The virus in such a vaccine is apparently quite dead since large doses to rabbits and eventually to man in the course of treatment do not infect. In all cases of exposure to infection a dose of 5 c.cm. is given daily for 14 days, 2·5 c.cm being inoculated subcutaneously on either side of the abdomen. The advantages claimed for the method are efficacy, safety, cheapness, simplicity of manufacture, the good keeping qualities of the vaccine, the ease with which it may be distributed, and the consequent accessibility of the treatment. Experiments on rabbits and the clinical results demonstrate its harmlessness, and further experimental evidence is adduced that the preparation will, in some instances, but by no means always, protect rabbits against large doses inoculated subdurally. Evidence of the prophylactic power of carbolised rabies virus has also been brought forward by Kondo, and recently Schlingmann has given details[2] of experiments in which a single dose of a similar vaccine given subcutaneously protected dogs against 5 to 200 infective doses given subdurally 21 days later. These results should encourage further search for a yet more potent dead vaccine.

## SANOCRYSIN TREATMENT IN BERLIN.

THIRTY-FIVE years have passed since Koch made his first report on tuberculin. Older physicians remember very well the rush of patients from every part of the world to Berlin for a cure by the new remedy, and the disappointment which followed for those who had spent their last savings on that journey. Since then there has been a good deal of scepticism when new treatments for tuberculosis are announced, and sanocrysin, like other remedies, has been received with reserve in Berlin, as our correspondent there informs us. For the examination of the new compound a committee was formed, consisting of Prof. F. Neufeld, head of the Robert Koch Institute; Prof. F. Kraus, ordinary professor of medicine and head of the medical clinic in the Charité Hospital; Prof. A. Czerny, head of the university clinic for children's diseases; and Prof. U. Friedemann, head of the department for infectious diseases in the Virchow Hospital. After experiments carried out on animals, Prof. Neufeld came to the conclusion that against strains of tubercle bacilli more virulent than those obviously used by Prof. H. Møllgaard, the results were not so favourable. He is of opinion that a curative effect may be obtained when the tubercle bacilli are easily accessible to the compound; but this is not as a general rule possible in human beings where the tuberculous centres are surrounded by a thick wall of tissue. In the clinical test albuminuria was sometimes observed after the administration of the compound, when the dose was too large; and the reaction varied very much in different patients. Only serious cases, in which other remedies had failed, were selected for trial, and this rule was especially kept in the case of children, in whom slight infections often clear up without any special treatment. Twelve children were attended by Prof. Czerny, of whom three suffered from tuberculous meningitis and three from miliary tuberculosis. They were chosen because their tuberculosis was certainly not of old standing and was therefore suitable for sanocrysin treatment. Only one of them is still alive, and he is not in good health. It seemed that in children the compound had a rather unsatisfactory influence on the course of the illness, although no definite judgment could be given. In the clinic of Prof. Kraus the remedy was administered in nine cases; three of them died, one was not improved, and in one the administration had to be interrupted. In four cases, however, a considerable improvement was obtained. It is remarkable that the cases which improved were of an aggravated kind, and had not profited from other treatment. In the Virchow Hospital 54 cases were treated by sanocrysin. In some of them the fever ceased, the weight increased, and the state of the lungs became more satisfactory. The discharge diminished, and in seven of the cases the tubercle bacilli disappeared. The patients of the Virchow Hospital belong mostly to the poorer classes, and sometimes improve without any special treatment other than the better care and food they got in hospital; but the administration of sanocrysin had a marked influence in 10 out of the 54. According to Prof. Friedemann it is worth while to administer sanocrysin, although it cannot yet be described as the remedy for tuberculosis. The committee came to the conclusion that the compound ought not to be tried outside hospitals, because its dangers are not yet fully ascertained; that certain patients show an idiosyncrasy to it; that the first doses should not exceed 0·25 g.; that the intervals ought not to be made too short; that fresh exudative cases are the most suitable for the treatment; and that it might be administered in hæmoptysis to prevent the bacilli spreading throughout the lungs.

## THE CLASSIFICATION OF MENTAL DISEASE.

IF the classification of physical disease is obscure, it is not surprising that that of mental disease should be almost inchoate. Mental disease is a reaction of the whole personality and, in the words of Bianchi, "as a sphere with various designs made to revolve on different axes presents a new aspect at every turn, so the field of the mental affections presents a different picture on every classification." These designs never correspond, and a classification made from one aspect only will be stultified by one made from another equally vital aspect. A purely ætiological distinction is useless, because the same cause will produce completely different results in two different individuals. The bases of pathology and anatomy on which all classification is founded in general medicine will only support a very small part of the structure that has to be built out of a great and at present almost unrelated mass of clinical material. There is no doubt that patient research will enlarge this basis. Possibly in fullness of time it may become large enough to support the whole structure. Meanwhile, however, psychiatrists need a common classification to enable them to work together, and students need one to give them landmarks by which they may direct their study with a minimum of confusion. A survey of the current text-books on psychiatry makes it appear at first sight that the classificatory schemes used by different authorities have very little in common, but a closer scrutiny will show that, thanks chiefly to Kraepelin, they nearly all recognise three main groups of mental affection. The first includes those due to an evolutionary psycho-cerebral defect, the second those caused by infective, autotoxic, and toxic agents in properly evolved individuals, and the third those with an organic basis, a diffused or localised pathological lesion of the brain. This scheme is, in its beginning, ætiological, and it is obvious that these divisions are by no means water-tight compartments and that many conditions are common to two if not to all of them. An idiot is as liable to a psychosis of toxic origin as a fully evolved person, and evolutionary defects of the brain are very often due to organic lesions such as those caused by inherited syphilis and the traumata that occur during parturition or the early years of life. Nevertheless, whatever may be the clinical picture, the criterion upon which each of the groups is based is the most prominent feature of the condition, and this broad division is not incompatible with the clinical criterion that must govern both the skeleton and the details of a true classification.

Dr. C. C. Easterbrook, in his Morison lectures for 1925, which have just been reprinted in book form,[1] has put forward a classification based on 20 years' intensive study not only of the clinical condition of mental invalids, but also of their family history, their past bodily and mental history and environment, and often their after-history or post-mortem pathology. He classes the psychoses under the five headings of Congenital, Constitutional, Organic, Organismal or "Bodily," and Toxic and Energic. The first group deals with the various forms of amentia, the second with the biogenic psychoses, and the psycho-neuroses from which psychosis develops. The third group contains the psychoses due to sclerosis, to cerebral tumour, hæmorrhage, embolism, &c., to cerebral syphilis, and to other gross nervous lesions. The fourth group are those caused by infections and associated with physical disease, and the fifth contains the psychoses resulting from exogenous poisons and traumata. One disadvantage of this classification is that it does not recognise the essential similarity between all the psychoses of toxic origin, whether the toxin is endogenous or exogenous. The common factor between them is the biological defence mechanism of confusion, clearly one instance out of many in which the clinical consideration far outweighs the ætiological. For this reason his fifth group seems to be unnecessary; the psychoses due to poisoning by drugs or chemicals would be better classified in a general toxic group, and those due to trauma are allied both ætiologically and clinically with other psychoses of organic origin. It is also very doubtful whether the psychoses developed in association with many physical disorders have any clinical connexion with the physical disorder at all. Sir Maurice Craig devotes a special chapter in his "Psychological Medicine" to these secondary mental disturbances, and points out that very few physical disorders, other than the infective states, exert nearly so much influence on the form of the accompanying psychosis as does the patient's own constitution. If they have any common factor it is more probably that recently noted by Freud in his theory of "pathoneurosis"—i.e., the tendency of any physical disorder to produce a psychotic reaction by attacking the self-regarding sentiment. This would place them in the biogenic group.

It would be easy to multiply criticism of an individual classification, and it is a merit of Dr. Easterbrook's that it contains many points which challenge accepted thought. Complete success is unlikely to attend any attempt at detailed classification of mental diseases until pathologists supply us with the essential data. In the meantime we may have to be content with the broad outlines of Kraepelin's scheme, determining the details by the factor which he rightly held to outweigh all others—namely, the clinical.

## SPIRITUAL HEALING AND MODERN MEDICINE.

THE paper read by Dr. F. G. Crookshank on this subject at a meeting of the Hunterian Society, when various ecclesiastical authorities took part in the debate, was reported in abstract in THE LANCET of Nov. 14th, 1925. The paper is now published in full in *Psyche* for January, 1926, and may therefore be studied by those who are interested in the subject and who found in the abbreviated version of his words an invitation to closer study. We shall not, we think, misinterpret his position if we say that he is greatly concerned with what is, nowadays, generally agreed to be of vital importance—namely, the problem of the relations between science and philosophy, or metaphysics. He holds, indeed, that the general neglect in medicine of first principles has led many to declare that all considerations of a metaphysical nature are vain at the very moment that they themselves base their theories and beliefs on a form of metaphysics all the more dangerous because not recognised. Medical men who are materialists in metaphysics and realists in logic do come, almost insensibly, to ignore the importance of phenomena that they cannot "explain" in terms of their own prejudices, and so to despise the observations of others who do seek, honestly, to "explain," in terms of idealism or religion, phenomena that have been the subject of attention throughout the centuries. It is, perhaps, time that in medicine there was some change of orientation. As Dr. Crookshank suggests, so long as the dog and cat know when and where to seek the grass they eat when ill, and so long as this knowledge is "unexplained," it cannot be said that the healing art is entirely comprised by a knowledge of physical signs and post-mortem appearances. The antithesis between the functional and the organic case of disease still, perhaps, dominates too much orthodox teaching, but cases are now restored to health as a result of treatment involving recognition of the predominance of the spiritual or mental factor, which, a few years ago, might have been subjected to a routine of operative interference sometimes unnecessary and often futile. Dr. Crookshank suggests that recognition of the importance of the spiritual factor may come about, in these latter days, as a result of the attention now being paid to the tenets of psycho-analysis, and that ideal, of course, lies behind the intelligent part of the support extended to this teaching. And, in this connexion, it is worth while calling attention to the synthetic work of Blondel (too little known in this country) wherein it is attempted to reconcile the points of view of Freud, of Jung, of Adler, and of the Church by the adoption of a formula which implies the origin of every "conflict" in "la conscience morbide." Dr. Crookshank writes with clearness and learning on matters whose difficulty calls for just those qualities if they are to be dealt with in any useful manner.

## IMPAIRED RENAL FUNCTION.

THE investigation of early renal disease and of minor degrees of renal deficiency has received considerable impetus in recent years from the introduction of more perfect methods of chemical investigation. Whether these methods have led to marked improvement in early diagnosis and increased accuracy in prognosis is more questionable. Even now, unhappily, the methods in use only give information when the renal damage has already become extensive. It has been estimated that a faint trace of albumin in the urine at the age of 40 or over represents a death-rate from nephritis ten times higher than the normal, a trace increases this rate to 30 times the normal, whilst with large amounts plus casts the rate is about 50 times the normal. Every physician has seen amongst his patients cases with a trace of albuminuria, associated with a normal blood pressure, in whom blood analysis and such tests as the urea-concentration test proved indecisive, when, nevertheless, uræmia or fatal arterial changes followed in a surprisingly short period. It would seem that neither the clinic nor the laboratory can yet give us the information we require concerning these cases. An interesting investigation with a view to improving our knowledge in this direction has been recently published by Dr. Nellis B. Foster,[1] of New York. In nine patients who had had one kidney removed he carried out very complete tests. The patients selected were all under 40 years of age, without signs of disease in the remaining kidney, and the inquiry was in each case undertaken within three weeks of the removal of a diseased kidney. In this way it was hoped to exclude kidneys with changes due to disease or senility and also without suspicion of compensatory hypertrophy; but as tuberculous disease in the remaining kidney can never be wholly ruled out, Dr. Foster rightly stresses the results given in these cases where the trouble for which nephrectomy had been performed was not tuberculous. The tests chosen were, first, Volhard's water-excretion test, consisting in the administration of 1500 c.cm. of water drunk in half an hour before breakfast, a total excretion of at least a litre during the following four hours being considered necessary to establish normality; secondly, the patients were for 24 hours given an ordinary diet without any fluids—that is, neither drinks nor soups of any kind—but otherwise a normal diet. In such circumstances a normal man will at the end of the test period usually void urine of a specific gravity of 1030 or higher; in the nephrectomised cases only one case yielded a urine of such density as to be considered absolutely normal. The third test employed was that of ascertaining the ratio (urea in one hour's urine) ÷ (urea in 100 c.cm. of blood) which, according to Addis and Drury,[2] averages 50 and should not fall below 34 in normal persons even when the urea in the blood has been artificially increased. The cases investigated by Dr. Foster were given 30 g. of urea in a litre of water before the test, and it was then found that in every case the ratio given fell below Addis's standard of normality. In cases where the test was repeated at a later date the result indicated a considerable return towards the normal, a result which points either to some hypertrophy of the remaining kidney or to the kidney having suffered some toxic depression at the time of the original test. Reviewing the results as a whole, the author feels that the demonstration of renal deficiency in persons with only one kidney is only doubtfully revealed by these tests, the ratio after giving urea being the only test pointing at all consistently to any limitation of kidney function.

## THE DEFENCE OF EXPERIMENTAL MEDICINE.

AN account of the history of the Research Defence Society, founded 18 years ago, is given in the current number of the organ[1] of the Society, and may be recalled for the benefit of those of our readers to whom the story is not familiar. It arose out of a committee organised by Prof. E. H. Starling to collect evidence for the Royal Commission on Vivisection. When all the evidence had been set out and published, enthusiasts such as Mr. Stephen Paget were not prepared to let good machinery be broken up. A society was formed in order to bring about a better understanding of the value of medical research, and to expose false statements made with the object of limiting and hindering those animal experiments on which its progress so largely depends. The Society throve progressively during the first six years of its life, and in 1914 numbered over 5000 members and associates. The war years demonstrated the value of prophylactic methods in protecting whole armies from disease, and broke down much of the prejudice against the use of experimental animals for the production of sera, for the standardisation of biological products, or for the testing of remedies. While the objects of the Society were thus being realised, its membership decreased and during the war its activities were necessarily curtailed. A revival of these appears to be taking place, for three debates are reported in the January issue of the journal. Probably a better method of propaganda also employed by the Society is the popular lecture, because the public are eager to learn of new discoveries in medical science even when these have no immediate bearing on prevention or treatment of a specific disease. The modern doctor tends to take for granted the need for observations on animals and sometimes neglects to equip himself to meet the arguments still advanced against them. The Research Defence Society exists to uphold and defend experimental medicine and ought to have a membership as wide as the Medical Register.

## NEOPLASMS OF THE TESTICLE.

SINCE the classic paper of Wilms in 1896, it has been generally recognised that the mixed tumours of the testicle are teratomata. Data have slowly accumulated to show that, with the single exception of the rare testicular "dermoid," the teratomata of the testicle are extremely malignant, and this malignancy has been held to be a carcinomatous or sarcomatous degeneration of a previously benign tumour. From the study of some 95 tumours of the testicle, Mr. H. W. B. Cairns, first surgical assistant at the London Hospital, has decided that this view is incorrect. Primary tumour and its metastases, he states, exhibit the same remarkable power of differentiating to form histologically benign tissues, exactly similar in structure to the tissues of the normal fœtus. The teratoma retains its biological characters in its metastases and is, therefore, inherently malignant. Mr. Cairns laid his conclusions before the Royal College of Surgeons in a Hunterian lecture on Feb. 12th. The series of cases he has collected is unusually large and the opinions formed are of corresponding importance. Only three cases of true hypertrophy of the breast accompanying tumours of the testicle have previously been recorded; Mr. Cairns's series contains another three. This hypertrophy is of interest as an indication of the fœtal nature of teratomata of the testicle; further evidence is afforded by the occasional discovery of chorionic remnants in the tumours. Considerable controversy has raged over the nature of the common spheroidal-celled tumour of the testis, variously described as alveolar sarcoma, carcinoma, or séminome. In 1911 Ewing claimed that this tumour was teratomatous, but his view has not been generally accepted either in this country or in France. The London Hospital cases, however, provide overwhelming evidence that the spheroidal-celled tumour belongs to the teratoma group. Cells morphologically identical with the spheroidal cells are found in great profusion in almost every teratoma of the testis; and tumours occur which are, even to the naked eye, mixtures of teratoma and spheroidal-celled tumour. The exact position of the spheroidal-celled tumour in the teratoma group is not quite clear. Ewing has contended that the spheroidal-celled tumour is formed by overgrowth of one element of a pre-existing teratoma, but his view receives no support from this series of cases. On the contrary, the evidence from the London Hospital suggests that the cells of the spheroidal-celled tumour are totipotent and that they arise in the seminiferous tubules. Mr. Cairns's series throws suggestive light on the much-discussed relationship of injury to tumours of the testicle. He considers it highly probable that the part played by injury is not to initiate the neoplastic process, but rather to stimulate the more rapid growth of a pre-existing but hitherto unobserved tumour. Approximately one-third of the cases are cured by operation, and the London Hospital figures are slightly favourable to the radical operation as compared with the more simple operation of orchidectomy. We propose to publish Mr. Cairns's interesting lecture in a later issue.

[1] *The Fight against Disease.* Macmillan. 6d.

THE Royal College of Physicians of London has issued the following programme of memorial lectures. They will be held during the spring on Tuesdays and Thursdays at 5 P.M., and any member of the medical profession will be admitted on presentation of a visiting card. Prof. W. W. C. Topley will deliver the Milroy Lectures on March 2nd, 4th, and 9th, and has chosen Experimental Epidemiology as his subject. Dr. Bernard Hart will follow on March 11th, 16th, and 18th with Goulstonian Lectures on the Development of Psychopathology and its Place in Medicine; whilst on March 23rd, 25th, and 30th Sir Thomas Horder will deal with Endocarditis in his Lumleian Lectures. None will be held in April, but on May 4th and 6th Prof. Hugh MacLean will give two Oliver-Sharpey Lectures on Carbohydrate Metabolism in Health and Disease, and on June 8th, 10th, 15th, and 17th Sir Thomas Lewis will describe in four Croonian Lectures his Observations upon Blood vessels of the Human Skin.

THE memorandum addressed to the Ministry of Health by Sir George Newman in July, 1924, on Public Education in Health, has been reprinted, the demand for it having been exceptional. No alterations of substance have been made to the pamphlet, which we have abstracted (THE LANCET, 1924, ii., 671), but the information has been brought up to date, and reference is made to that section of the Public Health Act (1925) which empowers local authorities to undertake health education by means of the publication of information, the delivery of lectures, and the display of pictures. The subjects of tuberculosis, venereal diseases, and infant welfare have perhaps received the most organised attention on the part of local authorities, but many other aspects of public health have also been the subject of propaganda. These include cleanliness, domestic sanitation, the prevention of infectious disease, and the hygiene of childhood. Sir George Newman notes the just claim made by medical officers of health that their annual reports are a form of propaganda work which is not sufficiently read and appreciated by the public. These official reports, of which prescribed statistics and routine tabulations form only a part, afford opportunities of guiding the local authority and the public and are readable and informative documents, to which we are constantly calling attention.

## CLXI.

## THE TREATMENT OF CHRONIC TONSILLITIS.

### I. CHOICE OF METHODS IN CHRONIC TONSILLITIS.[1]

THERE are two types of tonsil: (*a*) The pedunculated, in which the space between the pillars of the fauces is wide and the fold of mucous membrane passing from the anterior pillar on to the tonsil is poorly developed, so that a large part or even the whole of the medial aspect of the tonsil is exposed. (*b*) The embedded tonsil, in which the opening between the pillars is narrow and the plica is well developed, so that only the lower portion of the inner surface is exposed. This type of tonsil appears small on first inspection and it is only when the patient is made to gag and the tonsil is outlined through the palate that its true size becomes apparent. The efferent lymphatics of the tonsil pass to the jugulo-digastric or tonsillar gland, which lies just behind the angle of the mandible.

### *Physiology.*

The faucial tonsils form part of the lymphatic ring which guards the entrance to the alimentary and lower respiratory tracts. In the germinal centres lymphocytes are formed and some of them migrate through the epithelial lining into the crypts and act as phagocytes. Adam compares the tonsil to a sponge which is "wrung" by the contraction of the surrounding muscles during the act of swallowing. When the muscles relax the tonsillar sponge takes up some of the fluid and bacteria from the mouth. The tonsils are most active in early life and form a first line of defence against the invasion of infectious disease. The crypts probably act as culture tubes from which toxins are absorbed so that the tonsils may be regarded as organs producing active immunity —i.e., as the vaccine laboratories of nature (Digby). When the tonsils are themselves diseased they no longer act as defensive organs but are a source of danger. If, as some have supposed, the tonsil had an internal secretion, we should expect that the ill-effects of enucleation would long ago have become manifest, but this has not been the case.

### *Pathology.*

Medical examination has shown that in this country from 6–10 per cent. of school-children suffer from such hypertrophy of the tonsils as to necessitate enucleation. Hypertrophy and sepsis are commonly associated (Brown Kelly). Attention to the hygiene of the mouth and teeth has, however, a beneficial effect on tonsillar enlargement. Infection may be limited to the surface or may spread beneath the epithelium of the crypts (lacunar tonsillitis). The capsule may be penetrated and an abscess may arise in the peritonsillar space above and lateral to the tonsil. In many cases the tonsil trouble is found to date from an attack of diphtheria, measles, or scarlatina; indeed, many regard scarlatina as a streptococcal blood infection, the tonsil being the main or only point of entrance. Rheumatic fever is often preceded by tonsillitis and the streptococci of rheumatism have been recovered from the tonsil and, on inoculation into rabbits, have produced endocarditis. Chorea has also been associated with tonsillar infection. The circulating virus selects a certain tissue for its growth, probably as a result of sensitisation (Brown Kelly). Newkirk rightly points out that many people have marked pyorrhœa or grossly infected tonsils and yet live to a ripe old age. All depends on the patient's power of resistance.

---

[1] An article in this series by Mr. Fraser on Tonsillectomy in Adults and Children will appear next week.

### *Bacteriology.*

The following organisms have been found on bacteriological examination of the tonsils (Wall): streptococci, 90 per cent. (these organisms are the cause of lacunar tonsillitis and peritonsillar abscess); *Micrococcus catarrhalis*, 94 per cent.; *Staphylococcus aureus*, 60 per cent.; pneumococci, 50 per cent.; diphtheroids, 30 per cent.; *B. influenzæ*, 18 per cent.; *B. coli*, 8 per cent. When hypertrophy is the indication for enucleation, less than 1 per cent. of tonsils show tuberculosis, but when the cervical glands are markedly enlarged, 38 per cent. are tuberculous (Carmichael). Mitchell has shown the close connexion in Edinburgh between tuberculous milk and tuberculosis of the tonsils and cervical lymph glands. He finds that 88 per cent. of cases of tuberculous cervical adenitis are due to infection spreading from the tonsil. In these cases the tonsils themselves are frequently normal in appearance.

### *Local Indications for Enucleation.*

These include: (1) Frequent attacks of tonsillitis. (2) Peritonsillar abscess; some surgeons recommend enucleation in the presence of such an abscess in spite of the difficulty of getting the patient's mouth open widely and the risk of excessive hæmorrhage. They point out that only one operation is required, that the abscess is most efficiently drained by enucleation, and that the dissection has already been partially accomplished by the abscess formation. It is better, however, to wait till the "quinsy" has subsided. (3) Great enlargement causing obstruction to respiration and swallowing. (4) Well-marked enlargement of the cervical glands which does not subside after an attack of tonsillitis. (In many of these cases of apparently "acute" adenitis the condition is really tuberculous.) The fact that the jugulo-digastric gland can just be palpated is not sufficient indication for tonsillectomy, as this condition is present in the majority of children. (5) Tuberculous cervical adenitis, involving the tonsillar and neighbouring glands. (6) The presence of pus or foul-smelling material in the tonsil crypts. In such cases there is, as a rule, marked congestion of the anterior faucial pillars. The condition of the tonsil crypts may be ascertained by pressing on the palate lateral to the tonsil with Tilley's instrument or by employing a cup-shaped glass suction tube fitted with a rubber bulb. The fact that a little cheesy material can be squeezed out of the crypts on pressure is not sufficient indication for enucleation, as this condition is found in from 30 to 50 per cent. of people who do not complain of any throat trouble. (7) Diphtheria carriers.

### *Indications Associated with the Presence of Disease in Other Parts of the Body.*

In cases of disease of other parts of the body the tonsil may be the focus of infection. Here the indications for enucleation are more difficult to state. The patient's age and general health must be taken into account. Other sources of septic infection should be sought for and removed—e.g., in the teeth, paranasal sinuses, genito-urinary and alimentary tracts. It is not desirable to remove apparently healthy tonsils merely because no other cause can be found for the patient's trouble. There should be definite evidence that the tonsils are themselves diseased. The "focus of infection" theory is rather overdone at present. One sees patients who have had all their teeth extracted, their appendices removed, their tonsils enucleated, and yet are no better, or even worse, for all this operative interference. The case is clear, however, if a history is obtained such as that, following an attack of tonsillitis, the patient has suffered from rheumatism.

### *Contra-indications to Operation.*

Contra-indications to operation are as follows. Fever: The temperature should always be taken on admission and again before operation, as the child may be developing an infectious disease. *Hæmophilia*: The surgeon should inquire as to any history of bleeding, and, if necessary, test the clotting time of the blood. Acidosis: The urine should be tested. This can only be done if patients are admitted to hospital on the day before operation. Advanced rheumatoid arthritis, pulmonary tuberculosis, diabetes (serious cases), and arterio-sclerosis.

### *Methods of Choice in Children and Adults.*

There does not appear to be any useful "halfway house" between gargles such as peroxide of hydrogen (two teaspoonfuls of a 3 per cent. solution in a large wineglassful of cold water) or phenol sodique on the one hand, and enucleation of the tonsils on the other. Slitting up or cauterising the tonsil crypts, separation of the plica triangularis (circumcision of the tonsil), and the application of caustic pastes have not found much favour. Reports on the results of X ray treatment are decidedly adverse. Before operating, the patient's mouth should be rendered as aseptic as possible; in adults especially the teeth should be attended to before the tonsil operation. All specialists have felt the difficulty of determining in many cases whether the condition of the tonsils was such as to call for enucleation. Indiscriminate enucleation has brought the operation into some disrepute. An opinion should not be given during or immediately after an attack of coryza. Conservative treatment—e.g., nose washes, inhalations, and gargles—should be prescribed and the child seen again later. There are seldom any indications for enucleation before the age of 3 or 4 years, though adenoids may have to be removed in infants. (Tonsils should not be enucleated merely because adenoids are being removed. If the tonsils become greatly enlarged and give trouble after the adenoid operation they can be dealt with later.)

The old operation of tonsillotomy, or, more correctly, partial tonsillectomy, has been abandoned by almost all specialists in Anglo-Saxon countries because it was so often followed by recurrence of tonsillitis and even peritonsillar abscess. The question, therefore, of the choice of operation resolves itself into a dispute as to the respective merits of the guillotine and the dissection methods. Some hold that practically all tonsils can be enucleated with the guillotine, while others believe that dissection is the only correct procedure. Most surgeons, however, find that each method is suited for certain cases—i.e., that in practically all children, certainly in those who have not been previously operated upon, the tonsils can be entirely enucleated with a suitable guillotine. In only a few cases, where the tonsils are adherent to the surrounding structures, do they require to be dealt with by the dissection method under a general anæsthetic. It is true that in a very small proportion of cases the enucleation is not quite complete—a piece of the upper or lower pole being left; this error can, as a rule, be rectified with the guillotine if it is discovered before the child comes out of the anæsthetic. In adults, on the other hand, the dissection method, with the aid of local anæsthesia, is to be preferred. Such cases have very often had one or more attacks of peritonsillar abscess which have given rise to adhesions and render the operation difficult.

It is a mistake to say that only *specialists* should enucleate tonsils. The truth is that *only those who can should do the operation*. A man or woman with sufficient manual dexterity, who has held the post of house surgeon or clinical assistant for six months in an ear and throat department, is quite competent to perform the Whillis-Sluder operation or to enucleate by the dissection method.

J. S. Fraser, M.B., F.R.C.S. Edin.,
Surgeon to the Ear, Nose and Throat Department, Royal Infirmary, Edinburgh; Lecturer on Diseases of the Larynx, Ear and Nose, Edinburgh University.

# Special Articles.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Action against a Medical Man.*

AN action was heard in Dublin last week before Mr. Justice Hanna, in which Miss R. de Cadiz sued Dr. T. G. Moorhead, Regius professor of physic in Dublin University, for damages for assault. She alleged that on Oct. 3rd, 1924, when she was a patient in Monkstown Hospital suffering from severe spinal injury and fracture, the defendant, without her authority or consent, entered the private ward in which she was, and, despite her protests, assaulted her, whereby she was seriously injured in her health. For loss due to inability to attend business she claimed £1000. From the evidence it appeared that Dr. Moorhead, in his capacity of consulting physician to Monkstown Hospital, was invited by Dr. R. de C. Wheeler, one of the medical officers to the hospital, in whose care the plaintiff was, to see her in consultation. He made a physical examination in the presence of Dr. Wheeler and of the matron. The plaintiff declared that the examination was made roughly and without proper consideration. This was denied, not only by Dr. Moorhead, but by Dr. Wheeler and the matron. They stated, moreover, that the lady coöperated with Dr. Moorhead throughout the examination, and that the examination was the routine examination that any physician would make in a case of the kind. Evidence was given by several medical men that the patient had no signs of physical injury to the spine either before or since her examination by Dr. Moorhead, and that in reality she suffered from hysteria. After two days' hearing the jury returned a verdict that "there was no assault," and judgment was given for the defendant with costs. In his charge to the jury, Mr. Justice Hanna stated the law as regards the rights of patients and medical men in an examination. The legal basis, said his lordship, was the consent of the patient. When a patient brought in a doctor there was either an implied or an expressed consent that the doctor should be entitled to do all such acts as he considered reasonably necessary in his opinion, having regard to the state of medical knowledge and his own experience, to discharge his duty in making a diagnosis. But it was always subject to this—that, if he proposed to do any act dangerous or risky or painful to the patient, he should give the patient such information as would enable the patient to give or withhold consent.

The case has drawn attention once again to the great danger to which medical men are exposed in the course of their professional work. In this instance, as the reward of a charitable action, Dr. Moorhead has had to defend himself in the courts for two strenuous days, and has, although the verdict is in his favour, been put, no doubt, to considerable expense. He has the sympathy of all in the annoyance from which he has suffered.

### *The Medical Register Bill.*

The Medical Register Bill (1926) has passed both Houses of the Oireachtas. It carries on the present arrangements for medical registration for six months, or, at the discretion of the Executive Council, for twelve. It is stated that the uncertainty of the situation has had a marked effect upon the number of fresh students entering the medical school in Trinity College, Dublin, this term. The average number entering annually during the ten years before the war was 66. After demobilisation this rose abnormally to an average of 110. When the effect of the after-war conditions passed off, the numbers fell temporarily below the average, as was natural, but in 1924 they rose again to 61, and would probably have been still higher but for the rumours even then current as to the Irish Free State Government's intentions. This year the number has fallen to 35, the lowest since 1892. Further, of the 61 who entered in 1924, six have left to enter other medical schools outside the Free State, and a few students from other years have done the same.

### *County Galway Board of Health.*

Some time ago the County Galway Board of Health, finding itself in financial difficulties, invited all its employees, including its medical officers, to consent to a deduction of 10 per cent. in their salaries. None of the medical officers agreed to the request, and as a matter of fact, only one employee—a dispensary caretaker—agreed to the deduction. The salaries for the last quarter were paid less 10 per cent., and were received as payments "on account." The Board has now been notified by the Department of Local Government and Public Health that the deduction was illegal, and arrangements are being made to obtain an overdraft, so that the Board may meet its liabilities.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Conjunctivitis in Public Baths.*

CONJUNCTIVITIS has been frequent in recent years among people bathing in certain municipal swimming baths. The infection is slight in character, and under proper care clears up within a few weeks. Dr. Comberg, of the University Clinic for the Diseases of the Eye, has stated that among 250 swimmers examined by him he discovered ten who were not even aware that they were suffering from an eye disease, and it is evident that ignorance of this kind helps to spread the disease. The epidemic began in 1921, and 416 cases have been recognised; but during the last year energetic measures have been taken in the swimming baths and the disease has entirely disappeared. Dr. Seligmann, head of the laboratory of the City of Berlin, has remarked that sometimes the disease is conveyed by the linen, but more frequently by the water. The virus is unknown, but the municipal authorities have been successful in destroying it, although certain municipal baths are visited sometimes by 1500 persons a day, and overcrowding is very favourable to infection. This success is a result of adding disinfectants to the water, and the continuous influx of chlorine gas has proved particularly efficacious. Chemical and bacteriological examinations of the water were made every three days, and in testing some water which had not been changed for five months it was found that no germs were present. Eradication of conjunctivitis was not the only advantage of the disinfection, for, of course, there is a considerable saving of money if fresh water need not be supplied so frequently, and the price of the individual bath can be considerably reduced.

### *Medical Publications in Germany.*

According to a report of the Medical Publishers' Union there has been a considerable decrease in the number of medical publications of recent years. Apart from periodicals the number of publications in 1908 was 1334; it decreased to 1109 in 1923, and as a result of inflation fell to 827 in 1924. Old books are more frequently reprinted than new ones, because the financial risk of the publishers is less if the books have already gained their reputations. Research work is still flourishing in Germany, but publishers, owing to the general financial position, are unable to risk money on new books unless they can be sure of a demand from the medical public. It is a frequent complaint that German medical books have become extremely expensive, and that their sale has therefore fallen off; but this idea is incorrect. In 1908 the average price of books was M.6·07; in 1925 it was M.9·04. This increase of only 49 per cent. corresponds to the general rise in the price of necessaries. Bigger sales would, of course, permit of cheaper production.

### *Results of Cæsarean Section.*

Before the Berlin Gynæcological Society Dr. Wille reported that in the obstetric department of the Charité Hospital during the last 15 years there have been 357 Cæsarean sections among 28,917 births—that is, 1·2 per cent. of the whole number. The mortality from the operation itself was only 1·4 per cent. 119 of the patients became pregnant again; a second Cæsarean section was necessary in 49 cases; a third in 19 cases; and a fourth in one case. In 13 of the 119 cases in which pregnancy followed the operation there was spontaneous delivery, the duration of labour being on an average 21 hours. In 18 instances other operations became necessary. There were four cases of rupture of the sutured uterus, in three of which the patient was saved by sewing up the wall again. The ruptures were due either to defective suture or to the fact that healing by first intention was not obtained because of the patient's feverish condition.

### *Post-graduate Lectures by Broadcasting.*

Post-graduate lectures by broadcasting are now delivered on the second and fourth Fridays of the month from 8 to 8.45 P.M., as from Feb. 12th. After an introductory address by Prof. K. Adam, honorary secretary to the Institute for Post-graduate Study, the first lecture was delivered by Prof. W. Körte, the present chairman of the German Surgical Association, on Intestinal Obstruction: its Diagnosis and Treatment.

## UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

### *Annual Report of the Surgeon-General.*

THE Secretary of the Treasury has transmitted to Congress the annual report of the Surgeon-General of the U.S. Public Health Service for the fiscal year ending June 30th, 1925. The most notable event recorded in the international field is the signing of the pan-American Sanitary Code by 18 of the American Republics. The pact provides for the collection and distribution of information on the prevalence of communicable diseases and standardises the measures to be taken to prevent their transmission from one country to another. The pan American Sanitary Bureau will no doubt work in close association with the Health Section of the League of Nations. Both human and rodent plague were detected on board incoming vessels by the quarantine service, but no case of plague was imported. For almost the first time in the history of the service no ship was detained on account of yellow fever. Cases were reported from El Salvador, Central America, from three countries in South America, and from the Gold Coast and Nigeria in Africa. The total world incidence, however, is the lowest yet recorded. At Los Angeles, California, there was an outbreak of pneumonic plague with 31 deaths and 8 cases of the bubonic type with 3 deaths. This epidemic and two epidemics of rodent plague in other parts of the country were controlled by the public health service.

The report states that the firework celebrations on July 4th were responsible for 111 killed and 1030 injured, including 148 blinded in one or both eyes.

### *Epidemic of Poliomyelitis apparently Milk borne.*

From the City of Cortland, New York, comes the report of an epidemic of poliomyelitis that has been traced to a dairy boy. The facts are of sufficient importance to be given in some detail. On Dec. 7th a boy of 16 who worked on a dairy farm became sick with fever, headache, pain in the back, and some diarrhœa. In spite of progressive weakness in his hands he continued to work until Dec. 11th. On that day he was definitely paralysed in his entire left arm and right deltoid but succeeded in milking three cows with his right hand. He was seen by a physician on this day who recorded his temperature as 101° F. In addition to milking cows the boy carried milk to the cooler and assisted in filling cans from the cooler, and thus came in contact with practically all the milk produced in the dairy. The City of Cortland has a population of about 15,000 and uses approximately 5700 quarts of milk a day. The dairy above referred to supplies 215 quarts of unpasteurised milk to a dealer in Cortland whose total daily output is 240 quarts. The onset of subsequent cases in Cortland was as follows: Dec. 14th, 1; Dec. 10th, 2; Dec. 18th, 2; Dec. 19th, 1. All of these cases had drunk the suspected milk. It was supplied regularly to the families of four cases; one had drunk it three times daily in a restaurant, and the sixth consumed some of the milk at a gathering that he attended six days before the onset of his illness. Three more cases developed on Dec. 25th; one only had not taken any of the milk, and this one is considered a doubtful case.

### *Housing and Disease.*

Interesting figures bearing on the influence of housing on health have been published by Dr. W. H. Guilfoy, of the New York City Health Department. Infantile mortality varies greatly with conditions. In two crowded negro districts it was between 100 and 120 per 1000 births; in congested east side Italian districts it ranged from 85 to 90; whilst in the Washington Heights area, whose inhabitants are white and reasonably well off (incomes under $2500 yearly), the rate was 48. In this part of the city there are hundreds of new garden apartments, which are well ventilated and well lighted. It is an interesting fact, however, that in two typical Jewish districts, in which overcrowding was as marked as elsewhere, the mortality rate varied from 48 to 52 per cent.—that is, it was actually as satisfactory as that of Washington Heights. The fact that the Jews are eagerly availing themselves of the advantages of public health clinics can hardly explain so unusual a record, and so far as housekeeping is concerned the Jews are no better or worse than their neighbours. Possibly they have acquired a certain degree of immunity after generations of life under such conditions. The average infantile mortality for New York City as a whole was 65 per 1000 in 1925; 72 is considered a fairly good record in the United States, and the rate for New York has halved itself in 20 years. The figures for tuberculosis, needless to say, vary immensely with the conditions of life. In the lower end of New York City proper—that is, of Manhattan Island—the disease is rife. This part includes what is known as the lodging-house district, the Bowery district, and the Armenian and Greek sections, and one of these districts has a death-rate of 11·1 per 1000. The negro quarters are heavily infected, as also are the old tenement dwellings on the west side of the city as far as Fifty-fifth Street, which are chiefly inhabited by Irish, Scotch, English, and Germans. A typical Italian tenement house district has a death-rate from the disease of 1·4 per 1000; a typical negro district with a sprinkling of white people has a rate of 1·8; whilst in one part of the Harlem district the rate reaches 3·1. In the Riverside Drive district, however, the mortality does not reach 0·5 per 1000, and it is even less on Fifth Avenue. These are two of the most fashionable quarters of New York; but the extraordinary thing is that the Jews, in housing conditions as bad as those in which the death-rate is highest, have managed to keep their mortality down to the Riverside Drive figure. The same phenomenon is true of pneumonia. This disease generally takes its heaviest toll where the housing conditions are defective, and especially in those houses in which the heating is unsatisfactory and ventilation poor; a typical Italian district had 2·4 deaths per 1000. Yet the Jews in the crowded east side kept their death-rate from pneumonia far lower than the very rich in Fifth Avenue. Typical Jewish sections had a death-rate from pneumonia of from 0·08 to 0·25 per 1000, compared with 1·3 on Fifth Avenue. It is satisfactory to note that there is no instance of a high death-rate from the more important diseases in districts such as Washington Heights, where all the people live in modern houses, with effective ventilation an sunny rooms.

# Public Health Services.

## PUBLIC HEALTH IN LOCAL LEGISLATION.

A PRECEDENT means a good deal to those who promote legislation in the form of Local Bills. What Parliament has granted to one locality Parliament will probably not withhold from another. Two or three useful public health precedents are to be found in the Local Acts of 1925. Thus the progressive city of Bradford obtained a power of removing infirm and diseased persons to suitable institutions which, if it were not justified on grounds of health, would seem a grave interference with personal liberty. The power is given by Section 56 of the Bradford Corporation Act of last year. If the medical officer is satisfied that a series of carefully prescribed circumstances exists, he may apply to the magistrates for a removal and detention order. The first of these circumstances is that there is a person who is either (*a*) aged or infirm, or physically incapacitated, or living in insanitary premises, or under insanitary conditions; or else (*b*) suffering from grave chronic disease. The second is that in either case such person should be unable to look after himself properly, or to receive proper attention from those with whom he resides. The third condition is that "thorough inquiry and consideration" should show the necessity of his removal from the premises "in the public interest or in the interests of the health of such person or any person with whom he resides." When the medical officer has certified in writing that the case complies with all three of these conditions, he can go to a court of summary jurisdiction for an order, but there are still further safeguards to the liberty of the subject. All the allegations have to be substantiated before the magistrates by oral proof, and the bench can, if it thinks fit, direct a medical examination by a nominated doctor. The bench can then make an order for removal to a suitable hospital, infirmary, Poor-law or other institution, or other suitable place within or near the city, and for detention for three months. This period can be further extended or the order can be rescinded on application in a proper case. The new power would not authorise the detention of a healthy germ-carrier, but it is perhaps on these lines that Parliament may some day solve that problem too. Under another part of the Bradford Act (Section 68) trial will be given for five years to another innovation in our public health laws. The Infectious Disease (Notification) Act of 1889 is applied to venereal disease in the case of infants under 2 years of age, or in the case of adults who, after being informed by the doctor attending them or by the medical officer that further treatment is necessary in order to effect a cure, refuse or neglect to undergo such further treatment. There is a proviso that no one is to have the right or duty of such notification except a medical practitioner. Amongst other novel clauses in the Local Acts of 1925 is one (Section 104 of the Wolverhampton Corporation Act) which enlarges a medical officer's powers of tracing and preventing milk-borne disease. Where, under a previous Local Act, the medical officer or other authorised person takes a milk sample when inspecting cows, the owner of the cow must give immediate notice in writing to the local authority of the district in which the dairy is situated of any sale, disposal, or removal of the cow during the next six weeks.

These important precedents, which will doubtless be followed elsewhere, are mentioned in the recent report of the Select Committee on Local Legislation. For many years past the Committee has been recommending that a new Public Health Act should be passed which would make generally applicable a number of powers for which hitherto each local authority has had to ask individually and at the expense of promoting a Local Bill. This recommendation of the Committee at last received effect in the year now past. The Public Health Act of 1925 was the result; as, however, it did not receive the Royal Assent until the end of the summer session, it was not passed in time to save the labour and expense of a number of local authorities who were asking separately for the powers which the Act gives generally. The effect of the Act will be visible in the Local Acts of the current year. It will no longer be necessary to insert certain old familiar clauses as to contact with the dead bodies of infectious patients, medical examination of inmates of common lodging-houses, isolation, removal of tuberculosis cases to hospital, or the use of ambulances. It will not be necessary to authorise subscriptions to hospitals, provision of accommodation for hospital officers, lectures on health, or measures for the prevention of blindness. It will not be necessary to go again to Parliament for leave to forbid rag and bone dealers to sell food or toys, or to ask further powers to prevent the contamination of food intended for sale. Other clauses in the adoptive parts of last year's Public Health Act will not need to be demanded by Local Act—powers, for instance, for cleansing verminous articles, premises, or persons, or for dealing with offensive trades, or the nuisance which may arise from the occupation of tents, vans, sheds, and similar structures. The pity is that the Public Health Act of 1925 did not go further. It has converted into general law many important provisions previously of only local operation. But anyone who scans the public health provisions which it is still necessary to include specifically in the Bills which local authorities are presenting to Parliament for sanction in 1926 will see how much yet remains to be done before the country concedes as of general right all the powers which every well-administered locality requires and should possess.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 30TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox 300 (last week 365); scarlet fever, 1001; diphtheria, 1205; enteric fever, 44; pneumonia, 1302; puerperal fever, 60; cerebro-spinal fever, 11; acute poliomyelitis, 7; acute polio-encephalitis, 1; encephalitis lethargica, 61; dysentery, 4; ophthalmia neonatorum, 95. There were no cases of cholera, plague, or typhus notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there were 2 (1) deaths from enteric fever; none from small-pox; 76 (30) from measles; 8 (4) from scarlet fever; 58 (5) from whooping-cough; 15 (15) from diphtheria; 42 (9) from diarrhœa and enteritis under 2 years of age; and 78 (10) from influenza. The figures in parentheses are those for London itself.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

THE following appointments have been notified: Surg.-Comdrs. H. M. Braithwaite to the *Vivid*, addl., for R.N. Hospl., Plymouth, and as specialist in diseases of ear, nose, and throat; S. W. Grimwade to the *President*, addl., for 21 days' course at R.A.F. Medical Officers' School of Instruction; G. D. G. Fergusson to the *President*, addl., for three months' post-graduate course; and J. H. Burdett to the *Vivid*, addl., for R.N. Hospl., Plymouth, and as specialist in bacteriology. Surg. Lt.-Comdr. A. Craig to the *President*, addl., for three months' post-graduate course.

## ROYAL ARMY MEDICAL CORPS.

Maj. W. A. Spong to be Deputy Assistant Director-General at the War Office, vice Maj. and Bt. Lt.-Col. O. W. McSheehy (vacated).

Col. H. G. Martin, late R.A.M.C., retires on ret. pay.

Maj. and Bt. Lt.-Col. G. W. G. Hughes to be Lt.-Col., vice Lt.-Col. and Bt. Col. A. Chopping (promoted).

Maj. F. A. Robinson retires, receiving a gratuity, and Maj. W. R. Galwey retires on retd. pay.

Capt. (temp. Maj.) R. P. Cormack retires, receiving a gratuity, and relinquishes the temp. rank of Maj.

Lt. O. A. Owen-Flood, R.A.R. of O., to be temp. Lt.

### ARMY RESERVE OF OFFICERS.

Maj. J. A. G. Burton, late temp. Capt., R.A.M.C., to be Capt., and relinquishes the rank of Maj.

### MILITIA.

Capts. A. Picken and J. W. P. Harkness to be Majs.

### TERRITORIAL ARMY.

Maj. H. E. S. Richards, having attained the age limit, is retd., and retains his rank with permission to wear the prescribed uniform.

Capt. (Bt. Maj.) J. B. Orr from Supernumerary List, for service with the O.T.C., to be Capt. (Bt. Maj.).

Capt. A. F. L. Shields to be Maj.

Capt. A. R. Laurie (late R.A.M.C., S.R.) to be Capt.

R. N. Craig (late R.A.M.C.) to be Lt.

Supernumerary for Service with O.T.C.—Capt. (Bt. Maj.) J. B. Orr resigns command of the Infantry Unit, Aberdeen University Contgt., O.T.C.

## INDIAN MEDICAL SERVICES.

The King has approved the retirement of Lt.-Col. C. M. Mathew.

The services of Major F. A. Barker have been placed temporarily with the Government of Central Provinces, as officiating Inspector-General of Prisons. Capt. B. H. Singh, officiating civil surgeon, Midnapore, to act as Resident Medical Officer, Medical College Hospitals, Calcutta, vice Major N. C. Kapur, granted leave. Lieut.-Col. C. A. Sprawson, professor of medicine, King George's Medical College, Lucknow, to be a member of the United Provinces Medical Examinations, vice Maj. G. T. Burke, resigned.

# Obituary.

## HUGH RIDLEY PRENTICE, M.B., B.S. LOND., M.R.C.P. LOND.

WE have to record with deep regret the death of Dr. H. R. Prentice on Feb. 3rd at the Seamen's Hospital, Greenwich, at the age of 40.

After spending a period of his school days in Weimar, Prentice went to St. Bartholomew's Hospital for his medical education. After qualification, he was appointed senior resident to the Metropolitan Hospital, and later became resident medical officer to the National Hospital, Queen-square, where he worked for four years. Sir Victor Horsley, for whom he had great admiration, was one of his teachers. Later he was admitted to the membership of the Royal College of Physicians, and was appointed physician to the Belgrave Hospital for Children, physician to the West End Hospital for Nervous Diseases, and assistant physician to the Seamen's Hospital, Greenwich, where his demonstrations and lectures on neurology were highly esteemed by the post-graduate students of the London School of Clinical Medicine. During the years of war Dr. Prentice became an hon. lieutenant in the Royal Naval Medical Service, and was seconded to the Seamen's Hospital as chief administrative medical officer. In this way he continued to keep watch and ward over members of the Mercantile Marine during the stress which they underwent. So devotedly had he spent himself in the service of the sailor, that shortly after the war the board of management of the Seamen's Hospital Society appointed him medical superintendent and retained him as a member of the hon. medical staff. His great administrative capacity was also recognised by his being called to act as dean of the London School of Clinical Medicine. Into all his heavy work he threw himself with great energy, but recurring attacks of acute polyarthritis of obscure ætiology compelled him to limit his activities. Notwithstanding the severity of his illness and the progressive undermining of his constitution, he faced the future with indomitable courage, and continued to carry out his duties whenever opportunity offered. "No one who had the good fortune of being associated with him," writes a colleague, "could fail to recognise that he was a man of outstanding merit and worth. He had inherited great gifts. His father, who died when Prentice was 15 years of age, was an authority on music. To his devoted mother he owed much of his intellectual force and literary knowledge. He was an exceptionally well-read man, and was thoroughly en rapport with German and French literature. He had a profound knowledge of music, and was an expert violinist. He had a remarkably well-balanced, clear-thinking mind, and was a master of lucid exposition. His knowledge of medicine, and more particularly of neurology, was deep; and there can be no doubt that his illness robbed us of one who gave every promise of a great future as a clinician." Dr. Prentice was particularly fortunate in his married life. He leaves a widow and three boys, and it is hoped that his sons will carry on their father's high tradition of service.

## WILLIAM EVANS HOYLE, D.Sc. OXF., M.R.C.S. ENG.

Dr. W. E. Hoyle, who died at Porthcawl on Feb. 7th, was born at Manchester 70 years ago. As a student at Owens College, Manchester, he had a distinguished career, and in 1874 obtained a junior studentship at Christ Church, Oxford, where he graduated in the Natural Science School in 1877 with first-class honours. Thence he went to St. Bartholomew's Hospital, London, and three years later qualified M.R.C.S. and L.S.A. Not long afterwards he was appointed demonstrator of anatomy at Owens College, where he remained until nominated by the Government as naturalist under Sir John Murray in Edinburgh on the "Challenger" Expedition Commission. This position he held for six years; his special work was to report on the cephalopoda, and his report on them appeared in 1886. In 1889 he was given the post of keeper of the Manchester Museum and ten years later was chosen as the first director of the National Museum of Wales at Cardiff. This post he occupied for 25 years, until in 1924 ill-health compelled his retirement. To his work at Cardiff Dr. Hoyle brought the experience gained at Manchester and an intimate acquaintance with all aspects of museum routine obtained by visiting the chief museums on the continent and in the United States. He was president of the Zoological Section of the British Association at the Leicester meeting in 1907 and was also at one time president of the Museums Association. Besides his work in marine organisms, he translated Leuckhart's "Parasites of Man," and in addition to his great services as director of the National Museum at Cardiff, he took an active part in all Welsh national movements, acquiring a good knowledge of the Welsh language. Dr. Hoyle was twice married and leaves a widow and two daughters.

## EDWARD MOLYNEUX, M.B., CH.B. MANCH.

GREAT regret has been caused in Southport by the sudden death, on Feb. 11th at his residence at Little Weston, Cheshire, of Dr. E. Molyneux, in his sixty-first year. Not long ago Dr. Molyneux had been compelled by heart trouble to relinquish his practice in Southport, but had continued to give much time and attention to the work of the corporation, on which he served as a councillor and as vice-chairman of the health committee. The son of the late Mr. Joseph Molyneux, of Walton, he received his early education at Liverpool College, and his medical training at the University of Liverpool, graduating there as M.B., Ch.B. in 1890, and becoming M.R.C.S. and L.R.C.P. in the same year. As a student he gained honours in surgery, histology, physiology, and later he acted as demonstrator in physiology in the medical school. After qualification he held a series of resident appointments at the Royal Infirmary, Liverpool, which gave him wide experience, and this was later increased by his work as visiting physician to the Liverpool Fever Hospital and medical officer under the education committee. In 1892 he took up private practice in Cressington and remained there for nearly 16 years. Then he moved to Southport, where for 18 years more he was in busy practice. He found time, however, to take an active part in municipal affairs and also to keep up his keen interest in Association football; not infrequently it fell to his lot to render aid to injured players. Two of his sons served throughout the war. Both in professional and other circles, the loss of Dr. Molyneux will be greatly felt.

# Correspondence.

"Audi alteram partem."

## THE MEDICAL PROFESSION AND OSTEOPATHY.

*To the Editor of* The Lancet.

Sir,—It is clear that a determined attack is about to be launched by various sects of "unqualified" individuals, including osteopaths, chiropractors, bone-setters, and the like, to ensure State recognition. This attack is well organised and is engineered by many able men who have a strong following in Parliament and who have behind them the powerful and almost unanimous voice of the lay press. As a profession we have incurred the unpopularity of the press because we dislike medical "stunts" and vulgar publicity. The preliminary bombardment has already begun. Let us not confuse osteopathy with manipulative surgery. The latter has "won its spurs," is almost universally recognised, and is practised by many medical men, although formerly left largely to bone-setters, some of whom, such as Sir Herbert Barker, possessed very great ability. These bone-setters never claimed that they could cure every disease under the sun. They kept to their own field wherein, in spite of occasional disasters, they often did good and useful work.

Now the osteopaths make much more extravagant claims, and many of them claim that nearly all disease can be traced to minor displacements of the vertebræ. One can at any rate respect a good bone-setter because he is working upon rational lines, but what are we to think of an individual who claims to cure typhoid fever or tuberculosis, diphtheria or cancer, by manipulating the spine? Such theories are not only untenable, but constitute a grave public danger.

What is our duty as a profession towards this menace? In the first place, we obviously cannot afford to ignore the matter as beneath our notice, but must launch a powerful counter-attack. We must endeavour to educate the public and tell them the truth about osteopathy and manipulative work generally. We shall only weaken our position if we attempt to discredit the undoubted successes that osteopaths and bone-setters sometimes achieve when other methods have failed. Nothing has so harmed our reputation in the past as this refusal to face facts. We must meet these attacks with reasoned argument and a willingness to give credit where credit is due. How are our arguments to be brought to public notice? Much can be done in Parliament provided that our spokesmen marshal their arguments carefully and avoid giving the impression that they are swayed by mere prejudice.

Secondly, we must organise our own press campaign. Statements in the press by individuals are better avoided, but if some such body as the British Medical Association or the British Orthopædic Association would form a committee and draw up an authoritative and dispassionate pronouncement for the press upon the merits and dangers of osteopathy, only good could result. There is one particularly cruel and callous falsehood that the press never tire of asserting—namely, that bone-setters and other unqualified persons possess some special knowledge and skill which is not possessed by legitimate qualified specialists in this field. This calumny must be definitely and finally refuted. Mr. Elmslie most appropriately in a recent discussion pointed out the unfair advantage that bone-setters possess by the publicity that the press allows to their successful results and by the veil that it discreetly draws over their failures. Not long ago perhaps the most famous living bone-setter paid me the great compliment of permitting me to perform a manipulative operation upon his back. I could not help thinking that if this operation had been performed by another bone-setter, the press would have returned with great gusto to the congenial task of decrying professional neglect of bone-setting and of exalting unqualified practice.

Before the osteopaths can hope for State recognition they must bring forward evidence for their theories that will stand thorough scientific investigation. The evidence so far adduced is from a scientific view-point almost worthless. If there be aught of value in osteopathy, it is obvious that it can be most safely practised by persons with a thorough training in and qualification to practise medicine and surgery. It is earnestly to be hoped for the public good that, in this country at any rate, any diplomas or degrees that may be conferred by Colleges of Osteopathy will never be allowed to take the place of those qualifications permitting medical practice sanctioned by the General Council of Medical Education.

I am, Sir, yours faithfully,

A. G. Timbrell Fisher, *M.C.*, F.R.C.S. Eng.

Montagu-square, W., Feb. 15th, 1926.

## THE TREATMENT OF CANCER WITH LEAD.

*To the Editor of* The Lancet.

Sir,—During my recent trip to Europe I had the opportunity of seeing in great detail the work of the Liverpool Cancer Research Committee, especially that aspect of the researches conducted by Prof. W. Blair Bell. Through his kindness and that of the Vice-Chancellor of the University, Prof. J. G. Adami, I not only learned the general principles of the treatment of patients but also became acquainted with the organisation and methods of the interesting research group which has been formed in Liverpool for the study of various aspects of the cancer problem. Some of the facts have already appeared in print but others are not so well known, and I would like to set out the points which seem to me to mark a very important advance in the method of attacking a special problem and one which well might be employed more frequently in similar investigations concerning cancer and other diseases.

In the first place, the funds for the various studies, both chemical and pathological, were, and still are, provided by a group of generous citizens of Liverpool. After the guarantee of sufficient income was obtained, advisory groups were formed, made up from the staff of the various scientific departments of the University and practitioners of eminence both in medicine and surgery. The problem set was to carry on the work already begun by Prof. Blair Bell on the treatment of cancer by intravenous injections of colloidal lead and to see how it could be made most useful. As the preparations first made were weak and unstable, one of the most important problems to be solved was to devise a method by which the concentration and stability of the therapeutic agent could be increased. This being evidently a physico-chemical question, a group under the direction of Prof. W. C. McC. Lewis were put at work and have conducted a large series of investigations resulting in a very considerable improvement along the lines indicated, though as yet the product is so unstable and difficult to prepare as not to warrant the publication of the procedure, for the current practice is not regarded as final and is quite beyond the manipulative skill of the medical practitioner. As yet the lead suspension keeps only for a few days. It is hoped, however, that ultimately a more permanent colloid may be obtained which can then be made available for use in skilled hands. While it is regrettable that all sufferers from hopelessly advanced cancer cannot have the immediate benefits of the treatment, it is obvious that a premature distribution and the inevitable disparagement of so dangerous an agent which would result from the effects of its misuse could only end in a lamentable loss of life among those whom the treatment is designed to help. For in addition to the dangers of an imperfect or inaccurately assayed product it has been found that bad results can scarcely be avoided unless a very elaborate and painstaking study of the patient's general condition is made, so that only those with a considerable clinical experience in observing patients under lead treatment are able to obtain satisfactory results. When, however, the use of colloidal lead is surrounded with all these precautions the results are highly satisfactory, as the recent paper in THE LANCET by Prof. Blair Bell amply demonstrated.

But another phase of the situation is of very great interest. Not only has the mobilisation of the intellectual forces of the Department of Physical Chemistry contributed greatly to the success of the enterprise, but other groups have found fertile problems for study in various aspects of the work. The result has been not only the production of matter of direct value for the chief problem in hand, but numerous intellectual by-products, so to speak, have been prepared during the course of the main investigation, and these may ultimately lead to improvement in our, at present, very unsatisfactory treatment of lead poisoning and probably aid the solution of other clinical problems. Thus, not only has the situation resulted in what I regard as a remarkable practical achievement in the main problem attacked, which is the treatment of cancer, but the pure science departments of the University have been benefited by an intellectual fertilisation due directly to active interest in fresh and very human problems. We all need to be reminded occasionally that some of the abstruse studies made by the laboratory recluse and buried in technical journals behind a barricade of repellent mathematical formulæ may upon occasion contribute astoundingly to human health and happiness. Such an occurrence as this is a healthy reminder of the importance of the university to the community in which it exists, entirely apart from the benefit derived from direct teaching. From all other aspects I am convinced that both the Cancer Committee and the University of Liverpool should be well satisfied with the results already achieved as showing not only how successful well-coördinated research can be, but how fertile in practical achievement. The future course of the work has been well planned. It is hoped that with the treatment on a working basis the guarantors can gradually be relieved of their financial burden and the committee will be able to derive sufficient funds from the fees of patients taking the treatment to carry on the work. It has been the practice heretofore to turn all fees into the research fund and pay from that fund modest salaries to those who were giving largely or wholly of their time. It is hoped that further development may take place in this direction and eventually result in the accumulation of considerable endowment for permanent support of future investigation.

I am, Sir, yours faithfully,
FRANCIS CARTER WOOD,
Director of the Institute of Cancer Research,
Jan. 10th, 1926 Columbia University, New York.

## CHARING CROSS HOSPITAL INSTITUTE OF PATHOLOGY

*To the Editor of* THE LANCET.

SIR,—A short time ago I saw in a daily paper an article giving an account of the Charing Cross Hospital Pathological Scheme. From the examples given of the proposed fees the scheme is obviously a charitable one, but no mention was made of any desire to prevent abuse of the charity. I should like to know what means will be adopted to prevent this abuse. The value of the opinion of a pathologist who would consent to such fees, when working for himself, would not amount to much, but when backed by the name of a London hospital the public may be deceived into thinking that they are paying the market value of the best advice. They will notice that, whereas the value of the advice of a physician or surgeon is measured in guineas, that of the advice of the pathologist is measured in shillings. It is stated that the director is to sign all reports. I should like to ask him if he intends to carry out personally all the investigations on which the reports are based. If not he will be in the position of a practitioner who signs medical certificates without examining the patient and may also be liable to be accused of covering unqualified practice.

The whole scheme appears to me to be a disgrace to the hospital and to the University of London for allowing their laboratories to be used for the purpose of undercutting the fees for pathological work. It is quite time that the attention of the General Medical Council was drawn to this and similar schemes so as to determine the position of pathologists who consent to work such schemes. The conduct of such pathologists would appear to be as "infamous" as that of many practitioners who are brought before the Council. Unfortunately, there are many medical men in high positions who regard pathologists as an inferior order of being and who support these schemes for supplying cheap pathological opinions. They adopt a code of ethics when dealing with pathologists different to that which they adopt when dealing with their clinical colleagues. The whole scheme is another example of the contempt with which pathology and pathologists are regarded by our universities and medical schools and by the profession generally.

Dr Murray has suggested another scheme which the Charing Cross Hospital might usefully adopt, and I venture to suggest two more. Why does not the hospital bring forward a scheme for supplying medical and surgical advice through its honorary staff on terms and for fees similar to those suggested for pathological advice? Why, again, does it not undertake to dispense medicines at prices which would undercut those charges by pharmaceutical chemists?

I am, Sir, yours faithfully,
CHARLES POWELL WHITE.
Manchester, Feb 15th, 1926

*To the Editor of* THE LANCET.

SIR,—Dr Murray's suggestion that the Hospital for Epilepsy and Paralysis might speculate with a laundering business would not appeal to the hospital committee nor to me, as I have no experience in the management of such a business, except the weekly wave of anger and of sorrow I suffer The hospital, however, can claim to know something of pathological investigations, it is not competing with ordinary business, and for these reasons I disagree with Dr. Murray —I am, Sir, yours faithfully,

H. W. BURLEIGH,
Feb 12th, 1926 Secretary and General Superintendent.

## THYROID GLAND AND CALCIUM THERAPY.

*To the Editor of* THE LANCET.

SIR,—This interesting correspondence evokes old memories of how so many chilblains in pre-war days were certainly cured by calcium lactate. Small doses of thyroid were added only if its use was otherwise indicated. Dr Drake has probably supplied the correct explanation of the present discredit thrown upon this treatment when he says that only the failures now reach the specialist. I recall the days when my late husband, Dr. T. D. Savill, wrote on the efficacy of calcium chloride, in large doses, for many skin diseases; it should be remembered that where active toxæmia was in operation he found its action was not remarkable

As regards the other type of case described so clearly by Dr. Barber, girls and women with firm, swollen, blue ankles, I have seen many in hospital and in private practice and have been surprised by the remarkable fact that many of these cases do not have chilblains. Some feel quite well and only object to the thick ankles because of the present-day short skirts. The general obesity corresponded in all my cases to the pituitary deficiency type; some presented also some thyroid deficiency, but in lesser degree In most cases a loaded cæcum or sigmoid flexure was easily detected; in two there was a history of the condition having followed pneumonia, in two it followed rheumatic fever. Treatment is necessarily long, so the majority disappear after slight improvement occurs. I should like to report one who persevered until cured.

Miss C, aged 32, had double pneumonia six years previously, and since then had become stout, with scanty menses and swollen blue legs and ankles. She had large blue breasts, blue extensor upper arms, thick blue ankles, pads on lower chest, abdomen, and thighs; and was easily fatigued. The cæcum was palpable. A catheter specimen revealed *Staphylococcus aureus*. An autogenous vaccine was given, also pituitary extract, and a mild rhythmic sinusoidal current daily to both legs. Improvement at once was noticed. The constipation was treated, a vitamin-containing diet ordered; the pituitary extract by mouth and electricity with a faradic battery were continued at her home for nine months. I saw her frequently during the first three months; during the following six months she carried on alone. During these six months she also took 1/10 gr. parathyroid daily. When I saw her after nine months' treatment she was another woman—the periods were normal, she felt well, the ankles were slim, there were no pads or blueness on limbs or body.

All my other cases with swollen blue ankles began to improve with electricity, pituitary extract, and removal of toxæmia, but were not wise enough to persevere. I do not know if the parathyroid played any part in the cure of the above case, but of its value in varicose ulcers I am convinced. Calcium lactate and ultra-violet light is given as a routine to all my hospital cases; parathyroid is only ordered in obstinate cases. Many of the patients have remarked spontaneously that they dated their first big step forward from the week they began parathyroid.—I am, Sir, yours faithfully,

Devonshire-place, W., Feb. 15th, 1926. Agnes Savill.

*To the Editor of* The Lancet.

Sir,—I take up the cudgels on behalf of the treatment of chilblains by calcium lactate. At one time I had a large practice among school and college girls, a class largely addicted to chilblains. By the use of this drug prophylactically, those who were prone to bad chilblains remained free, and those who took it for the first time, when attacked by chilblains, found that these cleared up quickly. It is my impression that about 90 per cent. of chilblains can be cured by this method. But the calcium lactate must be taken under certain conditions.

1. On an empty stomach, preferably before breakfast immediately on rising. For prophylaxis, my prescription was three 5 gr. tablets daily on rising, before breakfast, for a week; for treatment, nine daily, three taken one hour before meals.
2. Not in excess. It is said that calcium in excess defeats its own object and I have found this to be so, though I do not understand the raison d'être. For this reason I never give more than 25 5 gr. tablets (one bottle) in six weeks.

In the class of case mentioned by Dr. Barber I must confess to failure. These girls have purple, cold, swollen hands even in summer. If pressure by the thumb be made on the dorsum of the hand to empty the capillary circulation, the return is very much slower than normal. There must be some congenital constitutional failure affecting the peripheral circulation. One finds all stages up to definite Raynaud's disease. I have tried intestinal disinfectants without success, but not iodine as Dr. Barber suggests, and have been reduced to local treatment with massage and electricity to tide them through the winter avoiding bad chilblains.

Whether or no there be calcium deficiency in chilblain patients, surely it is possible that calcium lactate may still act as the final factor in increasing the osmotic pressure of the blood and thus preventing the local effusion in response to a local chill. Also, in girls, after puberty, the calcium content of the blood must vary considerably during the month, having regard to the monthly excretion of calcium. Many patients find that chilblains are more apt to occur round about the menstrual period.

As regards parathyroid in this complaint, I have had very little experience, as I reserve the treatment for cases which do not clear up with calcium lactate only. I am, Sir, yours faithfully,

Walmer, Feb. 8th, 1926. D. C. Nasmyth.

## BROMO- AND IODO-PHENOLPHTHALEINS IN CHOLECYSTOGRAPHY.

*To the Editor of* The Lancet.

Sir,—As the use of these compounds is so new, I venture to draw attention to the results recently obtained in America with an average dose of 2·5 g. in 2 per cent. dilution in normal saline (*Jour. Amer. Med. Assoc.*, Jan. 23rd, 1926, p. 239). Doses of this strength are less likely to produce violent reactions than the quantities hitherto employed, and will probably give adequate shadows.

I am, Sir, yours faithfully,
W. H. Martindale.

New Cavendish-street, W., Feb. 12th, 1926.

## THE TWORT-D'HERELLE PHENOMENON.

*To the Editor of* The Lancet.

Sir,—In your issue of Jan. 23rd Dr. Gratia and Dr. Rhodes draw attention to their work on the breaking down of dead bacteria in the presence of living ones. In my last paper in The Lancet, in which I dealt with this question, I made no mention of their earlier work which was carried out along the same lines. At the time I was unaware of their investigations, and I much regret they were overlooked. The experimental results with saline emulsions obtained by Dr. Gratia and Dr. Rhodes and their conclusions differ from mine. In reply to their criticisms I may say that in carrying out my experiments I did not overlook the question of autolysis, and my view is that autolysis or "isophagy" is not sufficient to explain my results. These convince me that if the experiment is suitably arranged, the lysis of dead bacteria, in the presence of living ones of the same variety, only takes place quickly and to any appreciable extent when the transmissible lysin is also present. However, there is a *possibility* that the "transmissible lysin" never produces lysis directly, but acts by killing the bacteria in such a manner that the autolysins which they contain are enabled to produce lysis, or to assist in this process. There are several simple chemical methods of setting free the autloysins while the bacteria are being killed, and these lysins will partially clear a bacterial emulsion that has been killed by heat without the presence of the transmissible lysin. The manner, however, in which the transmissible lysin acts is a wider problem with which I will endeavour to deal more fully in a paper which I hope to publish shortly.

I am, Sir, yours faithfully,
F. W. Twort.

The Brown Institution, University of London,
Feb. 12th, 1926.

## TRANSFUSION OF WHOLE BLOOD.

*To the Editor of* The Lancet.

Sir,—The transfusion of whole blood is in many instances one of the most effective measures in the armamentarium of the medical practitioner. It would probably be much more widely practised in this country were it not for a widespread idea that it is both a difficult and dangerous operation. The difficulty of the operation by the citrate method is little greater, provided a suitable donor, than that of the infusion of saline, but both in this country and America warning voices, the latest of which to date is that of Dr. Robert Platt in your issue of Jan. 23rd, are continually being raised against the dangers of this method.

Both at St. Thomas's Hospital and the Wolverhampton and Staffordshire General Hospital I have, in the course of the last five years, been concerned as the selector of a suitable donor in a considerable number of blood transfusions. In every case citrate was used and in no case save one did anything other than benefit result; the one exception was the case of a debilitated patient who suffered from some cardiac distress during the operation as the result of the too rapid introduction of blood into an enfeebled circulatory system; even in this case nothing in the nature of what is usually known as a "reaction" occurred. As the result of my observations I have been forced to the conclusion that in all cases where "reactions" have occurred after the transfusion of blood by the citrate method they must have been due to faulty technique, which usually means the introduction of an incompatible blood. It is, perhaps, not sufficiently realised that the group agglutinins may and do occur in very different strengths in sera of the same group from different individuals[1]; the same applies to the agglutinable factors of the corpuscles. In THE LANCET of March 25th, 1922, I endeavoured to lay down the precautions which should be taken in performing a grouping test. Briefly, these consist in the use of a grouping serum of high titre, the dilution of the blood to be agglutinated and the microscopical observation of the test over a period of at least ten minutes. In the absence of these precautions it is easy to miss minor degrees of agglutination.

In this connexion it may be pointed out that one or other of the agglutinable factors may be present in certain corpuscles to such a small extent as entirely to escape observation except by absorption methods. This fact became apparent to me in the course of a series of such absorption tests performed by myself some years ago; this means that certain bloods apparently of Groups II. or III. are really of Group I. (Moss). This fact seems to be the explanation of certain anomalies described by Prof. E. E. Glynn at the Liverpool meeting of the Pathological Association in January, 1925, and also of the extensive observations of Guthrie and Huck, though these latter workers attributed their results to the presence of a further agglutinable factor.

Could it only be generally realised what a safe and simple procedure the transfusion of whole blood by the citrate method really is, it would probably find a much more widespread application in this country than it now has, and many cases must be occurring daily in which it is the only measure offering any real hope of the salvation of life.

I am, Sir, yours faithfully,
Wolverhampton, Feb. 14th, 1926. S. C. DYKE.

## A PROJECTED NURSING HOME.

*To the Editor of* THE LANCET.

SIR,—With respect to the leading article on "The Paying Patient" in your last issue, for some weeks I have been trying, at the suggestion of and in consultation with a number of West-end specialists, to establish a nursing home which will be free from many of the defects of existing homes, and will have advantages possessed by few, if any. A house is available offering the following:—

1. High open situation, with free access of air and light; little traffic, no 'buses or trams, and freedom from noise, dust, and smells; and within 15 minutes by car from the West End. Five minutes from a station.

2. Good bedrooms, with magnificent views over open country; a very fine lounge, dining-room, conservatories, and large garden available for convalescents and those not confined to their rooms. Accommodation for about 26 patients would be available to begin with, with ample room for extension.

3. In addition to an up-to-date operating theatre, there will be an X ray plant, apparatus for electrical treatment of all kinds, and a pathological laboratory.

The home would be under the management of a resident medical superintendent who would supervise all details in the interest of the patients, and not subordinate their comfort, &c., to rules and restrictions to secure ease of administration. Charges would not be exorbitant and below the average of existing West End homes.

So far, however, it has been found impossible to secure the necessary capital, amounting to £20,000 to £25,000; it is, of course, undesirable that any of it should be provided by those who would have their patients in the home. All details have been worked out and estimates prepared. A dividend at the rate of 10 to 15 per cent. could be earned, but if the money could be provided by someone who would be content with (say) 6 per cent., a proportionate reduction in fees could be made for the benefit of the patients who needed this. The scheme has been submitted to some very prominent members of the profession and has their approval.

In sending you this letter I fully realise you may find yourself unable to publish all or any of it; but possibly you may know of somebody who would like to investigate it with a view to helping the scheme forward. I am, Sir, yours faithfully,
E. C. PLUMMER.
St. Faith's Nursing Home, Mount Park-road, Ealing, W.
Feb 15th, 1926.

## METOL POISONING.

*To the Editor of* THE LANCET.

SIR,—In August, 1925, a young lady chemist, after a week's extra use of metol, noticed a rash between the fingers "with small, mattery heads," later spreading to the backs and palms of hands, face, and neck, some swelling and irritation, especially of fingers and eyelids. The rash became dry and scaly with cracks on fingers and chin. Various emollient ointments and lotions were tried, but it has recurred at intervals, especially on using metol or even dispensing it, although rubber gloves have been used with some success. I am told that the irritating cause is an impurity in the metol and is chemically akin to the dye used in cheap furs and producing a dermatitis. Perhaps readers of THE LANCET would indicate a line of treatment.—I am, Sir, yours faithfully,
Cowes, I.W., Feb. 12th, 1926. L. P. GIBSON.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee 57 cases were considered and £577 voted to 14 applicants. The following are notes on some of the cases relieved:—

Widow, aged 50, of M.R.C.S. (King's Coll.) who practised in Middlesex and died last year. When the late husband's estate is settled up income will be about £200 a year for herself and three children, 2 boys, 13 and 8 years, and girl of 11. Unable to meet the educational expenses of the children. The Committee made a small grant to render the case eligible for our Guild's assistance with education.

Widow, aged 37, of M.B. Manch. 1908 who practised in Wales and died last April. Left with three children aged 10, 5, and 2 without any income and too ill at present to do anything towards maintenance of self or children. Since husband's death they have been helped by relatives, but the applicant is asking for educational assistance. The Committee made a small grant so that our Guild can deal with the case.

Daughter, aged 70, of M.D. St. And. who practised in Lancashire and New Zealand, and died in 1872. She returned recently from Australia owing to her brother's death. Came home to stay with a married sister in the Midlands, but owing to ill health she removed further south and is now living in one room. Only income £32 per annum. Very favourable report received about this case. Voted £18 in 12 monthly instalments.

L.A.H. Dublin 1907, aged 47, married, one son aged 11. Six years war service. Sold practice before joining up. Has repeated attacks of malaria. Now unable to find employment. Medical work for the last 12 months brought in £105. Officers' Association granted £15. Has pawned and sold various articles. Voted £7.

Widow, aged 65, of M.R.C.S. Eng. (King's Coll.) who practised in London and died in 1923. Only income is the rent received from a house which brings in about £12 net per annum. Has £30 left from sale of furniture. Lives in one room at 9s. a week. £3 voted by the Committee and application has been made for a grant from the Masonic Benevolent Fund.

Daughter aged 70, of M.R.C.S. Eng. (St. Bart.'s) who practised in Worcestershire and died in 1872. Used to make a living by teaching small children, but had to give up this to look after her mother who died in 1920. Tries to let a portion of a house but is at present without a tenant. She received £35 from letting and a brother allowed her £27. She has had the O.A.P. since August last year. Rent and rates £38. Voted £9 in 12 monthly instalments.

Widow, aged 37, of L.R.C.P. Edin. 1917 who practised in Wales and died last March. In great trouble as the house and shop where she carries on a small business has been sold, and she will have to vacate the premises in a few months' time. Has one boy aged 12 for whom she asks educational assistance. The Committee handed it over to our Guild to deal with, together with a small grant.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

# CRIMINAL OFFENCES AND PROSTATIC ENLARGEMENT.

## A MEDICO-LEGAL DISCUSSION.

AT a meeting of the Medico-Legal Society, held at the rooms of the Medical Society of London on Feb. 16th, Dr. Nathan Raw, the President, occupying the chair, Dr. G. Halliday Sutherland read a paper on Enlargement of the Prostate in Relation to Criminal Offences. He began by giving a detailed description of the anatomy of the gland and the surrounding structures by means of the epidiascope, and showed some illustrations of histological specimens from the prostate of other animals by way of comparison. He indicated the particular direction in which only enlargement of the organ could take place in man—namely, between the neck of the bladder in front and the seminal vesicles behind, the enlargement pushing the bladder in front of it, and giving rise to micturition troubles. He also described the urethroscopic appearances in cases of chronic masturbation. Two-thirds of the prostate consisted of muscle, one-third of gland substance, and its average normal weight was 4½ drachms; it was supplied with motor, sensory, and trophic nerves. Sir Henry Thompson had shown, he said, that after 60 years of age the gland remained of the normal weight in 60 per cent., in 11·6 per cent. there was atrophy of it after that age, and it was enlarged after 60 in the remainder. Nearly half the men in whom the gland was enlarged after 60 had made no complaint in reference to it. The most frequent cause of the enlargement was the development of an adenoma; it was not a true hypertrophy; there was also dilatation present in most. Dr. Sutherland had satisfied himself that the dilatation was secondary to the constriction of the little ducts, the latter due to inflammatory reaction or as part of a general arterio-sclerotic change in the individual.

The earliest symptom noted by the patient was a gradually increasing frequency of micturition, calling first once in the night, later twice. In some cases there was a sudden retention of urine—namely, when the enlarged portion fell over the opening of the urethra, or by an adenomatous growth blocking that channel. In others there was a feeling of weight and discomfort in the perineum, with constipation. This last he attributed to the sensitiveness of the whole area, which led to a deferment as long as possible of the act of defæcation. There was also a dull aching in the back or a sacral pain, which sometimes radiated down the inside of the thighs. Particularly was pain felt on micturition and defæcation. Thirst and a dry skin were other concomitants. In later stages cystitis might develop, pass to the kidneys, lead to pyelonephritis, uræmia, and so to death.

Not much, said Dr. Sutherland, was to be found in literature dealing with the medico-legal aspects of prostatic enlargement, but it was generally agreed that a likely association of this enlargement was the commission of lewd acts, passing on to criminal ones, in persons previously above reproach. He quoted some examples, the persons concerned apparently deriving satisfaction from merely touching the parts or members of the opposite sex. Disease in the sexual area always had a profound effect on the mind, quite out of proportion to that caused by disease in any other part. In cases of the kind under discussion the stimulus might be so urgent that the reader of the paper thought they might well come under the second category of the McNaghten judgment. In most of the criminal cases he thought the wisest course was to get an undertaking from relatives to take care of the guilty person, thus performing a similar function to that carried out by the Procurator-Fiscal in Scotland.

Sir Bernard Spilsbury, who followed, said the principal type of enlarged prostate he had met with in his post-mortem experience was that in which all the elements of the gland were increased in bulk, not only the gland itself, but also the muscle and fibrous tissue which formed the support of the gland. In cases of enlarged prostate removed by operation, adenoma was rare comparatively. In considering the legal side of certain cases of sexual perversion, there was a liability to unduly stress the functions of this gland. In some cases removal of the gland had not cured the abnormal impulses of the individual. Sexual perversion he attributed rather to pressure effects on the sexual organs generally; sometimes there were definite obstructive effects. Moreover, after operation scar tissue formed, and the contraction of this might again be a source of irritation.

Dr. Graham Grant, speaking as a police surgeon, said he had been present at the trial of many persons brought up before the courts accused of committing indecent exposure, and declared that a large number of these offences occurred in public urinals. A common defence when men were stated to have remained there unduly long was that they were engaged in adjusting their truss, and he asked whether the pressure of a truss would cause sufficient sexual irritation to lead to offences of the kind under discussion.

Dr. M. I. Finucane spoke of the detailing of plain-clothes officers to watch out for cases referred to by the last speaker, and incidentally mentioned that in the West End particularly offences in lavatories were quite common. He elaborated the legal rights possessed by persons so charged to see a doctor, their own if they so desired.

Lord Riddell said he considered it a dangerous doctrine to give evidence of an enlarged prostate as a defence. Life consisted of a series of coats of varnish, and 60 seemed to be about the age when those varnish coats reached their zenith. They were either good or bad coats. Men who had hitherto led a good and wholesome life became at that age nice respectable old gentlemen; but those whose lives up to that stage could not be so described now suffered for their previous conduct; their minds became a kind of cesspool, and they gave evidence of that in their repulsive acts. Nothing had been mentioned in the discussion as to women. There was no prostate gland in women, yet self-exposure by women of various ages was not uncommon. Probably the rapid sequel in women showing this abnormality was to take them to an asylum. In all these matters it was necessary to proceed on broad lines, and if the various suggestions made as to special treatment of these perverts were carried out, society would soon get into a disorganised state. His own feeling was that men who committed the kind of offences under discussion should be severely punished. Usually they were exceedingly cunning and were quite aware of the crime they were committing, but were difficult to catch. He hoped that nothing which had been said in the discussion or in the paper would lead to these people being examined by police surgeons and in that way escaping their just treatment.

Further points made in the ensuing discussion were, that most of the elderly men accused of these acts showed some signs of senile dementia, and some of them when examined did not show an enlarged prostate. These acts, which were not committed by all possessors of an enlarged prostate, might be one of the earliest signs of a state which later might become certifiable. Another point made was that in these old men the acts in question represented the final flickerings of a sex passion which, nevertheless, was not equal to the performance of the normal sexual act. The urge was still there periodically, but the response was only partial, and the manifestations of it were accordingly bizarre. An aspect which was only once touched on was that of finding a consenting party of the opposite sex, and one speaker alluded to a case in which a middle-aged woman stated on her card that she showed special patience with old men.

Dr. Sutherland dealt in his reply with a number of the points raised in the discussion.

# Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary meeting of the Council of the College on Feb. 11th, Sir John Bland-Sutton, the President, in the chair, Sir D'Arcy Power was re-elected a representative of the College on the Council of Queen Victoria Jubilee Institute for Nurses.—The President reported that Prof. Sir Arthur Keith's remaining three Hunterian lectures, which had been postponed, would be given on Monday, Feb. 22nd, on the Taungs Anthropoid; its Zoological and Geological Position; Wednesday, Feb. 24th, on Fossil Anthropoids of Europe and of Asia; and on Friday, Feb. 26th, on the Kivu Gorilla and its Bearing on the Problems of Human Evolution.—Letters were read from Sir Charles Ballance and Mr. James Sherren resigning their seats on the Council, such resignations to take effect at the end of the College year in June.—The President reported that a meeting of the Fellows would be held at the College on Thursday, July 1st next, at 2.30 P.M., for the election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Mr. Walter G. Spencer and Mr. Ernest W. Hey Groves, and by the resignation of Sir Charles Ballance and Mr. James Sherren; that notice of the meeting would be given to the Fellows by advertisement and by circular on March 5th; that March 15th would be the last day for the nomination of candidates; and that a voting-paper would be sent on March 30th to every Fellow of the College (except women Fellows) whose address is registered at the College.—Diplomas of Fellow were conferred upon Dr. Harold Burt-White (St. Bart.'s) and Dr. Alan Cameron Maconie (St. Bart.'s), who had previously passed the requisite examinations and have now attained the age of 25 years.—Diplomas of Member were conferred upon 179 candidates (144 men and 35 women) who have passed the requisite examinations and have complied with the by-laws. The following are the names and the medical schools of the successful candidates:—

P. W. A. Agnew, St. George's; N. A. Arnold, Guy's; A. Ashworth, Liverpool; A. L. Banks, Middlesex; C. M. Barker, Cambridge and Univ. Coll.; L. H. Belcher, Guy's; R. J. I. Bell and S. B. Benton, St. Bart.'s; S. Bernstein and M. Bomze, Univ. Coll.; Elsie Boyton, King's Coll.; R. Broomhead, Leeds; A. Byrne-Quinn, St. Thomas's; Irene F. Callender, St. Mary's; A. L. Canby, St. Thomas's, De L. Carey, St. Mary's; S. Chazen, Guy's; H. Childs, Cambridge and St. Thomas's; J. H. Chitty, Oxford and Guy's, J. H. Clapp, London; A. Clark, St. Bart.'s; G. C. W. Clarke, Sheffield; H. N. Collier, Guy's; Violet H. Comber, Univ Coll.; R. V. Cooke, Bristol; W. F. Cooper, Cambridge and St. Bart.'s; A. R. Cox, Guy's; S. T. Davies, Univ Coll.; T. W. Davies, Cardiff; T. E. Davies, St. Thomas's; Hilda C. Dean, Charing Cross; A. E. de Fonseka, Ceylon and King's Coll.; May W. de Livera, Ceylon and Royal Free; G. C. Dewes, Cambridge and St George's; H. V. Dicks, Cambridge and St. Bart's; Mary G. H. Dickson, King's Coll.; Margaret H. Duncan, London; G. H. Dymond, St. Bart.'s; Elaine O. H. Earengey, Univ. Coll.; R. W. B. Ellis, Cambridge and St. Thomas's; D. C. M. Ettles and J. Evans, Guy's; B Fink, Manchester; C. W. Flemming, Oxford and Univ. Coll.; T. D W. Fryer, Cambridge and St. Thomas's; S. W. Gabbe, Cape and St. Thomas's; S. C. Gawne, Liverpool; P. Gibbin, Cardiff; Dorothy Godden, St. Mary's; P. J. Gonsalves, Guy's; A. P. Gorham, Bristol; Agnes H. Gray, Royal Free; D. P. Gray, Middlesex; Margaret K. Green, St. Mary's; W. H. Green, Middlesex; C. R. M. Greenfield, St. Bart's; L. A. N. Greenway, Calcutta and King's Coll.; B J. Griffiths, Cardiff; A A M. Groot, Leyden and Westminster; A. Gross and F P. Guilfoyle, St. Bart.'s; K. H. Hadley, Melbourne and Middlesex; R. N. Hall, Cambridge and St. George's, C. W. Harrison, Los Angeles and St. Bart.'s; L. Hartston, London; H. G. Harvey, St. Thomas's; J. P. Helliwell, St. Mary's, T. R. Hill, Guy's; R. L. Holt, Manchester; H B Hosford, St. Bart.'s; Mary H. M. Huggett, King's Coll; N C. Hypher, London; D. E. Iago-Jones, Cardiff and Middlesex, R. J. Isaac, St. Mary's, G. L. C. Jones, Cardiff and St. Bart.'s; T. Jones, Cardiff; J Kahanas, Berne and London, J. A. Kerr, Birmingham; R. H. Knight, St. Bart's, P D Knowles, St. Mary's, T. P. Lalonde, Bristol, F J. L. Lang, St. Mary's; F. W. Law, Cambridge and Middlesex, D. J. Lawson, Cambridge and St. Thomas's; H J L Le Clerc, St. Thomas's, Anne T Leigh, Manchester, E. A. Lewis, St. George's; R. A. V. Lewys-Lloyd, St. Bart.'s, Leonora M. K. Lines, Charing Cross; T. M Ling, St Thomas's; Edith M. Little, Royal Free; G F H McCormick, Univ. Coll; G. L. M. McElligott, Oxford and St. Thomas's; L. J. McGregor, St. Thomas's; Evelyn T. D. Maclaran, St. Mary's, A. J. McMillan, Middlesex, P. Malpas, Liverpool; Ruth E. Mansfield, Westminster, Mary A. Marshall, St. Mary's; L. O. Martin, Cardiff, S. R. Mathews, Cambridge and Middlesex; H. R. B Mayor, St Thomas's; W. Mayne, Guy's; M. S. Mazhar and S Mellins, Middlesex; R. H. Metcalfe, Cambridge and St. Thomas's, G. C. Milner, Cambridge and London; J. Mintzman, Middlesex; F. E. Montague, St. Thomas's; P. Morton, London; M. Mundy, St. Bart.'s; D. L. P. M. Q. Mylechreest, St. Thomas's; C. D. Nicholson, Middlesex, J. R. P. Norman, Birmingham; G. F. Oakden, Cambridge and St. Thomas's; E. J. O'Keeffe, J. E. J. Palser, and C. H. Parker, London; G. E. G. Peirce, St. Mary's; H. A. Picton, Birmingham; H. P. Pieris, Madras and Middlesex; N. R. Pooler, St. Mary's; W. G. Porter, Guy's; D. C. Price, St. Bart.'s; Winifred E. Probert, Cardiff and Westminster; D. M. Pryce, St Mary's; Muriel A. Pugh, Charing Cross; F. W. F. Purcell, Cape and St. Thomas's; J. H. Randall, Cambridge and Univ Coll.; Marjorie D. Reddan, Royal Free; Margaret G. P. Reed, King's Coll.; H. G. St. M. Rees, Cardiff, J. L. Reeve, St. Bart.'s; A. M. Rhydderch, Cambridge and London; O. Richardson, St. Bart.'s; L. Roberts, Middlesex; Victoria A. Roberts, Royal Free; D. J L. Routh and Audrey E. Russell, Univ. Coll.; J. W. Schabort, Guy's, Gitta Schewel, Hamburg and Westminster; F. L. G. Selby, St. Mary's; T. H. Sellors, Oxford and Middlesex; D. W. Seth-Smith, St. George's; A. de M. Severne, Cambridge and St. Thomas's; W. D. Sheldrake, Guy's, H. J A. Simmons, Cambridge and Middlesex; W. S. Slater, Manchester, E. V. Slaughter, Middlesex; Beatrice G. Smith, Univ. Coll.; L. G. Smith, St. Bart.'s; H. D. Stallard, Cambridge and St. Bart.'s; C. A. Stanley, St. Thomas's, H. L. Steele, Univ. Coll.; A. F. H. Stewart, Guy's; R. K. Stockbridge, Adelaide and London; Dorothy S. Tait, Cambridge and St. Mary's; G. M. Tanner, Cambridge and St Bart.'s, Constance P. Thomas, Cardiff; D. W. R. Thomas, Cardiff and Middlesex; R. Thorpe, St. George's; G. O. Tippett, St. Thomas's; R. S. Tooth, Cambridge and St. Bart.'s, Rose A. H. Traill, Charing Cross; R. M. Walker, Univ. Coll., L. H. F. Walton and H. D. Weatherhead, St. Thomas's; Janet Welch and Violet M. Weston, Royal Free; E. A. White, St. Bart.'s; J. E. D. Williams, Univ. Coll.; J H Williams, Cardiff; H. Williamson, King's Coll.; D. B. Wilson, Cambridge and Birmingham; Jessie Wiltshire and Ada R. Winter, Univ. Coll.; J. Wiseman, Guy's; Joan Worsfold, Royal Free; and Dorothy E. Wright, Univ. Coll.

A series of six museum demonstrations, open to medical practitioners and advanced students, is to be given in the theatre of the College by Sir Arthur Keith and Mr. C. E. Shattock on Mondays and Fridays, from March 12th to 29th inclusive, at 5 P.M. The subjects of the demonstrations will be stated in our Medical Diary of the appropriate weeks.

HUNTERIAN SOCIETY.—The Hunterian Oration, of which the subject will be the Relation of the General Practitioner to Preventive Medicine, will be delivered by Sir George Newman, at 9 P.M. on Monday, Feb. 22nd, in the Mansion House, by kind permission of the Lord Mayor of London.

*Hunterian Society Dinner.*—Dr. Howard Humphris, the President, took the chair at the annual dinner of this Society held at the Hotel Victoria on Feb. 11th. There was a large gathering of Fellows and their guests, amongst whom were the Lord Mayor of London, the Bishop of Kensington, Sir Philip Richardson, M.P., Sir Anthony Hope Hawkins, and Sir Holburt Waring. In proposing a toast to the memory of John Hunter, the President touched on what he termed the lighter side of his life. In his youth Hunter had been "a bit of a lad." "They wanted," he had said, "to send me to the university to learn Latin and Greek and make an old woman of me; but I crushed their ideas like so many vermin." Later he had attained some notoriety as a resurrectionist, and again by driving a team of buffaloes through London. Could that be done to-day, asked the President, or would it be called advertisement? Sir Philip Richardson, proposing the toast of the Society, said that he had never thought that there was much in medicine, but there was a lot in doctors. All the same they were at present the bane of politicians; for the chief cause for anxiety to-day was not the birth-rate, but the death-rate, and the profession ought not to be allowed to invent so many ways of keeping people alive. In reply, the President said that the Society had come through bad times. A few years ago the average attendance had fallen to eight; it was now 80. There were 230 Fellows on the roll and some of the names were the proudest in the profession. The Society was not living in vain. John Hunter, he thought, would not be ashamed of it; he might even offer it his congratulation. Mr. T. H. Openshaw, proposing the toast of "The Lord Mayor," recalled the intimate connexion between the Society and the City. In reply, the Lord Mayor referred to the medical work which was done on behalf of the Corporation as perhaps the most valuable part of those widespread activities of which he was proud to be the temporary representative. Dr. W. Langdon-Brown dealt wittily with the guests in turn, welcoming especially the President's father; the Society had been a mere stripling of 16 summers when the President's father was born 90 years ago. The Bishop of Kensington, replying for the guests, told several admirable stories, as also did Sir Anthony Hope Hawkins, who feared that a tyranny of doctors was developing. Even now medicine was infringing on all other professions, such as the Church and the Law, with its theories and discoveries—perhaps more theories than discoveries. But as they were strong so let them be merciful. "Englishmen of our generation," he said, "like to kill ourselves as we please." Sir Holburt Waring regretted that politicians should insist on the survival of the unfit. Perhaps they should pay more attention to the well-being and survival of the fit. He described the recent press campaign against the General Medical Council as a fine study in mass psychology. Sir Bruce Bruce-Porter paid a high tribute to the Chairman, who briefly replied and proposed a toast to the hon. secretaries, Mr. Mortimer Woolf and Dr. Arthur Westerman, to which Mr. Woolf responded. In the intervals between the speeches there were old-fashioned (and very popular) songs by Mr. Lyell Johnston, and Mr. Joseph Batten was successful at the piano in rousing genuine singing from his cheerful audience.

GLASGOW UNIVERSITY CLUB DINNER.—The annual dinner of the Glasgow University Club, London, postponed from Dec. 4th last, will take place at the Trocadero Restaurant, Piccadilly, on Friday, Feb. 26th, at 7.15 for 7.30 P.M. precisely. The chair is to be taken by Sir Henry Craik, Bart., K.C.B., LL.D., M.P., and Sir Martin Conway, F.R.G.S., M.P., will respond to the toast of The Guests. Any Glasgow University men who, though not members of the club, would like to attend are requested to communicate with the hon. secretaries, 62, Harley House, N.W. 1.

TUBERCULOSIS SOCIETY.—A meeting of this Society will be held to-day, Friday, Feb. 19th, at 8 P.M., at the house of the Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C., when Dr. C. Nicory will read a paper on Tuberculosis in Japan.

OPTICAL SOCIETY.—At the annual general meeting of this Society, held at the Imperial College of Science, on Feb. 11th, the following officers and members of council were elected for the session 1926–27: President: T. Smith, M.A. Vice-Presidents: Inst. Comdr. T. Y. Baker, R.N., B.A.; F. F. S. Bryson, M.A., B.Sc.; R. S. Clay, B.A., D.Sc.; and H. H. Emsley, B.Sc. Treasurer: Major E. O. Henrici, R.E., F.R.A.S. Secretaries: Prof. Alan Pollard, A.R.C.S., A.M.I.E.E., and F. F. S. Bryson, M.A., B.Sc. Librarian: J. H. Sutcliffe, O.B.E. Editor: John S. Anderson, M.A., D.Sc., Ph.D. Members of Council: D. Baxandall, F.R.A.S., A.R.C.S.; W. M. Brett; W. B. Coutts, M.A., B.Sc., F.R.S.E.; A. H. Emerson; E. F. Fincham; J. Guild, A.R.C.S., F.R.A.S.; E. T. Hanson, B.A.; H. C. Raxworthy; J. Rheinberg, F.R.M.S., F.R.P.S.; G. F. C. Searle, Sc.D., F.R.S.; W. Swaine, B.Sc.; and F. C. Watts.

THE LATE DR. F. A. COWARD.—Dr. Frank Augustus Coward, who died on Feb. 5th at his home at Wolverhampton, at the age of 75, at one time had one of the largest practices in Huddersfield. He was a son of the late Dr. J. E. Coward and received his medical education at Aberdeen and Edinburgh, where he took the Scottish triple qualification in 1877. Soon afterwards he joined his father in practice, and eventually succeeded him. About 20 years ago he sold his practice and left Huddersfield for Wolverhampton, where he took an active interest in public life and was prominently identified with the Mothers' and Babies' Welfare Association movement. He was twice married and leaves a widow, two sons, and two daughters.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Feb. 25th, at 5 P.M., a lecture will be given on Some Points in the Treatment of Tuberculosis of the Uro-genital Tract by Mr. Frank Kidd in the lecture room of the Medical Society, 11, Chandos-street, London, W. 1. This will be free to all members of the medical profession.—On the same date Mr. L. B. Barrington-Ward will give a special demonstration in clinical surgery at the Royal Northern Hospital, at 2 P.M., at which all members of the Fellowship and holders of its general course tickets will be welcome.—The following courses will be continued throughout the week: A course in general medicine and surgery at the Queen Mary's Hospital, Stratford; clinical instruction in venereal disease at the London Lock Hospital; and a combined course in diseases of children at the Paddington Green, Victoria Hospital (Chelsea), and Children's Clinic. —During the first fortnight of March there will be a special post-graduate course of demonstrations at the Royal Eye Hospital, the sessions being daily from 3 P.M.—In the early part of March the Westminster Hospital will give a special course in bacteriology.—In the last three weeks of March the Chelsea Hospital for Women will hold a course in gynæcology, including operations, lectures, and demonstrations; and during the last two weeks the Brompton Hospital will hold an all-day course in diseases of the chest.—For the benefit of practitioners with only limited free time, the Hampstead General Hospital will hold a course in general medicine and surgery from 1.30 to 6 P.M.—The Tropical School will begin a course of two sessions weekly on March 10th.—Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal*, may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

SOCIOLOGICAL SOCIETY.—Sir Francis Younghusband will take the chair at a meeting of the society to be held at the rooms of the Royal Society in Burlington House, Piccadilly, London, W., on Tuesday, Feb. 23rd, at 8.15 P.M., when Dr. Binnie Dunlop will speak on the Malthusian Principle and Sociology.

CHADWICK PUBLIC LECTURE.—A lecture on the Activated Sludge Process of Sewage Treatment will be given by Mr. H. T. Calvert, D.Sc., of the Ministry of Health, in the lecture hall of the Institution of Civil Engineers, Great George-street, Westminster, on Friday, Feb. 26th, at 8 P.M.

ROYAL INSTITUTION.—On Feb. 23rd, at 5.15 P.M., Prof. Joseph Barcroft will give the second of three lectures on the Egg, and on Feb. 26th at 9 P.M. Mr. C. Hagberg Wright, LL.D., will deliver an address on Nicolas de Peiresc and His Circle.

PEOPLE'S LEAGUE OF HEALTH.—Amongst newly elected medical councillors to the League are Sir Thomas Horder, Sir Stanley Hewett, Sir Ronald Ross, Sir Henry J. Simson, Dr. F. N. Kay Menzies, and the medical officers of health for Bradford, Manchester, Leeds, Glasgow, and Liverpool.

DR. E. Graham Little, M.P., has been elected a Corresponding Member of the Danish Dermatological Society, and of the Royal Society of Medicine of Budapest. He has also been made an honorary member of the Italian Society of Dermatology and Syphilography.

DONATIONS AND BEQUESTS.—Among other bequests the late Mrs. Emma Pratt, of Leam-terrace, Leamington, left £1000 to Hereford General Hospital; £100 to the Hereford City Nursing and Maternity Society; £1500 to the Municipal Charity Trustees, Hereford, for charities under their control; and £200 to the Royal Midland Counties Home for Incurables, Leamington.

THE LATE DR. J. F. STRICKLAND.—After a long illness Dr. John Fletcher Strickland died at Halifax on Feb. 5th in his fifty-second year. He took his medical degree at Edinburgh in 1896, and held house appointments at Liverpool and Wakefield. Then he moved to Halifax and was amongst the first local medical men to join the Army at the outbreak of war. Unfortunately, his service undermined his health, and though he returned to practise at Booth Town he never regained his strength. Dr. Strickland was of a genial sympathetic disposition, and won many friends amongst his colleagues and patients and in his private life.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.—On Feb. 9th Dr. L. H. Bryson read a paper on the Functional Unit and Reflex Processes, in which he criticised the prevailing teaching that certain reflex activities are controlled by centres, maintaining that in all cases control from the periphery is the only factor regulating them, apart from psychical influence. In a previous communication he had elaborated this view in regard to the cardiomotor and vasomotor reflexes. The functioning of the organs of the body, he said, was regulated according to the requirements of its functional units. The physiological unit consisted of the cell with its capillary supply. The latter could only be efficiently regulated by the cell. The activities of heart and arteries must be determined by the needs of the functional units and be regulated by them; impulses from these peripheral structures must, therefore, determine the activities of the so-called cardiomotor and vasomotor centres. The "centre" was, in fact, nothing more than a focus of integration for impulses received from the functional units at the periphery. The continued belief in specific centres was largely due to the difficulty of demonstrating afferent tracts. This principle of peripheral control acting *through* the central nervous system was incompatible with control *by* the central nervous system, and this applied to all reflex processes. For a reflex to be modified in its course implied that it was imperfect in its design. Discussing the rôle of sensation, Dr. Bryson maintained that between the sensory and motor areas of the cortex there were intermediate neurons upon which sensation arose and conditioning occurred upon the reflex processes. This he termed psychical integration. Elliot Smith had shown that, as evolution advanced, the sensory and motor areas increased in size, but that it was not to these areas that the brain of man chiefly owed its size, but rather to the part interposed between them. Dr. Bryson emphasised the clinical importance of the study of the relationship of reflex processes to sensation and of the psychological problems involved. The paper gave rise to an animated discussion in which Prof. David Morrison and others took part.

UNIVERSITY OF CAMBRIDGE.—The Pinsent-Darwin Studentship in Mental Pathology has been allotted to Dr. R. D. Gillespie, of Cassel Hospital, for research into functional nervous disorders during the next three years.

UNIVERSITY OF LONDON.—A course of three lectures on *Some Principles of Therapeutics* will be given by Prof. D. Murray Lyon at St. Thomas's Hospital Medical School on Feb. 22nd, 23rd, and 24th, at 5.30 P.M. At the first lecture the chair will be taken by Prof. H. MacLean, D.Sc.

A course of four lectures on Active and Passive Immunity will be given by Dr. R. A. O'Brien at University College Hospital Medical School on March 1st, 5th, 8th, and 12th, at 5 P.M. At the first lecture the chair will be taken by Prof. A. E. Boycott, F.R.S.

A course of three lectures on Hygiene will be given in English by Dr. Gustave Monod at the Middlesex Hospital Medical School on March 2nd, 3rd, and 4th, at 5.30 P.M. At the first lecture the chair will be taken by Sir Arthur Newsholme. Admission to all these lectures is free, without ticket.

*Mental Deficiency.*—A course on Mental Deficiency, for medical practitioners, is to be held at the University, Imperial Institute-road, South Kensington, S.W., from May 31st to June 5th. It has been arranged by the University of London Extension Board, in coöperation with the Central Association for Mental Welfare, and is intended more especially for those who are engaged as certifying officers to local authorities under the Mental Deficiency Act, 1913, as school medical officers, as medical officers of institutions, or for any who are definitely concerned with defectives. The course will be based on the requirements of the syllabus for the University's diploma in psychological medicine, and a certificate of attendance will be granted to those who have taken the whole course, including theoretical and practical work. Amongst the lectures will be seven by Dr. A. F. Tredgold on Mental Deficiency, three by Dr. F. C. Shrubsall on Administrative Procedure in the Ascertainment and Treatment of the Mentally Defective, two by Prof. Cyril Burt, D.Sc. on the Psychology of Mental Defectives, and one on Crime and Mental Defect by Dr. Norwood East. The clinical work will consist of visits to special schools and residential institutions in or near London and demonstrations by experts to small groups of students of individual cases of mental defect. The fee for the course, apart from a registration fee of 10*s.* 6*d.*, will be £2 12*s.* 6*d.* No applications will be entertained after May 10th, and it is desirable that they should be sent in as soon as possible if arrangements are to be made convenient for everyone. The Board of Control is prepared to consider applications from local authorities for contributions towards reasonable expenses incurred in sending medical officers to the course. Forms of entry may be obtained from Miss Evelyn Fox, c/o University Extension Dept., University of London, South Kensington, S.W. 7.

*Amendment of Regulations on University Titles.*—The first paragraph of Section A 2 of the Regulations on University Titles (Calendar for 1925–26, p. 320) was amended to read as follows:—Whole time Posts: The guaranteed minimum salary for a University professor giving his whole time to the work of his post shall be £1000 per annum, and the guaranteed minimum salary for a reader giving his whole time to the work of his post shall be £500 per annum; provided that in exceptional circumstances the guaranteed minimum salaries may be not less than £800 and £400 respectively. Part-time Posts: If the duties of the post do not take up the whole time of the occupant the guaranteed minimum salaries for a University professor and University reader shall be £500 and £250 respectively; provided that in exceptional circumstances the guaranteed minimum salaries of part time posts may not be less than £400 and £200 respectively.

*University of London, University College.*—Fourteen entrance scholarships and exhibitions are available for award to students entering University College in October, 1926. Three of them are tenable in any of the five College Faculties, and three are tenable in the Faculty of Medical Sciences only. Most of the scholarships and exhibitions are of the value of £40 a year for three years, but their value may be increased by supplementary bursaries if the circumstances of the scholar or exhibitioner make such a grant necessary. Further particulars may be obtained from the Secretary, University College, Gower-street, W.C. 1.

WE regret to announce the death at Cambridge on Feb. 10th of Dr. Meredith Blake Robson Swann, demonstrator in pathology in the University and Fellow of Gonville and Caius College. It is stated that ten days previously Dr. Swann, who was 32 years of age, pricked his finger whilst making a post-mortem examination.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Unqualified Medical Practice.*

IN the debate last week on a motion by Dr. LITTLE, to inquire into the whole position of irregular practice in medicine and surgery, Colonel SINCLAIR'S remarks were interrupted by a motion for adjournment of the House. Substantially Colonel SINCLAIR said this:

"As the only member of the General Medical Council in this House, perhaps I may be allowed to make a few observations. The General Medical Council has been blamed, not only inside the House, but outside and in the Press, for many of its decisions. I think that many who have criticised it in a hostile sense have not taken the trouble to consider its mode of procedure, how the cases come before it, and how members receive and weigh the evidence and come to a decision. Moreover, its clemency is much greater than many Members of the House understand. Many of those who are deprived of diplomas are only deprived for one year or thereabouts, and, if not guilty of the offence again, they are reinstated in many cases within the year.

"The General Medical Council does not proceed against osteopaths and chiropractors. It really cannot recognise them, because it has no means of inspecting their skill. It has no means of understanding or estimating the nature of the education furnished or the standards of education and examinations which they take. It would not be in the public interests to take the American diplomas at their face value. Many of these are granted by organisations some of which are of a proprietary nature and are not recognised in the United States. It would be hazardous to include all these practitioners in the general register unless there was some provision made for inspecting the colleges, the nature of the instruction given, and of the examination passed.

"In the case of dentists, when the country some years ago was flooded by a large number of unqualified men, the Dentists Act of 1921 was passed for the protection of the public. It was then made, with great severity, a penal offence to practise dentistry unless the name of the dentist was on the Dental Register. Therefore, it appears to me to be right in the public interest that there should be an inquiry respecting the persons entitled to practise medicine and surgery, including manipulative surgery and plastic surgery, lest great damage should be done to the suffering public by unqualified people carrying out manipulative surgery with great energy and even rough handling. Practitioners who desire to practise manipulative surgery should provide a guarantee that they have been properly instructed in the anatomy of the human body, physiology and pathology, so that they would be able to distinguish those patients to whom they ought not to apply manipulative surgery, and who ought to be treated by other means. It ought to be borne in mind that the General Medical Council does not put a veto on the class of practice which its registered members may adopt. All that it requires is that they shall have been trained in medicine, surgery, and midwifery. They may practise manipulative surgery, homœopathy, or other forms of service provided they show that they have graduated at some recognised institution, and that they have a thorough knowledge of anatomy, physiology, and pathology.

"The General Medical Council is a much maligned body. It has been suggested that it ought to be reinforced by the addition of lay members. We have no objection to the addition of lay members. The machinery exists already for their introduction. If the Privy Council would use its power of nomination for the purpose of placing lay members on the General Medical Council, it is quite within its competence to do so. Moreover, the universities of the Kingdom might send lay professors to the Council instead of medical members. That is within their competence. The difficulty is that people cannot be got to take an intelligent interest in the work of the General Medical Council unless they are medical men, because three-fourths of the work of the Council has to do with medical education and registration. It is difficult for the laity really to understand and to keep a sustained interest in the regulations of the medical curricula and the medical examinations.

"Much has been said with respect to the cures effected by the bone setters. I do not deny that the manipulative surgeons have done good work, but the general medical profession have done equally good work."

### *New Midwives' Legislation.*

The Bill to amend the Midwives Acts and for other purposes, introduced by Lieut.-Colonel FREMANTLE in the House of Commons on Thursday, Feb. 11th, is in two parts. It provides (*a*) for the better control of unqualified midwives, for decreasing the deficit in the funds of the Central Midwives Board, which is due to the inclusion in the roll of midwives published annually of the names of large numbers of women who for one reason or another are not practising; for the payment of compensation to midwives who are suspended from practice through no fault of their own; for fixing a time limit for the rendering of claims for fees by medical practitioners called in by midwives on emergencies; and certain other purposes; and (*b*) for the registration and inspection of maternity homes by the councils of counties and county boroughs. The Bill is supported by Major J. W. HILLS, Mr. ARTHUR GREENWOOD, and Sir HENRY SLESSER.

## HOUSE OF COMMONS.

### WEDNESDAY, FEB. 10TH.

### *Treatment of Encephalitis Lethargica.*

Mr. AMMON asked the Minister of Health whether the arrangements made between his department, the London County Council, and the Metropolitan Asylums Board for the treatment of encephalitis lethargica cases was for medical care only.—Sir K. WOOD replied: My right hon. friend assumes that the hon. Member is referring to the arrangements made by the Metropolitan Asylums Board for the institutional treatment of children suffering from the mental after-effects of encephalitis lethargica. These arrangements provide for the ordinary hospital accommodation of the patients and all necessary treatment and medical care.

Mr. AMMON asked the Minister of Health whether his attention had been called to the case of a young man who was charged with theft at the Lambeth police-court on Jan. 5th last, and was found to be suffering from the after-effects of encephalitis lethargica; and whether, in view of the increase of such cases, he would take steps to consider ways and means of providing adequate treatment and training for the victims of this and other brain troubles?—Sir K. WOOD replied: The answer to the first part of the question is in the affirmative. As regards the second part, the question of the best means of providing for such cases as that mentioned is receiving careful consideration by the department concerned.

### *Mental Condition of Juvenile Offenders.*

Mr. AMMON asked the Home Secretary what was the standing or qualifications demanded of medical men engaged in prisons and remand homes to examine and report as to the mental condition of juvenile offenders brought before the magistrates.—Sir W. JOYNSON-HICKS replied: At places of detention to which young persons under 16 are remanded medical attendance is usually afforded by a doctor in general practice, but where mental trouble is suspected the case might be referred to a school medical officer or other specially qualified doctor. Offenders over 16 are remanded to prisons where the medical officers are experienced general physicians and surgeons of good qualifications, with special experience of insanity and mental deficiency. I may add that the medical examination of young offenders is being considered by the committee which I appointed last year to inquire into the treatment of young offenders.

### THURSDAY, FEB. 11TH.

### *Artificial Limbs.*

In reply to questions by Mr. T. HENDERSON, Mr. PARKINSON, and Mr. WHITELEY on the supply of artificial limbs to ex-Service men,

Major TRYON, Minister of Pensions, said: The present arrangements for the supply of artificial metal legs are working quite satisfactorily and I am not prepared to reconsider them. The few cases in which representations are made for a special make of limb not covered by the present contracts are considered by a board of surgeons constituted for the purpose, and where necessary, in accordance with their advice, arrangements are made for the supply of an artificial limb similar to that previously used by the man though not covered by the present contract.

### *Indecent Literature.*

Sir N. GRATTAN DOYLE asked the Home Secretary whether he had received complaints from members of the medical profession and others regarding the transmission through the post of descriptive and illustrated circulars advertising various kinds of contraceptives; whether the Public Prosecutor had been consulted with reference thereto, and, if so, with what result; whether he would say if existing legislation was sufficient to protect the public against the effects of this traffic; and what steps he proposed to take in order to deal with it.—Sir W. JOYNSON-HICKS replied: Yes, Sir. I have received numerous complaints and the Director of Public Prosecutions has given the subject close attention in conjunction with my department. He has taken, and will continue to take, action in cases which appear to him to involve a contravention of the law, but the success of such proceedings depends upon the magistrates being satisfied that the postal matter complained of is in fact indecent, and I am afraid that the divided state of opinion on the subject of birth control has been to some extent reflected in the decisions given. I know of no further steps which I could usefully take.

### *Birth-rate and Birth Control.*

Sir N. GRATTAN DOYLE asked the Minister of Health whether, in view of the progressive decline in the birth-rate of this country, he could give the percentage birth-rate during last year and the same rate for the principal countries in Europe.—Mr. N. CHAMBERLAIN replied: The following is the information asked for. As the 1925 birth-rates for foreign European countries are not yet available, the figures asked for are given for the most recent years for which information has been received:—

*Birth-rate per 100 Population.*

| | | | |
|---|---|---|---|

* Provisional.

### *Small-pox in Durham.*

Mr. LANSBURY asked the Minister of Health how many cases of small-pox had occurred in the county of Durham since the present outbreak started down to the week ending Feb. 6th, showing the number of cases each week; how many deaths, if any, had taken place; would he give the names of the towns, districts, and villages where the outbreak was most severe; and what steps he had taken to discover the cause of the outbreak and the reasons which had led to so rapid a spread of the disease.—Mr. N. CHAMBERLAIN replied: The total number of cases of small-pox which have been notified in the county of Durham from Jan. 1st, 1925, to Feb. 6th, 1926, is 1960. In two instances small-pox was entered on the death certificate as one of the causes of death. Numerous visits have been paid to the affected districts by medical officers of my department for the purpose of advising and assisting the local authorities, and their officers and their reports indicate that the outbreak may be attributed to the spread of the disease from other infected areas and that the present prevalence is in large measure due to the neglect of vaccination and in some districts to the lack of adequate hospital accommodation. The following is a statement showing the number of cases notified each week during the period from Jan. 1st, 1925, to Feb. 6th, 1926, and the names of the towns and districts where the disease is most prevalent:—

1925: Week ended Jan. 24th, 1; 31st, 3; Feb. 7th, 2; 21st, 2; 28th, 1; March 7th, 1; 14th, 2; 21st, 31; 28th, 3; April 4th, 8; 11th, 8; 18th, 8; 25th, 6; May 2nd, 7; 9th, 10; 16th, 4; 23rd, 4; 30th, 3; June 6th, 2; 13th, 4; 20th, 8; 27th, 11; July 4th, 19; 11th, 43; 18th, 17; 25th, 20; Aug. 1st, 7; 8th, 18; 15th, 9; 22nd, 8; 29th, 10; Sept. 5th, 9; 12th, 11; 19th, 12; 26th, 12; Oct. 3rd, 10; 10th, 11; 17th, 23; 24th, 29; 31st, 42; Nov. 7th, 37; 14th, 49; 21st, 40; 28th, 70; Dec. 5th, 80; 12th, 86; 19th, 119; 26th, 104.

1926: Week ended Jan. 2nd, 98; 9th, 138; 16th, 139; 23rd, 177; 30th, 182; Feb. 6th, 213.

No cases were notified for the weeks ended Jan. 3rd, 10th, and 17th, and Feb. 14th, 1925, respectively.

The areas where the disease is most prevalent are: Gateshead C.B., Blaydon U.D., Chester-le-Street U.D., Whickham U.D., South Shields C.B., Auckland R.D., Chester-le-Street R.D., Easington R.D., Houghton-le-Spring R.D., Lanchester R.D., Sunderland R.D., Spennymoor U.D.

Mr. BATEY: Is the right hon. gentleman aware that the districts that are the worst affected are the districts where the men have been most impoverished?

Mr. CHAMBERLAIN: No, Sir; I do not think so.

Commander WILLIAMS: Can the right hon. gentleman say what percentage of these cases have been vaccinated?

Mr. CHAMBERLAIN: I cannot answer that without notice.

Mr. LANSBURY: Is it not a fact that in the county of Durham just now in all the districts poverty is very prevalent, and is it not a proved fact that disease attacks people whose physique is lowered through want of food?

Mr. CHAMBERLAIN: I think it would be very difficult to draw any safe deductions from the figures in my possession, but they certainly do not bear out the suggestion made the other night that the cessation of poor relief in a particular union was the cause of the special prevalence of disease in that union, seeing that in that particular union the prevalence of disease is considerably less than in an adjoining union where there has been no such cessation.

Mr. LAWSON: How does the right hon. gentleman account for the fact that in the areas where there has been most unemployment the outbreak of small-pox is most prevalent?

Mr. CHAMBERLAIN: Possibly there has been less vaccination there.

### *Physique and Health of Air Force Recruits.*

Mr. Hore-Belisha asked the Secretary of State for Air (1) how many men were accepted in the year 1925 for His Majesty's Air Force, and how many were rejected on account of some physical deficiency; and (2) what percentage of applicants were rejected for the Air Force in 1925, and what the principal defects were, giving the proportions to the total number of rejections.—Sir S. Hoare replied: The number of men passed fit for service in the Air Force was 2883, the number rejected as medically unfit was 3111, or a percentage of 51·10 of those medically examined. The principal causes of rejection as revealed by examination by Service medical officers were as follows:—

| | Per cent. | | Per cent |
|---|---|---|---|
| Defective teeth .. | 13·0 | Diseases of lungs | 8·1 |
| Diseases of the heart* . | 12·1 | Defects of vision | 7·3 |
| Poor physique.. .. | 9·5 | Defects of extremities.. | 2·3 |
| *Diseases of the ears* .. | 8·8 | *Other causes* | 30·0 |
| Deformities of feet .. | 8·6 | | |

* Valvular disease or disordered action.

### *Salt on Snowy Streets.*

Sir Alfred Butt asked the Minister of Health whether his department had conducted investigations into the effect on the health of the public from the use of salt on snowy streets; how long the resultant liquid remained below the freezing point of water; and whether any representations had been made to local authorities on the subject.—Mr N. Chamberlain replied: The model by-laws issued by my department for the prevention of nuisances require, when salt is thrown upon snow on a footway, the resultant product shall be removed as soon as possible. These by-laws have been adopted by a large number of local authorities. I understand that no investigation has been conducted by my department on the particular point mentioned by my hon. friend, and I am advised that it would be most difficult to devise experiments from which reliable conclusions could be drawn.

### *Naval Leave in Small-pox Areas.*

Mr Bromfield asked the First Lord of the Admiralty why Fleet orders had been issued giving a recapitulation of the restrictions in regard to leave for officers and men proceeding to any town or district in which an outbreak of small pox has been notified, seeing that all the officers and men in question had been vaccinated at least once, and many of them several times, since joining the Service.—Mr. Davidson replied: Restrictions in regard to leave for officers and men in districts where small-pox is prevalent are necessary in view of the fact that, although every reasonable precaution is taken to ensure the protection of every individual in the Navy against this disease by vaccination, there still must be a certain proportion unprotected, either by oversight or on the grounds of conscientious objection, to which must be added recent entries who have not yet undergone protection by vaccination. In addition, H.M. dockyard employees are not under the same control as naval personnel as regards vaccination, and consequently a large proportion of them are non-immune, and as naval personnel and these employees are intimately associated, infection might be carried either by a person in the early stages of small-pox or by the clothing of one who has been recently in contact with a case. It is considered that no precaution should be neglected to prevent a case of small-pox occurring in one of H.M. ships or establishments, as, apart from *the menace to health*, *there* is the question of the great expense incurred in isolation and destruction of clothing, bedding, etc., necessary owing to the highly infectious nature of this disease. In addition, there is the inconvenience and expense of *keeping* all *contacts of a case in* isolation and under observation for 14 days.

### *Midwives and Maternity Homes Bill.*

Lieut.-Colonel Fremantle presented a Bill to amend the Midwives Acts 1902 and 1918, and to provide for the registration of maternity homes. The Bill was read a first time.

## Monday, Feb. 15th.

### *Board of Lunacy Control.*

The House went into Committee of Supply on a supplementary estimate for £26,600 for the salaries and expenses of the Board of Control (Lunacy and Mental Deficiency) in England, and for grants in respect of maintenance of certain ex-Service mental patients and certain damages and costs in a legal action.

Mr. Pethick-Lawrence called attention to the sum of £2800 which appeared in the estimate in respect of the case of Harnett v. Bond. In this case, he said, the plaintiff, Mr. W. S. Harnett, brought an action against Dr Bond, a Commissioner of the Board of Control, and another, on the ground of alleged wrongful imprisonment as a lunatic. He was released according to the statement of the medical officer of the asylum on 28 days' leave. He found that his brother was in charge of his property and went to the Board of Control to have the matter investigated. While he was there he interviewed a member of the Board, Dr. Bond, who detained him and sent him back to the asylum, where he remained in custody for eight years. The jury, after hearing the case, awarded £25,000 damages against Dr. Bond and £5000 against the medical officer of the asylum. On appeal the Court of Appeal ordered a new trial as between the plaintiff and Dr. Bond. The plaintiff appealed against this judgment to the House of Lords who dismissed the appeal. At this stage the Board of Control offered a sum of £250 as damages and £2500 in respect of plaintiff's costs. After negotiations this offer was accepted. The case was a serious one, as this unfortunate man had not merely suffered eight years' detention as a lunatic when he was sane, but he had also spent a sum of over £25,000 to obtain his rights. The taxpayers who had had to pay the sum *of £3000 or £4000 already, was now called upon to pay* a further sum of £2800.

Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health), in reply, said he thought that the hon. Member had been wholly misinstructed as to the facts of the case. He (Sir K. Wood) intended to be very guarded in his reply, as he understood that Mr. Harnett had brought another action in the King's Bench Division against the doctor who gave the first certificate of his insanity.

Mr. Short asked the Chairman (Mr. Hope) if it was right for the Committee to discuss the matter, seeing that it was again to be brought into court. He suggested that the vote should be withdrawn pending the final decision of the case.

Sir Douglas Hogg (Attorney-General) said it was possible to discuss the vote, which was necessary to carry out the arrangement come to in the first action, without touching on the issue in the forthcoming case.

The Chairman said that in the circumstances it would be better to withdraw the vote until later to allow him to consider the situation, as he would not like to rule on the matter right off in case it might be made a precedent.

The vote was postponed accordingly.

### *The Dentists Act.*

Mr Barnes asked the Prime Minister whether he was aware that Section 6 of the Dentists Act, 1921, was operating in such a manner as to exclude corporate bodies of working-*class constitution whose boards of management did not* include qualified dentists from supplying dental service to their members; and whether he would introduce legislation which would remove this exclusion.—Sir K. Wood replied: My right hon. friend understands that there is nothing in this Section, as interpreted hitherto, to prevent any coöperative society or similar body from arranging for the dental treatment of its members, provided it does not seek any profit in so doing, and he cannot see any necessity for amending legislation.

### *Training of Midwives in Scotland.*

Captain Wedgwood Benn asked the Prime Minister whether he had considered the possibility of extending to Scotland the provisions for grants in aid of the training of midwives, laid down in Mem. No. 102, M.C.W., issued by the Ministry of Health.—Sir John Gilmour (Secretary of State for Scotland) replied: I have considered the question of extending to Scotland the provisions for grants in aid of training midwives, but I have not seen my way to make represent*ations to the Treasury on the subject*, because there is no actual or prospective shortage of midwives in Scotland.

### *Small-pox and Vaccination.*

*Sir* William Davison *asked the Minister of Health* whether he could give the House any information as to the progressive increase of small-pox in this country since the war; and whether such increase coincided with a like increase in the number of persons who were not protected by vaccination.—Sir K. Wood replied: The number of cases of small-pox in England and Wales has increased from 311 in 1919 to approximately 5300 in 1925. My right hon. friend has no information as to the number of persons who are not protected by vaccination, but there can be little doubt that it has been steadily increasing since the war, although it is generally found that considerable numbers of persons present themselves for vaccination when any serious outbreak of small pox takes place.

## Tuesday, Feb. 16th.

### *Grants to Maternity Institutions.*

Mr Neil Maclean asked the Secretary for Scotland the amount of grant paid to English maternity institutions, whether any similar grant was paid to similar institutions in Scotland; and, if not, whether, in view of the new regulations which come into force in Scotland on May 1st 1926, increasing the cost and extending the period of maternity nurses, he would make representations to the Treasury for a proportionate grant to be made to Scottish maternity institutions.—Sir J. GILMOUR replied: With regard to the first part of the question I would refer the hon. Member to the Minister of Health. As regards the second part, under the Maternity Service and Child Welfare schemes in Scotland, no payments of grant are made directly to maternity institutions, but where a local authority has made approved arrangements to a voluntary institution, or itself provides an institution, the approved cost ranks against the maternity and child welfare grant. In reply to the last part of the question, as the hon. Member is doubtless aware, the whole question of the finances of voluntary hospitals in Scotland has been the subject of a remit to a special committee whose report I have just received.

### *Miners' Nystagmus.*

Mr. WILFRID PALING asked the Secretary for Mines the number of coal-miners certified as having nystagmus in each of the years from 1921 to 1925 inclusive.—Colonel LANE-FOX replied: The number of certificates of disablement given by certifying surgeons was: In 1921, 1986; in 1922, 4047; in 1923, 1050; in 1924, 3446. The figures for 1925 have not yet been compiled by the Home Office.

Sir H. BARNSTON, on behalf of the Home Secretary, also replied: The number of new cases of miners' nystagmus for which compensation was paid under the Workmen's Compensation Acts in each of the years 1921 to 1924 was as follows: 1913 in 1921; 4092 in 1922; 3883 in 1923; and 3271 in 1924. The figures for 1925 are not yet available.

### *Lead Paints Protection Bill.*

Lieut.-Colonel HENDERSON asked the Home Secretary whether he proposed to reintroduce the Lead Paints Protection Bill this session.—Sir W. JOYNSON-HICKS replied: I hope to reintroduce this Bill very shortly.

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Feb. 22nd.—8 P.M., ODONTOLOGY. Mr. F. Coleman: An Ivory Exostosis of the Mandible Simulating a Tooth. Sir Frank Colyer: Abnormal Teeth from the Region of the Premaxilla.

TUESDAY.—5.30 P.M., MEDICINE, ELECTRO-THERAPEUTICS, SURGERY, AND LARYNGOLOGY. Dr. L. S. T. Burrell, Dr. Stanley Melville, Mr. J. E. H. Roberts, and Mr. Somerville Hastings: Open discussion on the Diagnosis and Treatment of Intrathoracic New Growths.

WEDNESDAY.—5.15 P.M., COMPARATIVE MEDICINE. Dr. P. H. Manson-Bahr: The Relation of Wild Animals to Certain Diseases of Man. Discussion opened by Dr. Andrew Balfour.

THURSDAY.—8.30 P.M., UROLOGY. Prof. Hugh MacLean: The Testing of Renal Function and the Treatment of Renal disease. Discussion.

FRIDAY.—4.30 P.M., STUDY OF DISEASE IN CHILDREN. Clinical Meeting at Paddington Green Children's Hospital, W. 8 P.M., EPIDEMIOLOGY AND STATE MEDICINE. Dr. M. Greenwood and Prof. W. W. C. Topley: Experimental Epidemiology: Some General Considerations.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Feb. 22nd.—8.30 P.M., Discussion on the Ætiology and Diagnosis of Gall-stones, to be introduced by Sir Humphry Rolleston, Bart., followed by Mr. R. P. Rowlands and Dr. Robert Knox.

WEDNESDAY.—9 P.M., Dr. E. Farquhar Buzzard: Principles of Treatment in Relation to Diseases of the Nervous System. (Second Lettsomian Lecture.)

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, Feb. 26th.—8.30 P.M., Papers will be read by Sir Thomas Horder and Dr. F. W. Price on Syphilis of the Heart and Aorta, more Especially the Early Signs and Symptoms. A discussion will follow.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, Feb. 22nd.—5 P.M., Sir Arthur Keith: The Taungs Anthropoid: Its Zoological and Geological Position.

WEDNESDAY.—5 P.M., Fossil Anthropoids of Europe and of Asia.

FRIDAY.—5 P.M., The Kivu Gorilla and its Bearing on the Problems of Human Evolution.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Feb. 26th.—4 P.M., Mr. Harold Kisch: Frontal Sinus Disease and its Treatment.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: FEBRUARY–MARCH, 1926.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, Feb. 22nd.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., The Neuro-Muscular System, I., The Action of Muscles: Dr. Kinnier Wilson.

TUESDAY, Feb. 23rd.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Treatment of Head Injuries: Mr. Armour.

THURSDAY, Feb. 25th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Neuro-syphilis, I.: Dr. Riddoch.

FRIDAY, Feb. 26th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., Surgery of the Peripheral Nerves: Mr. Sargent.

The fee for the Course, including Pathology lectures, is £5 5*s*. For those who hold Perpetual Tickets the fee is £3 3*s*.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. GREENFIELD, Dean of Medical School.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 22nd, to SATURDAY, Feb. 27th.—Fellowship of Medicine lecture, at the Medical Society, 11, Chandos-street, W. Thursday, 5 P.M., Mr. Frank Kidd: Some Points in the Treatment of Tuberculosis of the Uro-Genital Tract. Free to members of the medical profession. Special Clinical Surgery Demonstration, at Royal Northern Hospital, at 2 P.M., by Mr. L. B. Barrington-Ward.—QUEEN MARY'S HOSPITAL, Stratford, E. Special Post-graduate Course in General Medicine and Surgery. Operations, Surgical Demonstrations, Medical Demonstrations, Lectures, and Demonstrations in the Special Departments. Daily 10–5 P.M.—LONDON LOCK HOSPITAL, Dean-street, W. Clinical Course. Instruction daily in the O.P. Department.—COMBINED CHILDREN'S COURSE, Paddington Green Hospital, Victoria Hospital (Tite-street, Chelsea) and the Children's Clinic (Cosway-street, N.W.). Morning and afternoon sessions daily. Further information from the Secretary of the Fellowship of Medicine.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.

WEDNESDAY, Feb. 24th.—Dr. Harrison: Tests of Pancreatic Efficiency.

THURSDAY.—4 P.M., Mr. O. L. Addison: Some Surgical Infections of the Kidney.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

THURSDAY, Feb. 25th.—5 P.M., Mr. L. H. S. Williams: Acute Abdominal Pain in Pregnancy.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.

WEDNESDAY, Feb. 24th.—5.30 P.M., Mr. J. G. Turner: Biological Factors of "Regulation."

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THURSDAY, Feb. 25th.—4.15 P.M., Dr. Charles Singer: The History of Small-pox (last of four lantern lectures, open to medical students of the University of London).

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Feb. 22nd.—10 A.M., Surgical Out-patients: Mr. W. E. Tanner. 10.30 A.M., Gynæcological Operations: Mr. A. E. Giles: Throat, Nose and Ear Operations: Mr. W. Ibbotson. 2 P.M., Medical, Surgical, and Gynæcological Clinics, Operations. 6.30 P.M., Venereal Department.

TUESDAY.—2 P.M., Medical, Surgical, Throat, Nose and Ear Clinics, Operations. 4.30 P.M., Dr. W. Jenkins Oliver: Some Skin Diseases of Childhood.

WEDNESDAY.—10.30 A.M., Surgical Operations: Mr. E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 5.30 P.M., Venereal Department.

THURSDAY.—10.30 A.M., Dental Out-patients: Mr. E. S. Pierrepont. 2 P.M., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

FRIDAY.—10.30 A.M., Eye Operations: Mr. N. Fleming, 2 P.M., Surgical, Medical, and Children Clinics, Operations. 3 P.M., Gynæcological Clinic. 6.30 P.M., Venereal Department.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

TUESDAY, Feb. 23rd.—5 P.M., Dr. J. H. Sequeira: Tuberculosis Cutis (2).

THURSDAY.—5 P.M., Dr. Wilfrid Fox: Cutaneous Syphilis (1).

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

TUESDAY, Feb. 23rd.—3.30 P.M. (at the Jessop Hospital), Mr. King: Some Gynæcological Difficulties.

FRIDAY.—3.30 P.M. (at the Royal Infirmary), Prof. Mellanby: Some Points in Clinical Therapeutics.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE.

FRIDAY, Feb. 26th.—4.30 P.M. (at Whitworth-street West Branch), Dr. D. Dougal: The Indications for the Induction of Labour and the Methods Employed.

# Appointments.

CAMPBELL, J. G., M.D. R.U.I., has been appointed Medical Officer of Health for Saltcoats.

CREANY, R., Junr., L.R.C.P. Lond., M.R.C.S., Senior Medical Officer to the Bengal and North Western Railway.

KENNEDY, T. D., M.B., Ch.B. Edin., District Medical Officer (Medical Referee) to the Scottish Board of Health.

SHERA, A. G., M.D., B.Ch. Camb., L.R.C.P. Lond., M.R.C.S., Pathologist (Part-time) to the East Sussex County Mental Hospital, Hellingly, Sussex.

SOOTHILL, V. F., M.D., B.Ch. Camb., D.P.H., Medical Officer of Health to the City and County of Norwich.

St. Thomas's Hospital: SOUTAR, K. A., M.B., B.S. Lond., CHEESMAN, W. E., M.B., B.Ch. Cantab., MILLER, A. K., M.R.C.S., L.R.C.P. Lond., EDWARDS, J. L., M.B., B.Ch. Cantab., LENNANE, G. A. Q., M.R.C.S., L.R.C.P. Lond., MILLER, N. A., M.R.C.S., L.R.C.P. Lond., WALTER, A. G., M.R.C.S., L.R.C.P. Lond., TEDI, E. A., M.R.C.S., L.R.C.P. *Swansea Hospital.*—H.S. £150.
*West London Hospital, Hammersmith, W.*—H.P. and two H.S.'s. Each at rate of £100.
*Western Ophthalmic Hospital, Marylebone-road, N.W.*—Sen. and Jun. H.S.'s. At rate of £150 and £100 respectively.
*York County Hospital.*—H.S. £150. Also H.S. for Eye, Ear, and Throat Dept. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacancies for Certifying Factory Surgeons at Strathaven (Lanarkshire), Craven Arms (Salop), Sherburn-in-Elmet (Yorks, W. Riding), and at Wartle (Aberdeenshire).

# Births, Marriages, and Deaths.

## BIRTHS.

JORY.—On Feb. 15th, at a nursing home, to Yvonne, wife of Philip J. Jory, D.S.O., M.B., F.R.C.S., of a son.

MOORE.—On Feb. 9th, at Ickleton, Great Chesterford, Essex, the wife of Dr. J. York Moore, of a daughter.

PATERSON.—On Feb. 5th, at Queen Anne-street, W., Dorothy, the wife of Dr. Donald Paterson, of a son.

SCHULZ.—Talitha Schulz, daughter of Muriel Wrinch and H. H. Schulz, M.A., M.R.C.S., L.R.C.P., born on Dec. 18th, 1925, at The Athelstan House Maternity Home, Feltham, Middlesex.

## MARRIAGES.

COLTART—HAWKE.—On Feb. 11th, at St. Mary's Church, Shortlands, Kent, John Gilchrist Coltart, M.B., Ch.B., of Park Langley, Beckenham, Kent, to Dora Phyllis, daughter of Dr. and Mrs. Hawke, Shortlands, Kent.

GRAY CLEGG—NIGHTINGALE.—On Feb. 10th, at the Wesleyan Methodist Church, Manchester-square, W., by the Rev. A. Gordon James, John Gray Clegg, M.D., B.S., F.R.C.S., &c., of Manchester, to Edith Anna Nightingale, of London.

MILLER—BATCHELLER.—On Feb. 10th, at St. Peter's, Maidstone, Thomas Mackinlay Miller, *M.C.*, of Grosvenor-road, Tunbridge Wells, late R.A.M.C., to Freda, youngest daughter of Robert Batcheller, of Engadine, Maidstone.

## DEATHS.

AIR.—On Feb. 12th, at Tennison-road, South Norwood, Alexander Cummings Air, L.R.C.P. Lond., M.R.C.S. Eng., in his 81st year.

BATT.—On Feb. 14th, at The Hill, Witney, Oxon, Charles Dorrington Batt, M.B., J.P., aged 80 years.

HAYNE.—On Feb. 14th, 1926, Louis Brightwell Hayne, M.B.E., M.D. Cantab., aged 50 years, of Sheen House, Harrogate, second son of the late Henry Hayne, of The Ferns, Tunbridge Wells, and Mark Cross, Sussex, and of Mrs. Hayne. Was interred at the Borough Cemetery, Tunbridge Wells, on Wednesday, Feb. 17th.

MISKIN.—On Feb. 9th, at Harrington-road, Brighton, George Albert Miskin, M.D., aged 84.

NORTON.—On Feb. 8th, at St. Leonards-on-Sea, Algernon Charles Wodehouse Norton, M.D., Crimean veteran, son of the late Dr. Robert Norton, in his 93rd year.

OLIVER.—On Feb. 10th, at his sister's house, Beare Green, after a very short illness, Matthew Baillie Oliver, O.B.E., F.R.C.S., of Harley-street.

RAYNER.—On Feb. 8th, at The Lodge, Hythe, Kent, Henry Rayner, M.D., of Upper Terrace House, Hampstead, aged 84.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

MIDDLESEX HOSPITAL ANNEXE.—The new Middlesex Hospital Annexe in Cleveland-street, London, W., will be opened on Tuesday, Feb. 23rd, at 3.30 P.M., by the Minister of Health.

SYDNEY RINGER MEMORIAL LECTURE.—*Regulation of the Coronary Circulation* will be the subject of the Sydney Ringer lecture at University College Hospital Medical School, which is to be delivered by Dr. G. V. Anrep on Thursday, March 4th, at 5 P.M. The lecture will be open to medical practitioners and students.

# Notes, Comments, and Abstracts.

## INDIAN SCIENCE CONGRESS.

THE thirteenth annual meeting of the Indian Science Congress, under the auspices of the Asiatic Society of Bengal, took place in Bombay during the first week in January. Sectional meetings were held in agriculture, medical and veterinary research, chemistry, botany, zoology, mathematics and physics, geology, anthropology and psychology.

In a country like India, with such extremes of climate, such serious epidemics of disease, such varying conditions of living, such different standards of health in the several races which inhabit the country, medical research is of peculiar importance and interest. Research activities have until recently been confined to the few, but the crowded benches at the meetings of the Indian Science Congress at Bombay justify the hope that the practitioner and even the general public are beginning to take a stronger interest in the solution of many problems of vital importance to India. In a presidential address, Mr. Albert Howard, Director of the Institute of Plant Industry, Indore, dealt with the connexion between agriculture and science. Speaking of irrigation, he mentioned that there are many differences between irrigated crops and those grown under natural conditions, and that plants and animals on irrigated areas do not have the same well-being as those living under natural conditions, while there is a tendency among the people for intense malaria to develop. He raised the question: Is this malaria due to increased opportunity for mosquito breeding, or is it that the nutritive and vitamin value of the crops grown under canal irrigation is less than under natural conditions, and is the lowered resistance of the people the cause of the increased malaria? He believed that McCarrison was on the eve of throwing light on these questions when his investigations were cut short by Government retrenchment. The presidential address to the medical section was given by Dr. Raw, one of the private practitioners of Bombay. Great stress was laid on the importance of the general practitioner interesting himself in research, and endeavouring to maintain the high standard of work which has hitherto been held by the men of the I.M.S. He lamented the loss sustained by Bombay a few years ago, when the Bombay Tropical School was abandoned after all arrangements for its opening had been concluded and much expenditure incurred. Had the school been now in existence, he said, the whole atmosphere of Bombay as regards research would be altered.

Many interesting papers were read. One by Major Russell showed the working out of a population growth curve for the Madras Presidency on the formula given by Prof. Raymond Pearl and Prof. Read of the Johns Hopkins University. This, he said, has been tested by the growth of populations in many European countries where censuses are regularly taken and has been proved correct, and when applied to Madras it indicated that the population is within a million or two of its maximum expansion and that some violent upheaval or epidemic may be anticipated to keep it within possible limits. Another paper by the same author described a cholera periodicity in India occurring every six years. Some papers were read on plague vaccine and prophylactic. It was mentioned more than once that the Haffkine plague prophylactic has held first place for 20 years and has never been improved on by later workers. Bombay is beginning to realise what India owes to Haffkine, and has marked its grateful if over-tardy recognition by altering the name of the Bombay Bacteriological Laboratory to the "Haffkine Institute."

A considerable part of one morning was given up to an account of the research work on sprue now being carried on at the Haffkine Institute. The analysis of the gastric and intestinal contents, urine and blood was discussed. It seemed to be generally considered that the disease was probably a general inflammatory condition of the digestive mucous membrane not caused by yeasts, possibly of infective origin, and with a definite lowering of the ionic calcium of the blood. A paper on anæmia led to a discussion on the pernicious anæmia of pregnancy, which is very prevalent in Bombay. An interesting paper dealt with the development of malaria in connexion with the land reclamation scheme in Bombay. A large area of sea is being reclaimed by means of dredging operations, clay from the harbour being poured through pipes on to the chosen surface of sea. As the clay settles, an uneven surface is formed with many pools of sea water in which mosquitoes breed freely. The coolies camp on the outskirts and are no doubt heavily infected. In spite of this the antimalarial measures have been so thorough that the incidence of malaria in Colaba (the adjacent part of Bombay) has been diminished, although malaria has been severe in other parts of Bombay.

During the congress many pleasant excursions to places [illegible]rest in Bombay were arranged and much private [illegible]ity was shown to members of the congress.

## "MARIAHUANA."

UNDER this name, which is peculiar to Mexico and is probably of Indian origin, it is not easy to recognise our old friend *Cannabis indica*. But it is the official name for it in Mexico, and as such it figures very largely among the contraband drugs which are seized yearly by the Mexican customs authorities. The growing, importation, and sale of *Cannabis sativa*, as it should be called, are strictly forbidden in Mexico, where it is classed amongst the "drogas heroicas" with morphine, heroin, and cocaine. It grows wild in parts of Mexico, and the leaves are rolled into cigarettes. The report of the Mexican Ministry of Health shows that large quantities are confiscated in the year, but this is probably in the bulky form of dried leaves not prepared in any way. The smuggling seems to be chiefly on the United States border.

## MANCHESTER ROYAL INFIRMARY.

AT the annual meeting of the trustees of the Manchester Royal Infirmary held on Feb. 12th, the board expressed regret at the resignation of Sir William Cobbett, who had been chairman for 21 years. It was greatly owing to his energy that the money was got together for the building of the infirmary. A life governor stated that at Aberdeen Royal Infirmary the ordinary income exceeded the expenditure, and that last year about £100,000 was collected from working men alone for the Glasgow infirmaries. In Manchester the comparatively meagre sum of £10,000 had been contributed. He appealed for an organiser to foster interest in the city's hospital and for the appointment to the board of a member to represent the workmen outside. Pointing out that there were committees of workmen in connexion with the Hospital Saturday and Sunday Funds, he said that in Scotland organisers went to the works to speak to the workmen. The workpeople of Manchester, he was sure, would be agreeable to a regular weekly deduction for the hospitals, and if the workers were persuaded to do better, then the employers would follow suit.

## THE FOOD OF THE COUNTRY.

THE centenary of Brillat-Savarin, marked by the issue of a sumptuous translation of his great work,[1] has also been acclaimed at memorial feasts in Paris and London. When Brillat-Savarin, having caught a cold at the age of 80, died in Paris this month 100 years ago he believed that he had put an end, once and for all, to the foolish confusion which existed in men's minds between gluttony and gourmandism; between eating grossly, like a beast, and eating choicely, like a man. Within his own country, perhaps, his faith was justified, and the wise and witty gospel of his "Physiologie du Goût" was not preached in vain. France is still the land where gourmands are happiest. Yet even in France societies have been formed (ominous phrase!) in recent years for the encouragement of good cooking in general, and in particular for the preservation of local or provincial recipes of outstanding excellence; and too often it has proved necessary not so much to preserve what exists, as to revive what had been forgotten. The "wine of the country" is often sentimentally extolled by travellers, and is sometimes extremely nasty; the "food of the country" apt to be so excellent gets no such notice and its disappearance goes unnoticed. In England the untranslatable designations in restaurants of all but the simplest dishes, and the gradual disappearance of "tariff" and "bill of fare" from the language, in favour of "carte" and "menu," show that we are prepared in this country to support the very thing which the French gourmets regret, and in England many of our national dishes have disappeared. We are gastronomically denationalised save in matters of daily routine; we imitate our continental neighbours, and our imitations are not convincing.

---

A VARIETY ARTISTS' BED.—Last week, at the Royal Northern Hospital, a bed was dedicated to the Variety Artists' Federation in recognition of the services rendered by it to the hospital. Sir Harry Lauder unveiled a tablet which has been placed over the bed.

A HOSPITAL BAZAAR.—The Duke of York attended the "Barbary Coast Bazaar" held recently at Sunderland in aid of the fund that is being raised for the new Monkwearmouth and Southwick Hospital. It is now announced that the bazaar, which was visited by more than 60,000 people, has produced a profit of £9511. This hospital and Sunderland Royal Infirmary have raised between them £110,000 during the last 12 months.

# An Address
ON THE
# MALARIA TREATMENT OF GENERAL PARALYSIS OF THE INSANE

*Delivered at the Liverpool Medical Institution on Feb 4th, 1926,*

BY WARRINGTON YORKE, M.D LIVERP.,
PROFESSOR OF PARASITOLOGY, UNIVERSITY OF LIVERPOOL.

ATTEMPTS to discover a successful treatment of general paralysis of the insane have taken two main lines, the one, which we might call specific therapy, is naturally of comparatively recent date and commenced with the recognition of the true nature of the disease, whilst the other—non-specific therapy—dates back to very early times.

Until recently all efforts at specific therapy have proved futile. Intrathecal, subdural, intraventricular, and intracisternal injections of salvarsan or of its various modifications, or of salvarsanised serum, were found to be just as useless as the earlier methods of inunction or intramuscular injections of mercury and of intravenous injections of salvarsan In 1910 information regarding the mode of preparation and chemical constitution of a new arsenical—tryparsamide—was published by Jacobs and Heidelberg, of the Rockefeller Institute; and about the same time Pearce and Brown gave an account of its biological behaviour and therapeutic action on animals experimentally infected with trypanosomes. During the last six years this drug has been used extensively in the treatment of human trypanosomiasis—a disease which in many respects is closely allied to syphilis—with very remarkable results. In a recent review (Yorke, 1925) the published results have been collected and subjected to critical analysis, and it is now definitely established that not only does tryparsamide produce immediate peripheral sterilisation of the blood both in early and in very advanced cases, but that it exerts a profound influence on the meningeal reactions. In short, this drug possesses the unique power of benefiting, and apparently curing, a not insignificant proportion of cases in the second stage of sleeping sickness with altered cerebro-spinal fluid. Of recent years the drug has been employed, particularly in America, with considerable success in the treatment of general paralysis, and much is to be hoped from experimental work along these lines

## NON SPECIFIC TREATMENT.

It is, however, with the second line of attack—the non-specific therapy—that we are concerned on the present occasion Gerstmann (1925), in his excellent monograph on this subject, shows that the historical development of the non-specific treatment of general paralysis dates back to very early times, he records that Hippocrates and Galen knew that febrile disturbances might exert a curative effect on the course of psychosis, that Boerhaave and Sydenham were familiar with the curative influence of intercurrent fevers on mental disorders, and that Reuss in 1786 had observed the cure of mania through small pox. The literature of the middle and latter portions of the nineteenth century contains numerous references to the improvement produced in psychoses by intercurrent febrile disturbances, such as typhoid, typhus, intermittent fever, cholera, variola, erysipelas, scarlatina, pneumonia, chronic suppuration, and abscesses.

These observations led gradually to the adoption of various procedures devised with the object of producing suppuration or fever; these consisted essentially of the injection of various substances which can be grouped into three classes: (1) substances not derived from micro-organisms—i e, sodium nucleinate, phlogetan, albumose, peptone, and milk, (2) substances derived from micro-organisms—i e, tuberculin, polyvalent typhoid, and staphylococcus vaccines; and (3) the living micro-organisms of infectious diseases. According to Wagner-Jauregg, who has devoted many years to the study of the subject, the weakest action is obtained from the substances of non bacterial origin, a stronger action from those of bacterial origin, and the best action from the actual infective processes themselves. It was considerations of this nature which led Wagner-Jauregg in 1917 to attempt the treatment of general paralysis with tertian malaria.

### *Technique.*

Of the three species of malaria parasites, undoubtedly the one to be used is that of simple tertian malaria (*Plasmodium vivax*); malignant tertian malaria is extremely dangerous; in quartan malaria the febrile attacks occur only every fourth day, and it has been found for this and other reasons less satisfactory than *P vivax*. Malaria infection can be induced in either of two ways: (1) by the inoculation of infective blood from a patient suffering from malaria, and (2) by allowing infective anopheline mosquitoes to bite. In practice the most usual method is the former The blood—1 or 2 c.cm.—can be injected either subcutaneously, intramuscularly, or intravenously, very occasionally subcutaneous or intramuscular inoculation for some unknown reason fails to infect, but in our experience intravenous injection is practically invariably successful. The arm-to-arm method of infection presents no difficulty in asylums and other institutions where large numbers of patients are available for treatment, but in the treatment of isolated cases it presents the practical difficulty that if the infected blood has to be obtained from a distance the malaria parasites which it contains may be dead before they are inoculated. Various procedures have been advocated for keeping malarial blood alive, but the most satisfactory is undoubtedly maintaining the blood to which a few drops of 50 per cent. glucose solution is added at low temperature, preferably on ice. If this is done the blood will remain infective for many hours.

After an incubation period varying from 8–22 days (usually 8–15 days) the patient develops fever and the malarial attacks commence. The febrile disturbances usually last about 8–12 hours and occur typically every other day; this is the typical simple tertian fever Not infrequently, however, there may be a daily rise of temperature, the curve being of the quotidian type; or the fever may commence as tertian and then become quotidian or vice versa. Whether the fever is tertian or quotidian has nothing to do with the strain of parasites used, but is dependent upon the reaction of the host.

Experience has shown that it is desirable to allow the patient to have from 8–12 febrile paroxysms Reaching a decision when to stop the malaria is the chief cause of anxiety to the practitioner; if the febrile attacks be stopped prematurely no good may result, and if they be allowed to continue too long the patient's life may be sacrificed. As a general rule, there should be no medicinal interference with the patient during the malaria. If the fever reaches alarmingly high levels (105° F or more) it can be controlled by sponging; it is of the utmost importance to bear in mind that it is impossible to control the fever by the administration of small doses of quinine; the fever can at once be stopped by quinine, but it cannot be controlled and kept within moderate bounds by the use of fractional doses of this drug. Even such a small dose as 5 gr may stop the fever, and this can only be regarded as a disastrous procedure, because not only is the treatment stopped prematurely and the chance of benefiting the nervous disease thereby nullified, but, as a rule, the patient cannot again be infected for some considerable period.

When the patient has had the requisite number of malarial paroxysms, or it has been determined for other reasons to stop the malaria, 30 gr of quinine in solution should be given daily for three consecutive days; no further treatment is necessary and in the vast majority of cases the malaria is definitely cured; very rarely after an interval of one or more months a malarial relapse occurs, but this can be dealt with in a similar manner by the three days' course of quinine.

### *Indications and Results*

In considering the suitability of a case to undergo the malaria treatment, attention must naturally be paid to the somatic condition of the patient and to the age, stage, and form of the disease As Gerstmann points out, the chief concomitant of syphilis of the central nervous system is disease of the circulatory system, particularly of the aorta. Frisch (1923) has shown that of 115 cases of nervous syphilis 30 per cent. had aortic disease and that this was present in 29 per cent of paralytics; Löwenberg (1924) found post-mortem changes in the aorta of 113 (33 per cent.) of 341 cases of general paralysis. Notwithstanding the frequency of aortitis in general paralysis, the condition is, however, as a rule not severe and rarely a cause of death; only nine of Löwenberg's 113 cases in which the aorta was affected exhibited aneurysms and only one died of the condition. The presence of aortitis is consequently not a contra-indication to the malaria treatment; but severe aortitis with aneurysmal dilatation and myocardial degeneration are undoubtedly contra-indications, as is also gross obesity, and the treatment in such cases may lead to sudden death. Such considerations in a disease like general paralysis in which the prognosis is otherwise hopeless do not appear to have much importance, and one can, I think, act on the general rule that all cases should be treated except those who are very advanced and in a feeble state of nutrition and bodily physique, and those in whom there is serious organic lesion with pronounced disturbance of function.

By far the most extensive records of the malaria treatment of general paralysis hitherto published are those from the Vienna Clinic, where the work was inaugurated as long ago as 1917 by Prof. Wagner-Jauregg. Gerstmann in his recent monograph gives the results in so far as they concern patients treated between 1917 and 1922. He observes that over 1000 cases of general paralysis have up to the end of 1924 been treated by this method, but that in dealing with a disease like general paralysis it is preferable to limit one's statistics to the 400 patients treated previous to 1923, so that only cases who had been observed for at least two years after treatment should be considered. In Table I. I have summarised the information given by Gerstmann regarding the results obtained in these patients.

TABLE I.—*Showing Results of Malaria Treatment in 400 General Paralytics at Vienna Compiled from Information Supplied by Gerstmann (1925).*

| Date treated. | Total cases. | Complete remission. | Partial remission. | Slight change, no change, or dead. |
|---|---|---|---|---|
| 1917 .. .. | 9 | 4 | 2 | 3 |
| 1919–1920 .. | 25 | 8 | 3 | 14 |
| 1920–1921 .. | 116 | 38 | 14 | 64 |
| 1921–1922 .. | 250 | 83 | 40 | 127 |
| Total .. | 400 | 133 (33 %) | 59 (15 %) | 208 (52 %) |

It thus appears that one-third of the 400 Vienna cases which have been under observation for periods varying from two to seven and a half years after treatment have remained in a state of complete clinical remission.

The data available from this country is much less complete. The Whittingham Mental Hospital was the first institution in England to examine the treatment, and at the request of Dr. R. M. Clark, the medical superintendent, a number of his patients were infected with malaria at the Liverpool School of Tropical Medicine in July, 1922, and from these the strain was carried on at the asylum by direct inoculation from one patient to another. Shortly afterwards patients were infected at the Winwick, Rainhill, Belfast, and Sheffield mental hospitals. I have been able to accumulate the broad results obtained at these institutions, partly from papers published by the medical officers in charge of the patients and partly from information kindly supplied by the courtesy of the medical superintendents; this information is summarised in Table II.

These results, although less valuable than those from the Vienna Clinic, are nevertheless very encouraging. They naturally do not carry the weight of the Vienna series, as the treatment is of much more recent date, and consequently the post-treatment observation period is of necessity much shorter. However, the fact that of 299 patients 70 (23·4 per [illegible] vered sufficiently to be discharged from the asylums is striking testimony to the value of the treatment, when it is borne in mind that all the cases were asylum patients and that from none of these institutions had a case of general paralysis previously been discharged.

TABLE II.—*Showing Results of Malaria Treatment of General Paralytics in Five British Mental Hospitals.*

| Mental hospital. | Total cases treated. | Dis-charged. | Greatly improved. | Slight improvement or no change. | Dead. |
|---|---|---|---|---|---|
| Winwick* .. | 53 | 7 (13·2 %) | 9 | 22 | 15 |
| Belfast† .. .. | 72 | 24 (33·3 %) | 6 | 25 | 17 |
| Rainhill† .. | 74 | 14 (19 %) | 8 | 26 | 26 |
| Sheffield† .. | 53 | 18 (34 %) | 21 S.I. | 7 N.C. | 7 |
| Whittingham‡ | 47 | 7 (15 %) | — | 33 S.I. or N.C. | 7 |
| Total .. | 299 | 70 (23·4 %) | — | | — |

* Data published by Davidson (1925).
† Information kindly supplied by the medical superintendents—viz., Dr. Graham, Dr. Reeve, and Dr. Vincent.
‡ Data published by Grant and Silverston (1924).
S.I. = Some improvement. N.C. = No change.

The larger proportion of apparent cures recorded by Gerstmann is doubtless due to the fact that the Vienna patients were pre-asylum cases and consequently less advanced at the time of treatment; this is borne out by the results obtained in Liverpool during the last three and a half years among pre-asylum cases where apparently complete remissions have been obtained in over a third of the patients. Analysis of the information supplied by Gerstmann indicates that remarkably few of those who exhibited complete remissions relapsed, and this agrees with our experience in the treatment of pre-asylum cases and also with the fact that very few of the patients discharged from the British asylums have so far had to be readmitted.

### *Can the Result of Treatment be Forecast?*

The question whether it is possible in any particular patient to forecast the result of treatment is obviously one of great practical importance. Any of the following results may be obtained: (1) a remission so complete and lasting that the patient is apparently cured; (2) partial mental remission accompanied by so great a somatic improvement that the patient is physically apparently normal; (3) partial mental and physical improvement; (4) no change mentally, but some physical improvement; (5) the condition remains in statu quo; (6) death.

In a disease like general paralysis where the mental changes are pronounced, the only result which can be regarded as really satisfactory is that in which the remission is so complete that the patient regains his former mental and physical powers and is enabled to return to his occupation and once more become a reasonable and useful member of society. As the statistics which I have quoted show, this most desirable result is obtained in from 23 to 33 per cent. of cases. It is upon these results that the treatment is justifiable and, pending the discovery of something better, to be advocated at the present time.

Unfortunately, in many cases an intermediate result is obtained; the patient is neither killed nor cured, nor is the condition left unchanged to proceed on its natural course to a fatal termination. In these the course of the disease appears to be arrested, the patients improve physically to a truly remarkable extent, they become cleanly in their habits—as one medical officer of an asylum put it, "instead of having to change the bed linen eight or ten times a day once suffices." They regain to some extent their mentality, but this is all; they cannot return to work and are no longer useful members of society. Regarded from the purely utilitarian point of view this can only be described as a disastrous result, and from the same point of view the treatment cannot be justified. If, however, we regard the arresting of pathological processes and the prolongation of human life as one of the objects of medical science, then we are compelled to conclude that even results of this category justify the treatment.

Beyond the obvious generalisation that the earlier the patient comes under treatment, the more likely is the result to be entirely satisfactory, it seems at present impossible to forecast the result in any particular case. Gerstmann, writing on the 1000 cases treated at the Vienna Clinic, states that "good remissions are to be expected in the so-called early cases, in maniacal cases, in cases of simple dementia, in cases characterised by seizures, and in tabetic cases; whilst poorer results are obtained in galloping cases, in advanced cases, in infantile-juvenile cases, and in senile cases."

It should be noted that the complete remission may be sudden and dramatic and may occur quite early, actually during the malarial attacks, or it may be slow and progressive and the full result may not be obtained until the lapse of several months after the treatment.

Finally, it cannot be ignored that even in the earliest and strongest patients the treatment is attended with a certain risk to life. This, however, is very slight in the average early case, provided the person who is in charge has the requisite knowledge of malaria, but in the hands of the inexperienced the malaria treatment is undoubtedly a two-edged sword; on the one hand, the physician may become unduly alarmed at the severity of the malarial manifestations and attempt prematurely to modify or even cut short the attacks by the administration of small doses of quinine, and thereby not only nullify the effects of the treatment but prevent its repetition for a considerable period, or, on the other hand, he may so delay interfering that the patient is killed by the malaria.

### *Disappearance of Pathological Reactions.*

It is now definitely established that the pathological reactions of the serum and spinal fluid disappear completely in certain cases after malaria treatment. Gerstmann has collected very considerable data on this subject from the Vienna Clinic. As a rule, it is the inflammatory reactions—lymphocytosis and excess of globulin—which tend to subside first; whereas the non-inflammatory changes—Wassermann and Goldsol reactions—disappear much more slowly. Gerstmann observes, however, that the changes in these reactions appear at first to be quite independent of the clinical manifestations. Cases are met with in which there is complete clinical remission with little or no alteration of the serum and spinal fluid reactions, and, on the contrary, in other cases there may be no clinical change but very great improvement in the serum and spinal reactions. Apparently, from the point of view of prognosis much more importance is to be attached to the clinical manifestations than to alterations in the fluid reactions. Cases in which there is complete clinical remission may exhibit unchanged fluid reactions for prolonged periods, or these may slowly tend to become normal; whereas in those who exhibit no clinical remission, but markedly improved fluid reactions, these, as a rule, generally revert sooner or later to their previous pathological condition.

There is now available a considerable mass of information regarding the condition of the brain in general paralytics, who have died during, or at various intervals after, malaria treatment. Lewis, Hubbard, and Dyar (1924) carried out an exhaustive examination of the brains of four cases who had died after malaria treatment and failed to find spirochætes in two of them, and only comparatively few were discovered in the others; they remark upon the greatly diminished perivascular infiltration; Jossman and Steenaerts (1924) were unable to find spirochætes in the brains of eight similar cases. Sträussler and Koskinas (1923) reported upon the brains of three general paralytics, who had shown complete remission as the result of malaria treatment and had later died from intercurrent disease; the pathological changes discovered were so slight that the authors state it would have been almost impossible, without the clinical history, to have made a diagnosis of general paralysis. Gerstmann gives information regarding the case of a general paralytic who died as the result of an abdominal operation two and a half years after malaria treatment, and who in the interval had been perfectly well and able to work; surprisingly few pathological changes were found; the inflammatory changes were particularly scanty and consisted of sparse lymphocytes and exceptional plasma cells on occasional precapillary vessels; recent glia proliferation was completely absent, and the meninges showed only here and there slight lymphocyte infiltrations. Somewhat similar cases have recently been recorded by Löwenberg and by Steiner.

It is interesting to compare these observations with those of Sträussler and Koskinas on four patients who died during the attacks of malaria, and on 24 who died at the end of the malaria or shortly afterwards. In three of the four who died during the malaria attacks, the inflammatory and proliferative changes were present in a most striking degree and represented an exaggeration of what is usually found in general paralysis; in 15 of the 24 who died immediately, or shortly, after completion of the malaria treatment, the ordinary appearances typical of general paralysis were seen, but in the remaining nine there was evidence of a definite retrogression of the pathological processes. As the result of these observations Sträussler and Koskinas believe that the first effect of malaria infection on general paralysis is an acute increase in the infiltration and proliferative processes in the vessels and glia, and that this exacerbation of the inflammatory reactions is a forerunner of the following subsidence and is an indication of the tissue warfare against the syphilitic virus. In this connexion it should be noted that during the malarial attacks there is often a transient increase in the clinical manifestations of the disease and in the inflammatory changes in the cerebro-spinal fluid.

## NEW OBSERVATIONS ON MALARIA.

I should like now to refer briefly to the other side of this subject. When Dr. Clarke, of Whittingham, first asked us to infect for him a number of cases of general paralysis, I had very little belief that it would do any good, but it at once occurred to me that as the alienists wished to call in the aid of a tropical disease to assist in the treatment of a mental disease, it was only right and proper that those whose interest lay in exotic diseases should seize the opportunity, which the occasion presented, of making a number of much desired observations on malaria. During the past three and a half years Dr. Macfie and I have devoted considerable time to this aspect of the subject and a number of very interesting facts—some of them, I think, of fundamental importance—have come to light.

### *Cure of Induced Malaria.*

The first question which at once aroused the interest of those concerned with tropical diseases was the ease with which the induced malaria could be cured in the general paralytics. Wagner-Jauregg drew attention to this fact in his original paper; he pointed out that two or three weeks' treatment with moderate doses of quinine was apparently sufficient to cure the malaria and that relapses were exceedingly rare. Wagner-Jauregg believed this to be due to the fact that passage of the malaria parasites from patient to patient, instead of from mosquito to patient, as always happens in Nature, had in some manner modified the virulence of the parasite and rendered it more susceptible to quinine.

In order to obtain information on this point and on a number of others, it soon became obvious that we should have to infect general paralytics by Nature's method—i.e., by the bite of infective mosquitoes—instead of by direct inoculation of infected blood from another patient. In all, we have infected about 50 general paralytics with malaria by the bite of infective mosquitoes, and the observations on malaria which I am about to summarise were made on these cases which are, of course, strictly comparable with the infections which occur in Nature.

Even up to the present time a number of authors, more particularly the French, still adhere to the view that there is only a single species of malaria parasite found in man; evidence was, however, adduced during this work which in our opinion renders the unicity hypothesis of the malaria parasites of man untenable.

The incubation period of simple tertian malaria in man was shown to vary considerably, the first rise of temperature occurring in from 9 to 22 days after the bites of infective mosquitoes and parasites appeared in the peripheral blood for the first time in from 13 to 21 days. Another interesting observation was that although the first parasites to appear in the peripheral blood were almost invariably trophozoites, in all cases gametocytes (forms which are capable of infecting mosquitoes) made their appearance two or three days later.

### *Action of Quinine.*

Of much greater practical interest, however, are the observations which we have been able to make regarding the action of quinine in the cases of mosquito-induced malaria. Our inquiry followed two directions, firstly, to ascertain whether quinine given prophylactically prevented the development of malaria; and secondly, to examine the therapeutic action of the drug and determine whether the mosquito-induced malaria was as easily cured by a short course of the drug as are the inoculated cases, or whether they subsequently relapsed with the same regularity as did the war cases and the majority of cases in tropical practice.

Numerous observations showed that quinine has no true prophylactic action in malaria, the administration of such doses as 10 gr. in solution daily for five days before, the day of, and for eight days after the bite of infective mosquitoes failed to prevent the development of malaria, the patients developing fever and showing parasites in the blood in about the usual time; similar results were obtained in cases where 30 gr. of the drug in solution were given on the day of feeding infective mosquitoes and on each of the two following days. These experiments showed conclusively that quinine has no action on the sporozoites (infective germs) injected by the mosquito, and consequently that the drug has no true prophylactive action. When, however, the daily dose of quinine is continued for ten or more days after the meal of infective mosquitoes, the infection does not develop.

Therapeutic observations showed that the mosquito-induced malaria resembled the inoculated malaria in being remarkably susceptible to treatment, a short course of quinine, gr. 30 for three consecutive days being sufficient definitely to cure the malaria in 43 per cent. of cases; in the remaining 57 per cent. a relapse occurred for the most part between four and 11 months later, but in the great majority of the relapses the parasites and fever either disappeared spontaneously or as the result of only one more three-day course of quinine. The broad fact thus emerges that the administration of moderate doses of quinine for only a few days has in these cases sufficed either definitely to cure the malaria, or at least to control it for a period of 15 to 21 months.

These results are in striking contrast to those obtained in the treatment of malaria during the war and in ordinary tropical practice. Observations on over 2000 cases of malaria at the Liverpool School of Tropical Medicine during the war showed that, whatever the treatment administered, the vast majority relapsed within a month of its cessation. The difference cannot be explained on the obvious hypothesis that the cases of induced malaria were syphilitics, [illegible] of them were non-syphilitic cases of dementia [illegible] encephalitis, and disseminated sclerosis, and [illegible]onded to quinine treatment in the same way.

### *Factors Influencing Relapses.*

The question now arises what is it that determines whether, or when, a relapse will occur? An exhaustive examination of the factors which might influence the occurrence of relapses showed clearly: (1) That provided a certain minimal dose (20–30 gr.) of quinine was given for two or three days, the amount of the drug administered exercises no influence. (2) That the period of the year when cases are infected or treated is immaterial. (3) That the particular strain of *Plasmodium vivax* with which the patient is infected has likewise no effect. (4) That the factor which does govern the relapse question is the patient himself.

In records relating to therapy, so much attention is usually paid to questions of dosage and methods of administration of drugs, and to speculations regarding differences in virulence of strains of parasites that this all-important factor—viz., the reaction of the patient—is frequently overlooked, and failure to take it into account gives rise to incorrect interpretation and deductions. Now in what respect did these experimental cases, which were so readily controlled by quinine, differ from the war cases and those one usually encounters in tropical practice? The former were at the time of treatment all primary infections, whereas the latter were old-standing relapse cases; and this, I believe, is the true explanation of the difference in their reaction to therapy.

### *Mechanism of Cure in Malaria.*

This brings us to a consideration of the mechanism whereby a cure is obtained in malaria. As a result of much work on this subject Macfie and I advanced the following hypothesis. Quinine given to a patient whose blood contains numerous malaria parasites invariably destroys directly, or more probably indirectly, large numbers, but not all, of the parasites, thus setting free a considerable quantity of soluble antigen. The antigen provokes by stimulation of the host's tissues the formation of immune body. The immune body, if present in sufficient amount, destroys the remaining parasites, thus resulting in sterilisation of the infection and in cure of the patient.

As will be seen, this hypothesis embodies two postulates; firstly, that no form of quinine therapy ever destroys all the malaria parasites in the human body; and secondly, that the tissues of the host are able, in response to antigen stimulus, to produce a sufficient quantity of immune body. We have been able to accumulate a considerable mass of evidence indicating the correctness of these postulates; this has been considered elsewhere (Yorke and Macfie, 1924, and Yorke, 1925), and I need not deal with it here.

Of late years evidence has been forthcoming that a number of drugs, which are of the utmost value in the treatment of specific diseases, have themselves little or no action on the parasites which produce the diseases. For example, atoxyl is known to be of the utmost use in the treatment of sleeping sickness and quickly causes the parasites to disappear from the blood of an infected man or animal, yet, if mixed with the parasites in a test-tube, the drug has no action on them; if, however, atoxyl is treated with fresh extract of liver, it speedily becomes parasiticidal (Levaditi). Again, it has long been known that fresh human serum will cure mice infected with sleeping sickness, whereas it has no action on the parasites in the test-tube; the explanation is that the serum reacts with the reticulo-endothelial system of the mouse and the product is parasiticidal; Rosenthal and Freund have shown that if the reticulo-endothelial system of the mouse be put out of action by splenectomy and other measures, then the injection of human serum is useless. Finally, if quinine be incubated for some hours with malarial parasites the parasites are not killed, because the mixture when injected into a patient produces infection.

Although, then, the experimental proof is still lacking, it seems highly probable that quinine, when introduced into the human body, is in some way changed into an active substance, and that certain body-cells play an important part in causing the disappearance of malaria parasites from the blood which follows quinine administration. This process does not, however, result in sterilisation of the infection; most of the parasites are destroyed, but some remain and they exist in the human body for long periods without increasing sufficiently in number to appear in the peripheral blood. They are held in check by immune body and a state of balance or tolerance results. This state of balance ends in one of two ways: either the infection dies out and a cure is obtained, or it re-establishes itself and a relapse occurs; which alternative results is dependent entirely on the host and any factor which tends to lessen the capacity of the host to form immune-body assists in the production of a relapse. What these factors are we can only speculate, but there may well be deficient nutrition, ill-health due to extraneous causes, exhaustion and strain, repeated infection, and lastly, and possibly not least, over-dosing with quinine.

### *Evils of Over-Administration of Quinine.*

Having regard to the fact that the action of many drugs is indirect—i.e., they must react with the body-cells before they are capable of destroying the parasites—it is at once apparent that there may be very definite ill-results from the over-administration of the drug. Experience in the war showed clearly the impossibility of sterilising a malarial infection merely by raising the dose of the drug; such enormous daily doses as 90 or 120 gr.—doses which border on the toxic—were futile, as also were such courses as 45 gr. daily for two months and 30 gr. daily for four months. Within a week or two of the cessation of treatment a relapse occurred, and frequently, as a matter of fact, even whilst the patient was taking these large doses of quinine. Furthermore, there is evidence that no good results from the administration of quinine when the blood is negative; and I have already referred to the experimental work conducted by Macfie and myself which showed that quinine has no true prophylactic action in that even such large doses as 30 gr. for three days fail to destroy the sporozoites which the mosquito injects.

Turning now from this brief summary of certain of the limitations of quinine, let us consider for a moment the manner in which excessive quininisation may be detrimental. Apart altogether from the fact that prolonged administration, or very large doses, of quinine upset the digestion and nervous system of many persons and thereby lessen the general resistance, there is possibly a much more directly pernicious effect of such a procedure. Let me refer once more to the fact that human serum cures mice infected with sleeping sickness and recall that this is due to the formation of a parasiticidal substance produced by the interaction of the serum and the reticulo-endothelium of the mouse. Now it has been shown by Rosenthal and Freund (1923 and 1924) that repeated injection of human serum into mice inhibits the protective action of a dose of the serum administered later, after the mouse has been infected with trypanosomes; this has been proved to be the result of an exhaustion phenomenon, the repeated doses of serum wearing down the reticulo-endothelial system, so that it finally ceases to react with the serum to produce the parasiticidal substance.

Is it not likewise possible that in the treatment of malaria also there may be a danger from excessive doses, or from the prolonged administration, of quinine, of exhausting the body-cells which react with the drug to form the parasiticidal substance; and may not excessive quininisation be one of the factors which rendered the war cases and the majority of cases of malaria one encounters in private practice so difficult to cure?

### CONCLUSION.

In conclusion, may I express the hope that I have succeeded in showing that this interesting reaction of one disease upon another has thus a two-fold effect in that "it blesseth him that gives and him that takes." A not inconsiderable proportion of the paretics are restored to health, and those who suffer from malaria will doubtless in due course benefit from the advance of knowledge which the remarkable influence of this infection on the nervous disease alone has made possible.

# A NOTE ON FIFTEEN CASES OF OPERABLE CARCINOMA OF THE BREAST TREATED BY RADIUM AND X RAYS.*

BY J. H. DOUGLAS WEBSTER, M.D., M.R.C.P. EDIN.,
PHYSICIAN IN CHARGE OF THE DEPARTMENT OF RADIOLOGY;
J. P. THIERENS, B.Sc., M.B., CH.B. LIVERP., D.M.R. & E. CAMB.,
ASSISTANT RADIOLOGIST;
AND
F. G. NICHOLAS, M.B., B.S. LOND., M.R.C.S. ENG.,
RADIUM OFFICER.

*(From the Department of Radiology, Middlesex Hospital, London.)*

IT is not suggested in this paper that radiation should be preferred to operation in operable cases of breast cancer; radiation treatment is still too much in the experimental stage in its application to malignant disease, and its results are still too little known for this attitude to be adopted. At the same time radiation, which has sometimes led to the complete disappearance of inoperable growths and recurrences, should give very good results in operable cases, and radiologists therefore ought to study and discuss the problems of the treatment of operable breast cancer, for they never know when an operable case may be referred to them for some special reason.

A vast amount of attention, time, and money is devoted in every radiotherapeutical clinic to the treatment of inoperable primary or recurrent malignant disease, for which for the most part palliation is the only reasonable aim; but when an operable case is referred there is as yet no unanimity as to the best method of dealing with such a case, nor is there accurate knowledge as to the results of the different X ray and radium techniques which may be employed. And yet here it is not the degree of palliation, but *cure* (as far as the word can be used in speaking of malignant disease) which hangs in the balance for the patient. The responsibility is therefore great on the radiologist in dealing with such cases, for clinical cure should result in a high proportion—in nearly every case indeed, unless there is already distant metastasis, or some as yet unknown biochemical factor reducing the natural immunity, as there appears to be in patients who develop cancer during pregnancy.

In the following series every patient either refused operation, or else age, chronic bronchitis, heart disease, or glycosuria made operation inadvisable.

---

* Read before the First International Congress of Radiology, London, 1925.

The interim results suggest that such patients should be more freely offered the alternative of radiation treatment than they are at present; at least they should not be told that there is no alternative to operation.

### *X Ray Cases (8).*

CASE 1.—Mrs. S., aged 82. This patient had been successfully brought through a double apical pneumonia two years previously by her medical man, Dr. F. W. Rix. A mass appeared in her right breast, in the upper and outer quadrant, and she was seen by a surgeon, who advised that operation was the only course to be considered. The patient's son, however, was a medical man, and he and Dr. Rix, considering the patient's age, her history of pneumonia and chronic bronchitis, and her bad heart, consulted Sir William Willcox and the late Sir James Galloway, who both advised strongly against operation. The patient was brought to one of us (J. H. D. W.), and deep X ray treatment was given (May, 1922). The mass was hard, 6 by 8 cm. in size, adherent to the pectoral muscle. On July 11th the mass could hardly be felt. On Oct. 3rd the small soft residue was treated again. The general condition was good. In December she suddenly fell ill with broncho-pneumonia in both bases, and died after only a few days' illness. The opinion of those in medical attendance was that this terminal illness was in no way connected with the previous breast condition.

CASE 2.—Mrs. S. S., aged 55. This patient came into the Middlesex Hospital under Mr. Sampson Handley. There was a stony hard mass in the axillary tail on the left side 10 by 7 cm. in size. Treatment was given in February, 1925, and in April, by which time the mass was much smaller, and again in May. On June 24th Mr. Handley saw the patient and noted that the mass had apparently disappeared. The skin is still puckered in and adherent at the site where the mass was. The patient feels and looks in much better health than she was when first seen in February. This is a new case, but the immediate result has been very good.

CASE 3.—J. S., aged 75. This patient came with a four months' history to Mr. Handley. She refused operation, and Mr. Handley advised X rays. She had an "atrophic scirrhus, deep pucker of skin, slight underlying induration; no glands" (from Mr. Handley's note, Feb. 19th, 1919) in the lower inner quadrant of the left breast. She had attended irregularly for some time before this for low voltage X ray treatment, then had no X rays for nearly four years. In December, 1923, the residue was slightly adherent to deeper structures, and she had more X ray treatment. In November, 1924, the left axillary glands were enlarged; after treatment they were no longer palpable in January. Seen again at intervals, she remains in a satisfactory local and general state, with no more treatment. *(See notes at end.)*

CASE 4.—E. E., aged 77. She came to hospital under Mr. Handley giving a three years' history. She refused operation. She had a hard mass in the left breast adherent both to skin and muscle, with peau d'orange appearance of the lower breast; there was a hard gland in the left axilla. She had high voltage treatments in July and September, 1924, and January, 1925. The residue appears to be quiescent.

CASE 5.—Mrs. G., aged 78. This patient refused operation. The left nipple was drawn up compared with the opposite side. There was a hard localised mass 6 by 6 cm. in size, slightly adherent to the skin; no palpable glands. She was treated in June, July, September, and October, 1924, by *cross-fire, high voltage*. The residue now is hardly palpable, it is about 2 by 0·25 cm. in size. There has been no treatment since October, 1924, the patient reporting every three months for observation.

CASE 6.—Mrs. D., aged 71. She reported with a large hard mass 9 by 8 cm. in size in the right breast, the skin was adherent, and nipple deviated; no glands were palpable. Owing to age and chronic bronchitis, operation was inadvisable. After two deep X ray treatments in September and October, 1922, the mass was reduced to the size of 6 by 5 cm. In December, her daughter wrote to say she was in bed with a "chill." She never reported again, in spite of repeated letters. She died nearly two years and a half after last being seen, in February, 1925; the breast had become ulcerated. Treatment in this case was incomplete, the patient was debilitated, and always objected to anything being done for her; this result therefore was [illegible]usive.

[illegible] 7, Mrs. B., aged 77, and CASE 8, A. L., aged 71, [illegible] Both are improving.

Cases 9 and 10 have been treated by combined radium insertion and X ray.

CASE 9.—B. R., aged 64, had a scirrhus in the right axilla and upper outer quadrant. She refused operation. She had a preliminary X ray treatment on June 17th, 1921. Ten days after Mr. Handley inserted radium, 250 mg. (radium bromide), in five tubes for 13 hours. "The skin was involved, there was considerable infiltration of the breast, and two subcutaneous nodules." A year later, in June, 1922, "the growth was quiescent." In September there were four skin nodules, and more X ray treatment was given. Seen in March, the skin nodules had gone. Twice since then small skin nodules have appeared, and have been no longer palpable after X ray treatment. Her general condition remains good, and there are no signs of any extension beyond the right axillary fold. For four years the disease has been kept well under control.

CASE 10.—R. P., aged 48. Seen by Mr. Handley in March, 1924. There was a "lump causing deviation and retraction of the left nipple, and a hard enlarged gland in the left axilla. Diagnosis "atrophic carcinoma." Mr. G. Gordon-Taylor buried radium round the growth by the "*encirclement method*" Mr. Handley has described, five 50 mg. Br, for 18 hours, on May 17th, 1924. The axilla was treated by deep X rays in June, and a small gland appearing in the opposite axilla also had X ray treatment; the left breast and supraclavicular and left scapular areas had medium voltage X ray applications in July and August. On Sept. 30th Mr. Gordon-Taylor again buried radium round the growth and by the axilla. On Nov. 10th she was seen by Mr. Gordon-Taylor, and was "greatly improved; there was no sign of recurrence." In the last two months, however, she has developed a radium dermatitis, and is having treatment for that in the hospital at present. There is practically no sign of growth now. In both of these cases the combined use of radium insertion and X ray has been very effective. *(See notes at end.)*

The five concluding cases have been treated by radium surface applications, with radium loaned by the Medical Research Council to the Middlesex Hospital for special investigations in cancer treatment.

### *Radium Cases (5).*

CASE 11.—F. P., aged 15. In June, 1923, there was a tumour behind the nipple with extension towards the right axilla. The mass was hard, slightly fixed to the overlying skin; there was a small gland in the right axilla. The mass measured 11 by 10 cm. Operation was refused. A prolonged series of applications with ¼ g. of radium element was given, at 4 cm. distance for 33 hours, spread over six months. In March, 1924, there was practically no residue to be felt. In February, 1925, only a slight apparently fibrous thickening remained as a residue of the former tumour.

CASE 12.—H. C., aged 65. This patient had a lump about the size of a five-shilling piece in her left breast, with slight retraction of the nipple. The skin was slightly adherent, and there was a gland in the left axilla. She refused operation, and was treated with 750 mg. of radium element for five hours in September, and again in October, 1921. Later on 17 applications of ¼ g. were given at three-weekly intervals, and radium treatment was also given to the left supraclavicular glands which had enlarged. In December, 1923, the tumour was only just palpable, and the supraclavicular glands were much smaller. Another treatment was given to the left breast in March, 1923. In the summer of 1923 the patient had a hemiplegia, but since her recovery from this she has come repeatedly for examination. In April, 1924, there was no definite tumour to be felt, but a diffuse thickening in the lower outer quadrant; the nipple was much retracted. Radium telangiectases were marked over the most prominent part of the breast. This patient has been followed for nearly four years, with good result.

(Any similar case would now be treated by radium cross-firing from a distance of 3–5 cm. at least, not by radium closely approximated to the skin, as in all the earlier applications in this case. Thereby the telangiectases would probably be avoided, and the base of the growth be more efficiently radiated.)

CASE 13.—M. J. K., aged 66. This patient had a hard mass in the upper and outer quadrant of the right breast; the skin was adherent. There was an enlarged gland in the right axilla. Operation, though possible, was considered inadvisable owing to the condition of the patient's heart, and she had glycosuria. Treatment began in April, 1924, by the ¼ g. of radium element for eight hours at 2 cm. distance; this was repeated in May, and again in September for 14 hours. In May, a hard skin nodule 2 cm. in diameter was found in the mid-axillary line just above the iliac crest. This nodule had radium application. On Sept. 10th neither the original tumour nor the nodule was palpable.

CASE 14.—S. M., aged 48. This patient noticed a small lump to the inner side of the nipple of the left breast in 1920. By May, 1924, it had enlarged and ulcerated through the skin. The patient had refused operation.

The nipple was retracted. The ulcerated mass was fixed to the chest wall. There were two small superficial nodules just above and to the inner side of the nipple. There was a hard gland in the left axilla. Half a gramme of radium element was applied on a dental wax applicator 2 cm. thick over the area, for a ten-hour dose divided over two days at intervals of two months four times. The axillary gland was also treated. By November the ulcer had completely healed, the growth was much smaller, and the skin nodules had disappeared. In February, 1925, 180 mg. of radium element was applied to the breast at 1 cm. distance for six hours; on this date the site of the original tumour could only be made out by very careful palpation, and the axillary gland could hardly be detected. Though the patient had refused an operation previously, strictly speaking this case was inoperable when first seen by us, unless a merely palliative operation had been carried out with post-operative radiation.

CASE 15.—M. H., aged 73. On March 4th, 1924, there was a hard mass measuring 4·5 cm. in diameter behind the nipple, fixed to the skin, but not to the chest wall. There were several skin nodules between the growth and the axilla. 400 mg. of radium were applied at a distance of 3 cm. for 18 hours in March and April, 1924, and treatment was also given in July and September, and in March, 1925. In September, 1924, the growth had become softer and smaller, and the skin nodules had disappeared. On Dec. 10th the growth was flattened, and its limits were not easy to define; a small gland was still palpable in the left axilla. On March 6th, 1925, the condition of the breast was very satisfactory, but she was found to have developed an abdominal swelling, which was diagnosed by Mr. Victor Bonney as metastatic carcinoma of the ovary following breast carcinoma.

All these five radium cases have done well locally, within the limits of the time they have been under observation. In each case there have been supplementary medium voltage X ray applications to the epigastrium, lateral chest wall and axilla, supraclavicular triangles, opposite axilla and breast.

Summarising the total 15 cases there have been two deaths, one due to an intercurrent disease, and one of the disease over two years after treatment had been discontinued; one case has an abdominal metastasis. Three are new cases, but in one of these there is now no sign of disease. One is having treatment for a radium dermatitis, the disease appearing arrested. The remaining eight have been in good general and local condition for some time. The periods of observation are too short for conclusions to be drawn as to technique or results, but the subject is brought forward because it should be discussed, and the results so far suggest that the alternative of radiation treatment can be safely offered to patients who refuse operation, or in whom operation is inadvisable.

Comparing the radium with the deep X ray cases, there is no notable difference so far in the results. The quantity of radium necessary for the thorough treatment of breast cases is so large that only a few cases can be treated with radium in any centres at present. Further supplies of radium are necessary if this country is to explore fully this method of treatment, especially as large quantities of radium, at a distance from the body, must be used in cases in whom all surgical interference is impossible, if the best results from surface radium are to be obtained.

In conclusion one point should be referred to. This is the diagnosis, in cases where there is no histological confirmation. Several writers lately have shown that a positive expert surgical diagnosis of breast cancer is correct in about 91 per cent. of cases. On this proportion one (or at most two) of this series may not have malignant disease. But practically every case showed at one time or other, in addition to characteristic signs in the primary growth, axillary or supraclavicular gland enlargement or skin nodules. And in this series no patients with mastitis and possibly very early carcinoma have been included; several cases of this nature have been treated so far with success.

Acknowledgments should be made to the Medical Research Council for their loan of radium, and to Mr. Gordon-Taylor, Mr. Eric Pearce Gould, and in particular to Mr. Handley (under whose care most of the patients were) for opportunities afforded and their interest in radiation therapy.

### *Notes taken on Dec. 8th, 1925.*

CASE 3, with an atrophic scirrhus, in the last two years fixed to the chest wall, who had begun treatment with low-voltage X ray applications (1918–19), has reported in the last weeks with a left-sided pleural effusion.

CASE 10.—The broad sickle-shaped area in the upper and outer part of the breast, which at first appeared to be a radium dermatitis, was just *outside* the two radium encirclements; and later the area ulcerated and was evidently a malignant invasion of the skin and underlying lymphatics. Later on the left supraclavicular glands, the opposite breast, and both pleuræ became invaded, and the patient died on Oct. 9th. The two medium-voltage X ray applications and the two radium encirclements had not been sufficient to arrest the disease in the breast.

CASE 14 had a radium dermatitis after the last treatment, but has been discharged from hospital with this now healing.

CASES 2, 4, 5, 7, 8, 9, 11, 12, 13, and 14 are well, with little or no sign of disease.

---

# THE STANDARDISATION OF TUBERCULIN AND THE PRECIPITIN TEST.

BY C. C. OKELL, *M.C.*, M.R.C.P. LOND.,

AND
J. B. BUXTON, M.A., F.R.C.V.S.,
INSTITUTE OF ANIMAL PATHOLOGY, UNIVERSITY OF CAMBRIDGE.

THE testing of tuberculin by methods based on the official test in use at Frankfort has been carried on in England for many years. Eagleton and Baxter (1923) used the official Frankfort method, in which varying doses of tuberculin are injected subcutaneously into different tuberculous guinea-pigs until the lethal dose is found; they added the von Pirquet and intracutaneous tests and thereby considerably improved the method.

With the methods at present available the degree of accuracy attainable is of a different order from that ordinarily obtained in the testing of diphtheria and tetanus toxins and their antitoxic sera, which lend themselves to accurate titration, but the test nevertheless distinguishes at least a "satisfactory" from a "useless" tuberculin. It is probable that an experienced worker can differentiate, on a short range of tests, between three tuberculins of values 100 per cent.—i.e., equal to standard tuberculin—60 and 30 per cent.; on a long range of tests smaller differences probably can be detected.

The standard tuberculins used in the work in England have been based upon those of Frankfort since the receipt of the first standard from Ehrlich several years before the war, and many different batches of tuberculous guinea-pigs have been used with fairly consistent results.

Dreyer and Vollum (1924) described a precipitin test and found that considerable discrepancies might exist between the results obtained by the guinea-pig method and the precipitin test. Table I. summarises these results.

TABLE I.

A = Description in Table VII. (Dreyer and Vollum, 1924).
B = Value by precipitin test (Dreyer and Vollum).
C = Value by guinea-pig test (Okell and Parish).

| A. | B. | C. |
|---|---|---|
| British 3 .. .. | 33·2 | 100 |
| „ 4 .. .. | 46·0 | 100 |
| „ 5 .. .. | 244·7 | 100 |
| American 29 .. | 131·3 | 10 |
| Belgian 30 .. | 19·8 | 5 |
| British 2 .. .. | 135·1 | 100 |
| „ 8 .. .. | 119·6 | 100 |
| „ 9 .. .. | 95·2 | 100 |
| „ 12 .. .. | 117·8 | 100 |
| „ 26 .. .. | 6·1 | 10 |
| American 27 .. | 14·8 | 10 |
| „ 28 .. | 29·6 | 20 |
| French 31.. .. | 18·3 | 10 |

It therefore became of fundamental importance to discover whether tuberculins found to be equal (within the error of the test) to standard by the official Frankfort test on guinea-pigs could vary widely in their content of the active principles of "tuberculin," the substance used for the detection of tuberculosis in man and animals. A joint investigation was therefore arranged. It was agreed that one of the workers at the Wellcome Physiological Research Laboratories should choose from materials available at the laboratories three tuberculins, and should hand them to the various workers, each of whom would know nothing of the value of the tuberculins or of results obtained by the other workers until he had made his final report.

TABLE II.

| Col. 1. | Col. 2. | Col. 3. | Col. 4. | Col. 5. | Col. 6. | Col. 7. |
|---|---|---|---|---|---|---|
| Tuberculins. | Original values (Okell and Parish). | Parish. | Cummins. | Buxton. | Dreyer and Vollum. | Okell and Miss Steed. |
| | T.B. guinea-pigs, subcutaneous, von Pirquet and intracutaneous. | | Human patients: cutaneous test. | Tuberculous cows: intradermic test. | Flocculation test. | |
| 1232 | 5–10 | About 5. | Both weak and inefficient. | Poor. | 100 | 100 |
| 1360 | 2½–5 | About 2½. | | Useless. | 59 | 50 |
| 1366 | 100 = Frankfort standard. | 100 | Thoroughly reliable; powerful tuberculin. | Full potency. | 14 | 12 |

*Col. 1.*—The original batch numbers of the tuberculins.

*Col. 2.*—These values were, prior to the present joint investigation, given by Okell and Parish as the results of many tests by the subcutaneous, intradermic, and von Pirquet methods applied on many occasions over a period of about 18 months. The values obtained by the three methods on the tuberculous guinea-pig agree fairly closely.

*Col. 7.*—Precipitin tests by Okell and Miss Steed. Vollum provided a generous supply of the precipitating serum. Okell and Miss Steed report "on precipitin test 1232 markedly better than 1360 or 1366. 1360 is definitely better than 1366." The arbitrary values given are the averages of two series of readings amongst which rather wide fluctuations occurred. These figures correspond fairly closely to those in Col. 6.

The three tuberculins were 1366, a Koch's old tuberculin made on the ordinary glycerine veal broth medium, 1360, and 1232. These two latter had been made in the ordinary way from strains of *B. tuberculosis* grown as a film on glycerine veal broth in the expectation that good tuberculin would result. When the filtrates had been concentrated and batches of the desired Koch's old tuberculin had resulted, the "tuberculin" failed to pass the ordinary animal test. Further examination by the various guinea-pig tests indicated that the "tuberculin" values of these two batches were very low—approximately 2 to 5 per cent. and 5 to 10 per cent.

In order that the various workers should use the same technique, Dreyer and Vollum arranged a full demonstration of the details of the precipitin test at Oxford. This enabled Okell, with the help of Miss G. I. Steed, to carry out three precipitin tests on the three tuberculins. These latter workers with their limited experience of this test would not attach undue importance to the accuracy of their figures obtained by the precipitin method. However, in their three tests they always placed the three tuberculins in the same order of merit (Col. 7) as Dreyer and Vollum (Col. 6, Table II.).

Cummins carried out the testing of the three tuberculins on a number of patients. He decided to test out these tuberculins in a series of dilutions as [illegible]y suggested by Dreyer and according to the [illegible]ue described by himself (1924). This same technique was used by Dreyer and Vollum in the "human cutaneous test" described in their paper. Twenty patients affected with various forms of tuberculosis, and suitable controls, were used in the investigation. An examination of the records of the local reactions led Cummins to report before he had any further details relating to the tuberculins, that "1366 is a very efficient preparation, superior in every way to 1360 and 1232. The two latter samples are indeed so poor in reaction value as to be useless and misleading for clinical purposes."

Buxton tested the three tuberculins on tuberculous cows in various dilutions by the "repeat intradermic test" (as described by himself (1925)). His conclusions are given in Col. 5 of Table II.

The results of the joint investigation are given in Table II. It will be seen that the official Frankfort or "guinea-pig" method, the intracutaneous and von Pirquet tests in guinea-pigs, the cutaneous method in human beings, and the intracutaneous test on tuberculous cows all agreed in indicating that 1366 was a satisfactory tuberculin, and that 1360 and 1232 were practically worthless, while the precipitin method suggested that if 1232 was a tuberculin of precipitin value 100, 1366 had a value of only 12 and 1360 of 50.

With reference to the precipitin method, the results of Mueller (1925) and of Laidlaw (1925) indicate that the active principle of "tuberculin" and the substances precipitable by an antiserum, are probably two distinct substances, separable by chemical methods.

### *Summary.*

1. The precipitin test does not necessarily measure the active principle of tuberculin on which its use in the various methods of diagnosis of tuberculosis depends.

2. Satisfactory agreement in precipitin unit value was obtained by two different groups of workers by the precipitin test. This test apparently measures with a considerable degree of accuracy a substance probably other than the active principle of tuberculin, and presumably the interesting precipitable substance of Mueller and Laidlaw?

3. The "tuberculin" value of tuberculins which have been standardised by the official Frankfort method cannot in all cases be deduced from the precipitin test.

4. The results obtained by subcutaneous, intracutaneous, and von Pirquet tests on guinea-pigs and by the tests on tuberculous human beings and cows were in agreement. By these three methods a tuberculin of standard strength and two others of values approximately 10 and 5 per cent. of standard were placed correctly in order of merit.

# THE DIAGNOSIS AND TREATMENT OF INTRATHORACIC NEW GROWTHS.

*Opening a Discussion at the Royal Society of Medicine on Feb. 23rd.*

BY L. S. T. BURRELL, M.D.CAMB., F.R.C.P.LOND.,
ASSISTANT PHYSICIAN, WEST LONDON HOSPITAL; PHYSICIAN, HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON.

A FEW years ago a discussion on intrathoracic new growths would have been of academic interest only. An uncommon condition but rarely diagnosed, at any rate until the very late stages, and when diagnosed untreatable. The condition, however, is not so rare as was supposed, and with improved methods of diagnosis many cases are now recognised which formerly would have been considered to have been cases of some other disease—usually tuberculosis. These tumours may be considered under three headings: (1) those of the mediastinum; (2) those of the pleura; (3) those of the lung. In all cases the growth may be primary or secondary, malignant or benign. In the case of secondary tumours the diagnosis is, as a rule, easy, but they are generally beyond cure. A primary growth, however, may often be successfully removed by operation, even if malignant. The benign tumours especially lend themselves to successful operation, and as these usually increase in size and eventually prove fatal, it is very important to deal with them in the early stages.

### *Tumours of the Mediastinum.*

Sarcoma is the most common primary growth, but a secondary carcinoma is frequently found. Of the *non-malignant* cases fibroma and dermoid are the least uncommon. Sometimes the tumour grows very rapidly, so that even after a few weeks the whole chest may be a mass of new growth. In the late stages, of course, the diagnosis is obvious. In the early stage the first sign is the result of pressure. Some time ago I saw a man who complained of swelling of the veins of the right side of the neck when he stooped; otherwise he was quite well. I could find no physical signs but suspected mediastinal tumour from the symptom, and X rays showed a mass in the superior mediastinum. He had a course of X ray therapy, but the tumour spread and he died seven months after the first symptom. Post mortem he was found to have an enormous sarcoma in the mediastinum involving most of the right lung and the pericardium, with secondary masses in the left lung. In this case the diagnosis was made early, and I much regret that I did not consult a surgeon.

In a second case the patient complained of swelling of most of the joints, was unable to walk, and was wheeled into the hospital as a case of rheumatism. He denied cough or any chest symptom, but as his fingers were very clubbed I suspected an intrathoracic lesion, and on examination found dullness between the scapulæ and a very obvious D'Espine sign. X rays showed a large mediastinal mass. After treatment with X rays this mass disappeared and all the joint symptoms cleared up though the clubbing remained. He kept well for about a year, when glands appeared in the groins and were found to be lymphadenomatous. In this case the growth had reached such a size that it could readily be recognised by clinical examination, before any symptoms except the arthropathy had appeared. In the first case the pressure signs came before any physical signs could be detected. In both cases, however, X rays confirmed the diagnosis. Pleural effusion usually appears early in these cases, but not as a rule until other signs have been noticed. Dyspnœa and pain are also early symptoms, but may be absent until the late stages. There is, indeed, no early sign or symptom which is constant, but one should always be on the look-out, and the slightest symptom suggesting pressure in the mediastinum should make one very suspicious. Having made the diagnosis it is important to exclude syphilis or aneurysm as the cause, and if these can be excluded I think a surgeon should be called in as soon as possible.

### *Tumours of the Pleura.*

The type most frequently seen here is endothelioma. Usually the first symptom is dyspnœa, which is found to result from a large pleural effusion. I saw a case last year in a youth of 20. He suddenly developed what was thought to be a bad cold and went to bed owing to increasing dyspnœa. Pleural effusion was found and was aspirated many times, but the fluid always re-formed rapidly and he died six months after the onset of the first symptom. In this case the diagnosis was made (and it was confirmed at the post mortem) solely on the quantity of the fluid and the rapidity with which it formed. The fluid was clear throughout in this case, but usually it becomes blood-stained sooner or later. On the other hand, I have frequently seen a blood-stained effusion which was not caused by neoplasm. It is often blood-stained in cases of tuberculosis.

### *Tumours of the Lung.*

Primary carcinoma of lung occurs in about 1 per cent. of all cases of carcinoma. It is said that tuberculosis is a predisposing cause, and certainly this disease is often present in cases of carcinoma of lung. Moreover, in 80 per cent. of cases the upper lobe is involved, so that the diagnosis may be of the greatest difficulty, especially if tubercle bacilli are present in the sputum. If a diagnosis is made early enough carcinoma of lung may be, and has been, successfully treated by operation. In order to arrive at an early diagnosis it is important to be on the look-out for neoplasm; many cases are missed because they are never suspected. Secondly, one should rid oneself of the old fallacy that the absence of tubercle bacilli in the sputum means nothing. In any case of pulmonary disease where there is sputum repeated failure to find tubercle bacilli should lead one to suspect—and very strongly—that the disease may not be one of pulmonary tuberculosis even if the signs are definite and confined to the apex of a lung. Thirdly, whenever the signs or symptoms are unusual, neoplasm should be suspected. It should not be forgotten that in some 90 per cent. of cases the disease starts in a bronchus. Bronchoscopy, therefore, is of the greatest value in the early recognition of these growths. Not only is it sometimes possible to see the growth, but a suspicious piece of the bronchial mucosa may be removed for microscopical examination. To illustrate some points in diagnosis I will give a brief account of a case of carcinoma of lung that I saw recently. A woman of 55 had been ailing for 18 months, and since influenza five months ago had been worse. She had lost 2 st. in weight, had night sweats, and a cough with purulent blood-stained sputum. She had been advised to go into a sanatorium several months before but had refused. Now, however, finding herself worse she had consented, and it was with a view to arranging sanatorium treatment that she came to me. On examination I found that the signs were confined to the left lung. In front from the clavicle to the third space crepitations were heard, the breath sounds were bronchial, and the percussion note impaired. Below this until the fifth space the breath sounds were absent and the percussion note stony dull. Now the history was quite typical of tuberculosis, but there were two facts which made the diagnosis doubtful. The first that tubercle bacilli had never been found in the sputum, and the second the signs, although at the apex, were not those usually found in tuberculosis. The patient was therefore admitted to hospital and the X rays showed a definite dense round shadow in the middle of the left lung. This mass was clearly a tumour, and it was important to decide whether it was in the lung tissue or not. Some lipiodol was injected into the trachea with the patient lying on the left side, and the X ray photograph showed the left bronchus well defined for a short distance, when it suddenly stops. It could also be seen that the lipiodol had overflowed into the normal right bronchial tree. So far the case appeared to be one of carcinoma of lung with occlusion of the bronchus.

An artificial pneumothorax was induced, and it was found that the lung collapsed around the mass, as is seen in the next X ray. Examination with the thoracoscope showed the presence of a large neoplasm in the lung tissue. Owing to the size of the growth, the length of history, and the bad general condition of the patient it was decided not to advise an operation. The patient died shortly afterwards, and at the post-mortem there was found a large carcinoma of lung with occlusion of a large bronchus, as was shown so well after the injection of the lipiodol. Just before death she developed a secondary growth of brain—not an uncommon site in these cases. I did not have a bronchoscopic examination because the diagnosis was clear without one, but had the condition been suspected a year earlier the growth would probably have been detected by the bronchoscope and she might have been saved by operation.

I have been able to do little more than touch upon my subject from the physician's point of view. Mr. J. E. H. Roberts is to speak after me, and I have left it to him to discuss the surgical methods and the chances of life they offer to the patients (see p. 468). As a physician, however, I must emphasise the fact that however dangerous an operation may be it is our duty to weigh this danger against the danger of leaving the patient alone, which in almost all of these cases is certain death. Operation cannot hope to succeed when metastases have appeared, and they start early. I should say, then, lose no time in confirming your diagnosis, and when once it is confirmed call in a surgeon and do not waste time in giving a trial to radium or any other form of treatment. Moreover, remember that non-malignant growths such as a dermoid or fibroma often prove fatal if left too long. I have laid stress on the value of X rays in diagnosis and have pointed out how the introduction of lipiodol or the induction of a pneumothorax may assist the X rays, but I have left it to Dr. Stanley Melville to describe this part of the subject in detail, and especially as regards treatment. In my experience X ray therapy is very good in cases of lymphadenoma and sarcoma and should always be used. For other forms of intrathoracic growth I have found X rays and radium therapy disappointing, but they should be tried in cases which are inoperable. When operation is possible it should be tried first. With regard to drugs, except in the case of gumma (and I have warned you that syphilis must be excluded before coming to a final diagnosis) they are of value only to alleviate symptoms.

In these cases the great function of the physician is to make an early diagnosis, and for this purpose I should say the most important factors are to suspect the unusual in every case of chest disease and not to rest satisfied with a diagnosis, however probable, until it is absolutely confirmed after a complete examination.

### CASE OF

# RUPTURE OF THE THORACIC AORTA.

By J. H. SHELDON, M.D., M.R.C.P. Lond.,

HON. PHYSICIAN TO THE WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.

*With Post-mortem Notes by*

S. C. DYKE, D.M. Oxf., M.R.C.P. Lond.,

CONSULTING PATHOLOGIST TO THE HOSPITAL.

Rupture of the aorta through an atheromatous plaque, though an uncommon, is by no means a previously unknown event. As in the case here recorded, death does not as a rule follow immediately upon the rupture. The interval of a few days between the symptoms due to the primary outrush of blood and the second set of symptoms just before death, due to the spread of the hæmorrhage, is usual. In most of the recorded cases the blood in the second [illegible]tal hæmorrhage had reached the pericardial sac; for it to pass between the pleura and the chest wall as in this case would appear to be excessively rare. At any rate no record of this phenomenon has been found in the literature available.

## *Clinical History.*

T. C., a man, aged 51, was admitted to hospital on Sept. 18th, 1925. He had been in perfect health till some six months previously, doing heavy work in a corn mill till 1916, serving in France from 1916 till 1919, and working as a motor-lorry driver since. He had been receiving treatment from his private doctor for the last six months, at first for bronchitis, but latterly for symptoms of gastric origin—anorexia, especially for fats, chronic abdominal pain, and vomiting after meals. A tentative diagnosis of carcinoma of the stomach had been made, and a barium meal was given at the beginning of August, but revealed nothing abnormal. On Sept. 17th, 1925, while driving his lorry, he had a sudden attack of severe pain in the epigastrium, followed immediately by vomiting. He recovered sufficiently to drive his lorry home—a distance of eight miles—although the pain was increasing in severity and had spread from the epigastrium to the left scapula. He passed the night in great pain, and was admitted to hospital the next day.

*Condition on Admission.*—When first seen he was pale, short of breath, and very restless. Nothing abnormal could be made out in the abdomen, except for slight tenderness, and resistance to deep pressure in the epigastrium.

Heart: The heart sounds were normal. The cardiac dullness on the right extended to one inch beyond the right border of the sternum, whilst upwards and to the left its borders could not be determined, as they were continuous with the big area of dullness described below. The apex-beat, however, was clearly felt a quarter inch internal to the nipple in the fifth left interspace. It was of normal character. Pulse 112, regular, and equal on both sides. The artery wall felt somewhat thickened.

Urine: Nothing abnormal noted.

Lungs: The right lung was normal. On the left side there was a large area of absolute dullness involving roughly the upper two-thirds of the chest, back and front. In front it extended from the clavicle down to the fifth interspace, and thence it extended outwards horizontally across the axilla to the seventh rib behind. Below this area the physical signs were normal. Over the dull area the breath sounds and tactile fremitus were entirely lost.

The chest was explored in the posterior axillary line at the lower limit of the dullness and bright blood was obtained.

The pain and the restlessness both diminished rapidly after the exploration, and he was able to sit up and move about in bed without any respiratory distress. The area of dullness, however, extended until by Sept. 22nd it involved the whole of the left side of the chest, accompanied by absence of breath sounds and of tactile fremitus. The position of the right border of the heart, however, remained the same as on admission. On the 23rd the chest was screened by Dr. G. E. Dyas, who reported a marked opacity of the left side of the chest, with a slight displacement of the heart and trachea to the right. He died suddenly, with hardly any warning, on the 25th, nine days after the commencement of the illness.

The Wassermann reaction of the blood was done twice and was negative on each occasion. By the courtesy of Dr. J. Menton a Sigma test and a Kahn test were done, these also being negative.

## *Post-mortem Examination by* S. C. DYKE.

The body was that of a well-nourished male of middle age. On opening the thoracic cavity two large extravasations of blood were apparent, both on the left side. The first of these was confined to the upper, the second to the lower part of the thoracic cavity; the upper one, although intrathoracic, was extrapleural; the second lower collection of blood was within the pleural cavity. It was apparent from the firmness of the clot and the presence of serum that the upper extrapleural collection of blood had been present for some days; the blood constituting the lower intrapleural extravasation had apparently only recently clotted and could not have been present for more than a few hours.

The upper collection of blood had apparently come from the neighbourhood of the great vessels at the base of the heart and had attained its extrapleural position by stripping the parietal pleura from the chest wall. The pleura had remained attached to the base of the heart, but had been stripped off the dome of the chest and the sides and back of the thoracic cavity so far down as the costal attachment of the diaphragm. The upper extrapleural collection of blood was therefore contained in a space bounded on the inner side by the heart and the structures of the mediastinum, on its remaining sides by the walls of the thoracic cavity, and at its base by the stripped-off parietal pleura. In this stripped-off pleura, at about the level of the fourth rib, was a rent about 3 inches in length, and it was apparent that it was through this rent that the hæmorrhage giving rise to the second intrapleural collection of blood had taken place. This rent had presumably originated in the puncture of the stripped-off pleura by the exploring needle on the previous day. The presence of the two hæmorrhages had served to collapse the left lung, to push the heart slightly over to the right side, and to thrust down the dome of the diaphragm on the left side.

On opening the pericardial sac no contained blood was found. The heart was large and the left ventricle showed distinct hypertrophy of the walls. Otherwise no abnormality was present. No extravasation of blood was present in the tissues of the anterior mediastinum, but on removing the heart and lungs it was apparent that blood had found its way generally throughout the posterior mediastinum, more particularly in its upper part; this blood was for the most part lying in the areolar tissue supporting the various structures. The most intense degree of extravasation had occurred into the walls of the aorta, the blood having found its way between the media and adventitia with the result that throughout the whole length of the thoracic aorta these two coats were completely separated by a lamina of blood-clot. This layer of clot was thickest in the neighbourhood of the arch, where it attained a depth of 10 mm.; from there it dwindled in thickness down to the diaphragm; the abdominal aorta was not affected.

On opening the aorta a condition of the most intense atheroma was disclosed. Numerous large calcareous plaques were present, and throughout, the intima was the subject of fatty change. On the posterior surface of the vessel just below the arch was a linear tear 20 mm. in length through both intima and media, running in the long axis of the vessel. This tear, through which it was evident that the extravasation of blood had taken place, extended upwards from an atheromatous plaque, which was presumably the site at which the wall had originally given way.

With the exception of the kidneys all the other organs were apparently normal. The kidneys were small, and on section showed considerable diminution in depth of the cortex; the capsule stripped fairly readily, exposing the granular surface characteristic of "primary chronic interstitial nephritis." Histologically both kidneys showed a moderate degree of fibrosis and round-celled infiltration of the interstitial tissue; the glomeruli were entirely free from any evidence of inflammation. The smaller vessels showed to an extreme degree that fatty change of the intima universally associated with "chronic interstitial nephritis."

### *Comment.*

In most of the recorded cases it would appear that after the primary rupture of the intima and media the spread of the hæmorrhage was limited by the adventitia, death being brought about by the later rupture of this last coat. In the case recorded above the rôle usually sustained by the adventitia alone was in part taken on by the parietal pleura which was stripped off the ribs by the hæmorrhage. It was the rupture of this membrane in this case and not, as is usual, rupture of the adventitia which was the immediate cause of death.

The atheromatous condition of the aorta in this case was apparently a part of the diffuse disease of the intima of the vasculature which is always associated with "primary chronic interstitial nephritis." It has already been pointed out that fatty change of the intima of the smaller vessels was a marked feature in microscopical sections of the kidney, and the same applied to the spleen, the only other organ examined. In "primary chronic interstitial nephritis" this fatty change of the intima of the smaller vessels of the kidney is unfailingly present; it is usually present to some extent in the aorta also, though rarely to the extent shown in this case. The cerebral vessels are also often affected, rupture of these as a result of the condition being, of course, a far commoner event than rupture of the aorta.

The absence of any history and the negative results of all the diagnostic tests may be taken as definitely excluding any syphilitic element in the case.

# DIVERTICULITIS AND ITS SURGICAL TREATMENT.*

BY J. P. LOCKHART-MUMMERY, F.R.C.S. ENG.,
SENIOR SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM, ETC.

ALTHOUGH diverticulitis is by no means a rare condition, it is only within recent years that it has been recognised and fully described, and even now it will not be found mentioned in many of the text-books on medicine. It is a condition of the latter half of life, due to the formation of small hernial protrusions from the lumen of the bowel through the muscular coat. These pouches, or diverticula, may be found in any part of the alimentary canal (except possibly the rectum), but are most common in the large intestine, and particularly in the pelvic portion.

We have to recognise two distinct conditions due to pouching of the walls of the large gut. Diverticulosis, a condition in which there are numerous small pouches or hernial protrusions in the walls of the colon, which are demonstrable by examination with a barium enema under the X rays, but which is not accompanied by any symptoms referable to the diverticula. Dr. E. I. Spriggs, at Duff House, found that 10 per cent. of the patients examined by X rays in that institution showed well-marked evidence of diverticulosis. The average age of the patients examined was 45, and they had all come to the institution for the relief of some abdominal condition, so that we can say that 10 per cent. is probably much too high a figure if applied to the generality of persons.

The other condition is that of diverticulitis, in which secondary inflammatory changes have taken place in the diverticula, and definite symptoms attributable to these changes are complained of by the patient. The great importance of detecting the condition in its earliest stages before serious inflammatory changes have taken place will be readily appreciated, and in this connexion Dr. Spriggs's valuable investigations have done a great deal to throw light on the subject. No doubt routine examinations and careful treatment will, in the future, do much to prevent the condition of diverticulosis from developing into the more serious condition of diverticulitis.

It is the latter condition which chiefly concerns us here, and I will confine my remarks chiefly to the means of dealing with it.

Of my 41 cases, 25 were men and 16 women. This agrees with Dr. Spriggs's figures for diverticulosis of 71 men and 20 women. The average age of my cases was 60, and the youngest case was 42. Dr. Spriggs suggests that the cause of the condition is the habitual use of aperients, but the fact that the condition is commoner in men than in women seems to disprove this, as there can be no doubt that the habitual use of aperients is much commoner with women.

### *Symptoms.*

In the early stages of any abdominal disease the symptoms tend to be very vague and uncertain. Vague pain in the abdomen, discomfort, slight disturbance of the bowel actions, are all too uncertain to be of much value, though if they lead the doctor to have the colon examined by X rays may reveal the condition. The typical symptoms of a developed diverticulitis are attacks of pain and tenderness over some portion of the colon, usually the sigmoid flexure, accompanied by a slight rise of temperature. Symptoms of chronic obstruction of the bowels accompanied sometimes by the presence of a palpable tumour, felt either through the abdominal wall or per rectum by bimanual examination, may be present and will closely simulate carcinoma, but may be distinguished from it as a rule by the accompanying tenderness and signs of inflammation. The attacks may be at long intervals and there may be a history of difficulty with the bowels extending over a period of years. The diagnosis is often very difficult, but a bimanual examination of the pelvis will often enable a mass to be felt, and the sigmoidoscope gives useful information in some cases. A barium enema, if properly done, is of the utmost value, but only the very best X rays are of any use if the diverticula are to be seen. I am frequently having cases sent to me with X ray photographs of the colon showing nothing abnormal, and when the patient is photographed again in the proper way numerous diverticula are easily demonstrated.

---

* An address read before the Sutton and Wallington Medical Society, Jan. 29th, 1920.

To obtain proper photographs certain things are essential. The photograph must be taken instantaneously, or the movements of the colon will blur the photograph and hide the diverticula. Also, the enema should be made up with a thin medium, such as butter-milk. It is also very important that the patient should be photographed some 12 hours after the enema has been evacuated, as, while the enema is in place, only those diverticula can be seen which are situated at the edge of the bowel. After the bowel has been emptied the diverticula can be seen as opaque round objects in the line of the bowel and give rise to an appearance which is quite characteristic and unlike anything else. By far the commonest situation for the diverticula to cause trouble is in the pelvic colon. Thus, out of 41 cases of my own the distribution was as follows: sigmoid only, 36; transverse colon, 3; cæcum, 1; ascending colon, 1. Once the diverticula have formed and become full of hard fæcal material, the inflammatory changes due to the irritation of a foreign body within the thin-walled diverticulum sooner or later occur and set up secondary changes.

The tendency is for one or more of the diverticula to perforate. Perforation may occur from sloughing of a concretion through the thin wall of the diverticulum, from gangrene of the diverticulum, or from the formation of a local abscess, which subsequently bursts into the peritoneal cavity or some other viscus. The latter, in my experience, is the most usual. Perforation into the bladder is not uncommon, and I have met with three cases out of 41. An intense cystitis results with the passage of flatus and fæces per urethram.

Perforation, with the formation of local abscesses in the pelvis and one or more openings on the abdominal wall, is not uncommon. One of the great troubles of such cases is that the abscesses are nearly always multiple, and proper drainage cannot readily be established. It is rather like trying to drain a sponge. Fresh abscesses keep forming in the midst of a dense mass of hard fibrous tissue, and such cases are the cause of much anxiety and are most unsatisfactory to treat. I had one case in which there were as many as five different sinuses in the abdominal wall, all leading down to a dense mass of fibrous tissue. This condition lasted for several years, and ultimately malignant changes occurred in the skin with fatal results.

### *Association of Diverticula with Tumour Formation.*

The greatest interest attaches to those cases in which there is tumour formation from the deposit of dense fibrous tissue around the inflamed diverticula. Such tumours often reach a considerable size, and are almost invariably fixed and adherent to other structures. These cases are frequently confused with malignant disease, and even when the surgeon is able to handle the tumour from inside the abdomen it is not always possible to be sure whether the case is one of cancer or diverticulitis. Evidence of inflammation and the presence of diverticula in other parts of the colon will help, but such evidence is not always present.

Two distinct types of tumour may be recognised from a pathological point of view. In the more usual type, on laying open the tumour there are several large diverticula containing concretions surrounded by an irregular mass of very hard fibrous see Figs. 1 and 2). In the other type, which in my experience is less usual, the tumour consists of a dense mass of cartilaginous tissue of a pale grey colour, through which can be traced numerous very narrow channels representing diverticula. These channels are so narrow that they will only admit a bristle, and large cavities are seldom seen. (Fig. 3.) The density of the cartilage in these cases is surprising, and much resembles a cartilaginous tumour, so that it is hardly surprising that many of them have been mistaken for new growths. These tumours are always adherent to others structures, and are generally situated at, or near, the middle of the sigmoid flexure. Their removal is a matter of considerable difficulty, but can often be successfully managed if their true nature is recognised. Unfortunately, they are often mistaken for malignant disease, and, of course, as such are not worth attempting to remove as they are adherent to other structures. Cases of so-called cancer of the bowel, that have recovered after a simple colostomy, are mostly accounted for in this way.

### *Treatment.*

The surgical treatment of diverticulitis presents many serious difficulties. Naturally, it is only when serious secondary inflammatory changes have occurred that the surgeon is asked to interfere. The indications for surgical interference are in my opinion: (1) Persistent attacks of pain and tenderness in spite of careful medical treatment, the latter being directed to keeping the bowel contents liquid, and general means to improve the patient's resistance, rest, dieting, &c. (2) Attacks of threatened obstruction of the colon. (3) The presence of a palpable tumour in the colon. (4) Evidence of threatened perforation into the bladder, such as attacks of pain in the left iliac fossa accompanied by frequent and painful micturition. (5) Evidence of perforation with abscess formation or peritonitis. One of the great difficulties of dealing with these cases is that the tissues are of necessity highly septic, and that there is a danger of setting up peritonitis by breaking down adhesions in attempting to free the damaged bowel.

The ideal treatment, when the condition is localised to the middle of the sigmoid and a tumour has formed, is resection of the affected colon with end-to-end anastomosis. This is in many cases a distinctly risky procedure, but as often the only alternative is a permanent colostomy, a certain amount of risk is justifiable. The following is a good instance of such a case:—

A lady, aged 56, was sent to me with a large, hard, and very tender tumour in the sigmoid flexure, which could be felt through the abdominal wall and bimanually. A diagnosis of diverticulitis was made, and I opened the abdomen. I found a large mass in the sigmoid densely adherent to the back of the uterus and to the left Fallopian tube. I removed it with some difficulty, together with the uterus and tube, and joined the bowel end to end. A temporary cæcostomy, with a rubber tube, was established and the abdomen closed with a wick drain. The patient made an uninterrupted recovery, the cæcostomy opening closing on the twelfth day.

In another case a lady of 48 had a similar tumour, and on opening the abdomen I found that a perforation had already occurred into the left Fallopian tube, which was full of pus. The tumour was removed after evacuating the pus and the bowel joined end to end with temporary cæcostomy in the same way. This patient also recovered without any bad symptoms. In both these cases there were no evident diverticula in any other part of the colon. The specimens from both these cases are illustrated in Figs. 1 and 2.

I have, in all, resected the sigmoid for diverticulitis ten times, eight times with immediate end-to-end anastomosis and twice with colostomy. There is no doubt that resection with anastomosis gives the best results, and is the only method, once a tumour has formed, which cures the patient and leaves him in a normal condition.

The safest procedure, and that which most often has to be done, is colostomy above the site of obstruction, or perforation, as the case may be. As a rule, the colostomy opening should be established in the transverse colon, so as to be well away from the disease and not liable to become involved in the adhesions. Occasionally, in the course of time, the condition may subside sufficiently to enable a subsequent resection to be performed, but this is not often possible. The results where a colostomy is done in time—that is to say, before the sepsis has reached too advanced a stage—are excellent. The inflammatory mischief gradually subsides and all symptoms disappear. The bowel, however, strictures up almost completely as a rule, and apart from resection there is no hope of subsequently closing the colostomy.

The obvious question that suggests itself is what possibilities are there between these two measures—resection and anastomosis and a permanent colostomy? There are several possibilities more or less satisfactory. One is to perform an ileo-sigmoidostomy, so as to short-circuit the damaged bowel. It is only in a very few cases that there is sufficient healthy bowel below the damaged portion to render this possible; also, there is a serious danger of the anastomosis becoming subsequently involved in the adhesions and inflammatory mischief around the diverticula. This happened in one of my cases, and colostomy had to be performed to relieve the condition.

Another plan, which I have carried out successfully in several cases, is to free the involved portion of bowel very carefully by breaking down the adhesions, if necessary removing any very prominent diverticulum, and to draw the damaged bowel well up on to the ileum and wrap it well up in a fold of omentum drawn down for the purpose. This prevents the inflamed bowel from becoming again adherent to the bladder or small intestine, and makes it probable that, should a local abscess or perforation occur, it will remain localised to the iliac fossa, where it can be more safely dealt with. The patients that I have treated in this way have kept well by being very careful to keep the contents of their colons absolutely liquid, and the thickening in the colon has subsided in the course of time so much that it is not now palpable. This is not, of course, a very radical method of treatment, but it has certainly saved several patients from a colostomy, and they themselves have been very pleased with the result. It is, of course, not available when obstructive symptoms have already shown themselves, and it is quite possible that some of these patients may eventually get obstruction and require colostomy.

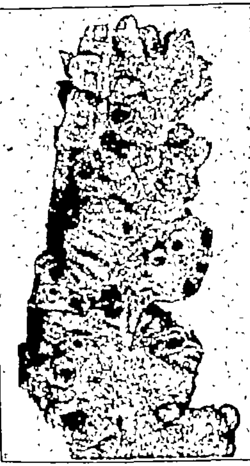
*Results.*

Out of 41 cases which I have had to treat surgically, in 32 some form of radical operation was performed apart from merely opening abscesses.

| | Cases. | | Deaths. |
|---|---|---|---|
| Colostomy .. .. .. .. | 13 | .... | 0 |
| Resection and colostomy .. .. | 9 | .... | 1 |
| Resection and end-to-end anastomosis | 8 | .... | 2 |
| Freeing adhesions and removal of one or more diverticula .. .. .. | 9 | .... | 1 |
| Simple drainage and cæcostomy .. | 2 | .... | 0 |

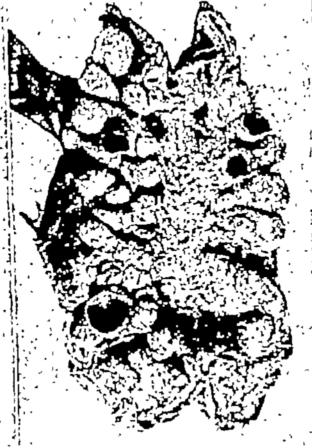
It will be seen that by far the safest method is colostomy well away from the seat of the trouble.

FIG. 1.



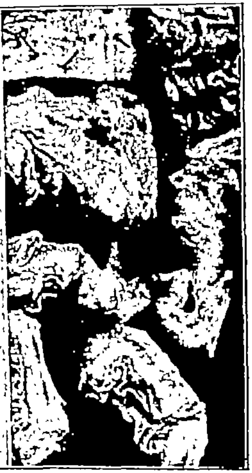
Specimen showing numerous diverticula, some of which have been cut open, and dense fibrous tissue. This tumour was successfully resected and the patient has remained well.

FIG. 2.



Specimen of diverticulitis of the colon showing diverticula, some of which are laid open. This tumour was successfully resected.

FIG. 3.



Specimen showing dense cartilaginous thickening of the colon wall due to diverticulitis. Tumour successfully resected.

All these patients did well, except one who developed cancer in an old sinus and died two years later. The others all got quite well and all symptoms subsided. Some are still in good health, 10 and 11 years after operation. The objections to this operation are, of course, obvious. Of the eight cases treated by resection, two died, both from lung complications. The others have remained quite well, and there is no doubt that this is the ideal method when possible, which, unfortunately, is not often the case. Of the nine cases treated by freeing adhesions, one died from sepsis. There is always danger in these cases, even in disturbing the adhesions. The others have remained well with occasional slight attacks of pain, but up to date with no serious complications. In one case a diverticulum in the transverse colon leaked and set up general peritonitis; the patient was a lady of 70. I drained the pelvis and the perforation and performed a cæcostomy. This patient recovered. Another case was that of an elderly gentleman, who had a perforation of a diverticulum of the ascending colon and general peritonitis. He was not operated upon till four days after the perforation, but recovered with free drainage and was quite well five years later.

### *Summary.*

Diverticulitis is a condition which, if detected in its early stages and properly treated, may be so kept in check that surgical interference will not be necessary, or may be much delayed. In its fully developed condition it is a very grave disease with most serious possibilities, and surgical interference is indicated before the more serious complications have taken place.

Operations for diverticulitis are both difficult and dangerous. Interference with the diseased bowel may easily set up grave sepsis or result in a fæcal fistula, and great care and judgment is necessary. Colostomy well away from the trouble is the safest procedure and should not be dangerous if the diseased bowel is not too thoroughly explored, or not explored at all.

Resection with end-to-end anastomosis and temporary cæcostomy is the ideal treatment, and the results I have obtained in recent years by this method have more than justified the procedure. As an alternative, wrapping the diseased bowel in omentum after freeing adhesions will give good results. When serious complications, such as local abscess, perforation into the bladder, or general peritonitis have already occurred colostomy is the only justifiable procedure.

# GLYCOSURIA IN ACROMEGALY.

BY K. S. HETZEL, M.B., B.S. ADELAIDE,
M.R.C.P. LOND.,
ASSISTANT IN THE MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL.

GLYCOSURIA occurs in about 10 to 15 per cent. of acromegalics. Its exact relationship to pituitary disease is still in doubt. Ellis[1] has reported a case in which surgical removal of a pituitary tumour in an acromegalic was followed by improvement in carbohydrate metabolism. He has reviewed the current theories to account for the failure in carbohydrate metabolism, and, to fit the reported case, has supplied one of his own—that the glycosuria is related to excessive function of the intermediate lobe.

That there is some relationship between pituitary secretion and carbohydrate metabolism is undoubted, yet we must be mindful of the possibility that the glycosuria in acromegaly may be in some cases an independent condition, an essential diabetes. The question can hardly be settled by the experience of one clinician because acromegaly is relatively a rare disease, and therefore it seems desirable that the following single case be recorded as a help towards the accumulation of the necessary clinical data.

### *Report of Case.*

A. T., male, single, aged 54, was admitted to University College Hospital on Oct. 21st, 1924. He had lived in the Argentine for 25 years. At the age of 16 enlargement of the hands, face, and jaw began, and had progressed for about five years, since when the condition had been stationary. Frequency of micturition, thirst, and debility had been present for the last three and a half years. Ten months before admission to this hospital diplopia had developed, and while in hospital in Buenos Ayres for this he had been treated for his glycosuria by dieting. Insulin was also tried, but it was said to have been without effect, and the efficacy of the insulin was doubtful. He had typhoid fever at 26 years of age. A sister had had glycosuria for three years when young but this had disappeared later. His weight had been 12 st. 9 lb. (80 kilos) for years and his height 5 ft. 10 in. since young manhood.

*Condition on Admission.*—Weight 11 st. 12½ lb. Systolic blood pressure 110–120 mm. Hg; temperature, 98° F.; pulse, 80.

The patient had the appearance of a typical acromegalic. hands showed splaying out with square cut ends of the terminal phalanges. Voice deep and resonant. The tongue was large and fissured, and the lower jaw massive. Enlargement of the feet was present, but much less than that of the hands. Kyphosis was marked. X ray showed the sella turcica to be enlarged. The visual fields were normal. On ordinary ward diet the urine contained 0·6 per cent. of glucose, 230 g. in the 24 hours, with a large quantity of ketones. The glycosuria persisted after four days' starvation, only fluids being permitted, and the urine still contained 1·2 per cent. of glucose. The blood-sugar at the end of this time was 0·26 per cent. A glucose-tolerance test showed a diabetic curve. One hour and 50 minutes after ingestion of 50 g. of glucose the blood-sugar was 0·375 per cent. (its highest point), and at the end of three hours the blood-sugar was still 0·31 per cent. During the three hours 9·3 g. of glucose were excreted in the urine.

The patient was then given a diet of C. 33, P. 48, F. 77, calories 990, and the glycosuria continued for the next three days. The quantity of urine was now less than 1500 c.cm. in the 24 hours and the glucose excretion was 15 g. Insulin was then given, starting with 5 units twice a day and increasing to 10 units twice a day when the glycosuria disappeared. The diet was increased to 1555 calories (C. 39, P. 55, F. 131) and then again in two stages to 1960 calories (C. 57, P. 58, F. 167), and the insulin raised to 30 units a day in two doses given night and morning. The blood-sugar four and a half hours after breakfast and five hours after insulin was 0·24 per cent.—the urine being sugar-free with a trace of ketones.

The insulin was increased successively to 40, 45, 50, 55, and 60 units a day to lower this hyperglycæmia but the effect was only small, for the blood-sugar fluctuated throughout the day between 0·15 per cent. and 0·20 per cent., and the morning fasting blood-sugar was 0·22 per cent., so that an increase of 30 units of insulin had had only a small effect on the blood-sugar. After five and a half weeks' treatment his weight was 12 st. 1 lb., and his general condition was much improved when he was discharged from hospital.

Ten weeks later, Feb. 14th, 1925, he reported again. He had to reduce the insulin by 5 units in the evening because of the occurrence of symptoms of hypoglycæmia. His blood-sugar two and a half hours after breakfast and three hours after 30 units of insulin was 0·095 per cent., and two hours later 0·080 per cent. The recovery from the diabetic state continued and the patient never again had glycosuria. Two months later the insulin was reduced further to two doses of 20 units each. In November, 1925, he had an attack of "influenza" and was in bed for a week. Dyspnœa and œdema then developed, and a month later he was admitted to another hospital where he died in a week. During the last week before admission he had cut all carbohydrates out of his dietary, taken no insulin at all, and yet remained sugar-free. In hospital his urine was found to contain a trace of albumin but no blood or sugar. His systolic blood pressure was 170 mm. during an attack of dyspnœa but fell to 140 later. He was regarded as showing cardiac failure, and died in a sudden attack of dyspnœa with cyanosis. There was no bronchitis.

*Post-mortem Examination.*—A necropsy was not granted until 40 hours after death, and the organs were obtained by the courteous interest of Dr. Frank Deas. The pituitary was very large, but not cystic, and with no malignant extension. The lungs showed no naked-eye evidence of inflammation. The heart was hypertrophied, weighing 25½ oz. There was some atheroma of the mitral valves, and much more severe degeneration in the mesenteric vessels. The abdominal viscera did not show conspicuously the splanchnomegaly that may occur in acromegaly. The kidneys weighed 8 oz. each, and were slightly granular with small cysts, the general changes being arterio-sclerotic. The pancreas was large. Microscopically there were no serious pathological changes in either kidney or pancreas, after making allowance for post-mortem alterations. The atheroma of the intermediate or larger arteries had not led to much atrophy in the organs supplied by them.

### *Commentary.*

The glycosuria in this patient was probably independent, for the acromegaly had been stationary for over 33 years and the glycosuria had developed only in the last three to four years. The glycosuria was identical with that of diabetes, it reacted similarly to insulin and control of the diet. It was severe, starvation for four days before the use of insulin failed to control it; and the renal threshold to glucose was higher than normal (between 0 21 and 0·25 per cent.).

But there is an undoubted relationship between renal function and pituitary secretion. It is possible, though not proven, that from an excessive pituitary secretion in acromegaly an elevation of the renal threshold for glucose might occur from direct action on the kidney. Moreover, it is now established that pituitary secretion and insulin are antagonistic, so that from an excessive pituitary secretion neutralising insulin a condition of hyperglycæmia might arise and because of the elevation of the renal threshold the hyperglycæmia would not produce glycosuria. Thus a condition of persistent hyperglycæmia would occur and the long-continued strain on the islets of Langerhans due to the stimulus of excessive sugar in the blood would result in damage to them and failure in production of insulin with consequent glycosuria and diabetes mellitus. In this way the above case could be brought into line with a pituitary origin for the glycosuria, the ultimate failure of the islets not having occurred until 30 or more years after the onset of hyperpituitarism. It is noteworthy that the diabetic tendency lessened as the result of treatment with insulin and strict control of the diet, and that the necropsy did not reveal positive evidence of such disease in the pancreas as would have made it certain that the diabetes was of pancreatic origin

# Medical Societies.

## MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society held on Feb. 22nd, with Sir HOLBURT WARING, the President, in the chair, Sir HUMPHRY ROLLESTON introduced a discussion on the

### ÆTIOLOGY AND DIAGNOSIS OF GALL-STONES.

It was difficult, he said, to separate the closely allied subjects of gall-stones and inflammation of the gall-bladder, especially in the matter of diagnosis. Cholelithiasis occurred most frequently in "fat, flatulent, fertile females over 40," among the reasons for this being pregnancy, disordered metabolism leading to increased cholesterol content, the risk of puerperal infection, and sedentary habits. The two immediate causes of gall-stone formation were infection of the biliary passages and that disorder of the metabolism of fats which brought about an excess of cholesterol in the blood, and therefore in the bile. Sir Humphry Rolleston discussed the probable mechanism of these. A non hæmolytic streptococcus was believed by some to be a more important cause of cholecystitis than *B. coli*, but numerous others gave the latter a *prime* place. It might be a sequel of typhoid fever, even many years after the fever. The view that appendicitis might be secondary to cholecystitis had received but little support. Of 111 cases of gall-stones, Soper ascribed 106 to diseases of the colon. Excess of cholesterol in the blood (the normal being 0·16 per cent.) McNee showed was accompanied by increase in the bile The metabolic and infective factors in the production of cholecystitis were often combined. There were many cases of very chronic cholecystitis without cholelithiasis, and these would probably so greatly benefit by medical treatment that the more serious sequel would not arise.

In a summary of probable mechanisms in the formation of calculi Sir Humphry Rolleston said that pure cholesterol calculi were formed aseptically and without causal inflammation in a healthy gall-bladder, as a result of a metabolic excess of cholesterol in blood and bile. They might remain latent, or might lead to the common mixed calculi which were favoured by the excess of cholesterol in blood and bile. Small pigment calculi, formed of bilirubin and calcium carbonate, probably formed apart from infection, though were frequently determined by it.

With regard to disposing factors, pregnancy was an important one; gall-stones were ten times commoner in fertile than in sterile women. Stagnation of bile was said to favour their formation. Another factor was over-eating, probably by increasing the available cholesterol. The war privations in Russia showed in the Leningrad Hospital a drop in these diseases from 4·7 per cent. (1916) to 0·8 per cent. (1919). Heredity also played some part, in the direction of a defective metabolism. And arterio-sclerosis and chronic renal disease also increased the cholesterol content of the blood

In the matter of diagnosis—a very large subject—he proposed only to raise a few points. Clinically, the symptoms need to be considered according to their position—i.e., whether in the gall-bladder, the cystic duct, the common bile-duct, the ampulla of Vater, or in the intestine producing obstruction there. These he considered in some detail. When a calculus emigrated out of the gall-bladder it began to cause symptoms more referable to irritation of the biliary tract. He mentioned aberrant forms and the conditions the symptoms simulated. When the calculus passed into the common or other bile-ducts jaundice occurred. Among 1000 operations on the gall-bladder and biliary tract, Truesdale found 75 cases of obstruction of the common bile-duct; and of these, 37 were due to gall-stones, 14 to acute, 16 to chronic pancreatitis. All the pancreatitic cases had gall-stones. Pancreatitis was very likely to ensue from a calculus in the ampulla of Vater.

He regarded X ray examinations in these cases as of rapidly increasing value. The direct method, which showed the stones directly on the plate in 50 per cent., was being improved by inflation of the abdominal cavity with oxygen But the intravenous injection of tetrabromphenolphthalein was prone to give severe reactions, though tetraiodophenolphthalein was less toxic and could be given in pill form. Indirect evidence of gall-bladder disease was distortion of the pyloric region of the stomach, the duodenal cap, or the hepatic flexure of the colon by the traction of adhesions, or by pressure exerted by a large gall-bladder.

Laboratory tests were less decisive in the diagnosis of gall-stones than in that of many other conditions, and at best only provided one of several factors to be considered. Cammidge's tests of urine and fæces had now fallen out of favour, but the speaker said that he had for years experienced much help from Cammidge's reports as to the diagnosis of doubtful cases of jaundice which might be due either to gall-stones, pancreatitis, or new growth.

*The Surgical Aspect.*

Mr. R. P. ROWLANDS presented the subject from the surgical side. He said that most reliance at present could be placed on a painstaking study of the clinical symptoms and the ordinary physical signs. Still, every source of information should be tapped and used as a help in diagnosis. Except in really urgent cases, much was to be said in favour of a careful routine examination. Gall-stones were often distinguishable from other conditions by the long duration and the recurrent character of the symptoms which might follow pregnancy or enteric, chiefly in fat, middle-aged women. The symptoms of gall stones were more vague and capricious than those of duodenal ulcer, and they gave a tenderness on deep percussion higher up and further out. Hyperchlorhydria was only occasionally associated with gall-stones, but was almost constant in duodenal ulcer. X ray examination was important in excluding such diseases as duodenal ulcer and cancer of the stomach, but he did not regard it as so important as Sir Humphry Rolleston suggested. Examination of the duodenal bile was a very valuable method, as it often showed pus, or crystals, or an excess of mucus. Cancer of the stomach sometimes presented considerable difficulties, especially when achlorhydria was discovered. But its deficiency might be accidental and have no relation to cancer. The fever of cholangitis had been mistaken for malaria, but should not have been if a blood examination had been made. He had known a blood-clot cause severe colic by blocking the common bile-duct; the lady died from hæmorrhage which had originated in an ulcer general peritonitis. He was not operated upon till four days after the perforation, but recovered with free drainage and was quite well five years later.

### *Summary.*

Diverticulitis is a condition which, if detected in its early stages and properly treated, may be so kept in check that surgical interference will not be necessary, or may be much delayed. In its fully developed condition it is a very grave disease with most serious possibilities, and surgical interference is indicated before the more serious complications have taken place.

Operations for diverticulitis are both difficult and dangerous. Interference with the diseased bowel may easily set up grave sepsis or result in a fæcal fistula, and great care and judgment is necessary. Colostomy well away from the trouble is the safest procedure and should not be dangerous if the diseased bowel is not too thoroughly explored, or not explored at all.

Resection with end-to-end anastomosis and temporary cæcostomy is the ideal treatment, and the results I have obtained in recent years by this method have more than justified the procedure. As an alternative, wrapping the diseased bowel in omentum after freeing adhesions will give good results. When serious complications, such as local abscess, perforation into the bladder, or general peritonitis have already occurred colostomy is the only justifiable procedure.

# GLYCOSURIA IN ACROMEGALY.

By K. S. HETZEL, M.B., B.S. Adelaide, M.R.C.P. Lond.,

ASSISTANT IN THE MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL.

Glycosuria occurs in about 10 to 15 per cent. of acromegalics. Its exact relationship to pituitary disease is still in doubt. Ellis [1] has reported a case in which surgical removal of a pituitary tumour in an acromegalic was followed by improvement in carbohydrate metabolism. He has reviewed the current theories to account for the failure in carbohydrate metabolism, and, to fit the reported case, has supplied one of his own—that the glycosuria is related to excessive function of the intermediate lobe.

That there is some relationship between pituitary secretion and carbohydrate metabolism is undoubted, yet we must be mindful of the possibility that the glycosuria in acromegaly may be in some cases an independent condition, an essential diabetes. The question can hardly be settled by the experience of one clinician because acromegaly is relatively a rare disease, and therefore it seems desirable that the following single case be recorded as a help towards the accumulation of the necessary clinical data.

### *Report of Case.*

A. T., male, single, aged 54, was admitted to University College Hospital on Oct. 21st, 1924. He had lived in the Argentine for 25 years. At the age of 16 enlargement of the hands, face, and jaw began, and had progressed for about five years, since when the condition had been stationary. Frequency of micturition, thirst, and debility had been present for the last three and a half years. Ten months before admission to this hospital diplopia had developed, and while in hospital in Buenos Ayres for this he had been treated for his glycosuria by dieting. Insulin was also tried, but it was said to have been without effect, and the efficacy of the insulin was doubtful. He had typhoid fever at 26 years of age. A sister had had glycosuria for three years when young but this had disappeared later. His weight had been 12 st. 9 lb. (80 kilos) for years and his height 5 ft. 10 in. since young manhood.

*Condition on Admission.*—Weight 11 st. 12¼ lb. Systolic blood pressure 110–120 mm. Hg; temperature, 98° F.; pulse, 80.

The patient had the appearance of a typical acromegalic. The hands showed splaying out with square cut ends of the terminal phalanges. Voice deep and resonant. The tongue was large and fissured, and the lower jaw massive. Enlargement of the feet was present, but much less than that of the hands. Kyphosis was marked. X ray showed the sella turcica to be enlarged. The visual fields were normal. On ordinary ward diet the urine contained 6·6 per cent. of glucose, 230 g. in the 24 hours, with a large quantity of ketones. The glycosuria persisted after four days' starvation, only fluids being permitted, and the urine still contained 1·2 per cent. of glucose. The blood-sugar at the end of this time was 0·26 per cent. A glucose-tolerance test showed a diabetic curve. One hour and 50 minutes after ingestion of 50 g. of glucose the blood-sugar was 0·375 per cent. (its highest point), and at the end of three hours the blood-sugar was still 0·31 per cent. During the three hours 9·3 g. of glucose were excreted in the urine.

The patient was then given a diet of C. 33, P. 48, F. 77, calories 990, and the glycosuria continued for the next three days. The quantity of urine was now less than 1500 c.cm. in the 24 hours and the glucose excretion was 15 g. Insulin was then given, starting with 5 units twice a day and increasing to 10 units twice a day when the glycosuria disappeared. The diet was increased to 1555 calories (C. 39, P. 55, F. 131) and then again in two stages to 1960 calories (C. 57, P. 58, F. 167), and the insulin raised to 30 units a day in two doses given night and morning. The blood-sugar four and a half hours after breakfast and five hours after insulin was 0·24 per cent.—the urine being sugar-free with a trace of ketones.

The insulin was increased successively to 40, 45, 50, 55, and 60 units a day to lower this hyperglycæmia but the effect was only small, for the blood-sugar fluctuated throughout the day between 0·15 per cent. and 0·20 per cent., and the morning fasting blood-sugar was 0·22 per cent., so that an increase of 30 units of insulin had had only a small effect on the blood-sugar. After five and a half weeks' treatment his weight was 12 st. 1 lb., and his general condition was much improved when he was discharged from hospital.

Ten weeks later, Feb. 14th, 1925, he reported again. He had to reduce the insulin by 5 units in the evening because of the occurrence of symptoms of hypoglycæmia. His blood-sugar two and a half hours after breakfast and three hours after 30 units of insulin was 0·095 per cent., and two hours later 0·080 per cent. The recovery from the diabetic state continued and the patient never again had glycosuria. Two months later the insulin was reduced further to two doses of 20 units each. In November, 1925, he had an attack of "influenza" and was in bed for a week. Dyspnœa and œdema then developed, and a month later he was admitted to another hospital where he died in a week. During the last week before admission he had cut all carbohydrates out of his dietary, taken no insulin at all, and yet remained sugar-free. In hospital his urine was found to contain a trace of albumin but no blood or sugar. His systolic blood pressure was 170 mm. during an attack of dyspnœa but fell to 140 later. He was regarded as showing cardiac failure, and died in a sudden attack of dyspnœa with cyanosis. There was no bronchitis.

*Post-mortem Examination.*—A necropsy was not granted until 40 hours after death, and the organs were obtained by the courteous interest of Dr. Frank Deas. The pituitary was very large, but not cystic, and with no malignant extension. The lungs showed no naked-eye evidence of inflammation. The heart was hypertrophied, weighing 25¼ oz. There was some atheroma of the mitral valves, and much more severe degeneration in the mesenteric vessels. The abdominal viscera did not show conspicuously the splanchnomegaly that may occur in acromegaly. The kidneys weighed 8 oz. each, and were slightly granular with small cysts, the general changes being arterio-sclerotic. The pancreas was large. Microscopically there were no serious pathological changes in either kidney or pancreas, after making allowance for post-mortem alterations. The atheroma of the intermediate or larger arteries had not led to much atrophy in the organs supplied by them.

### *Commentary.*

The glycosuria in this patient was probably independent, for the acromegaly had been stationary for over 33 years and the glycosuria had developed only in the last three to four years. The glycosuria was identical with that of diabetes, it reacted similarly to insulin and control of the diet. It was severe, starvation for four days before the use of insulin failed to control it; and the renal threshold to glucose was higher than normal (between 0·21 and 0·25 per cent.).

But there is an undoubted relationship between renal function and pituitary secretion. It is possible, though not proven, that from an excessive pituitary secretion in acromegaly an elevation of the renal threshold for glucose might occur from direct action on the kidney. Moreover, it is now established that pituitary secretion and insulin are antagonistic, so that from an excessive pituitary secretion neutralising insulin a condition of hyperglycæmia might arise and because of the elevation of the renal threshold the hyperglycæmia would not produce glycosuria. Thus a condition of persistent hyperglycæmia would occur and the long-continued strain on the islets of Langerhans due to the stimulus of excessive sugar in the blood would result in damage to them and failure in production of insulin with consequent glycosuria and diabetes mellitus. In this way the above case could be brought into line with a pituitary origin for the glycosuria, the ultimate failure of the islets not having occurred until 30 or more years after the onset of hyperpituitarism. It is noteworthy that the diabetic tendency lessened as the result of treatment with insulin and strict control of the diet, and that the necropsy did not reveal positive evidence of such disease in the pancreas as would have made it certain that the diabetes was of pancreatic origin.

AT a meeting of this Society held on Feb. 22nd, with Sir HOLBURT WARING, the President, in the chair, Sir HUMPHRY ROLLESTON introduced a discussion on the

### ÆTIOLOGY AND DIAGNOSIS OF GALL-STONES.

It was difficult, he said, to separate the closely allied subjects of gall-stones and inflammation of the gall-bladder, especially in the matter of diagnosis. Cholelithiasis occurred most frequently in "fat, flatulent, fertile females over 40," among the reasons for this being pregnancy, disordered metabolism leading to increased cholesterol content, the risk of puerperal infection, and sedentary habits. The two immediate causes of gall-stone formation were infection of the biliary passages and that disorder of the metabolism of fats which brought about an excess of cholesterol in the blood, and therefore in the bile. Sir Humphry Rolleston discussed the probable mechanism of these. A non-hæmolytic streptococcus was believed by some to be a more important cause of cholecystitis than *B. coli*, but numerous others gave the latter a prime place. It might be a sequel of typhoid fever, even many years after the fever. The view that appendicitis might be secondary to cholecystitis had received but little support. Of 411 cases of gall-stones, Soper ascribed 106 to diseases of the colon. Excess of cholesterol in the blood (the normal being 0·16 per cent.) McNee showed was accompanied by increase in the bile. The metabolic and infective factors in the production of cholecystitis were often combined. There were many cases of very chronic cholecystitis without cholelithiasis, and these would probably so greatly benefit by medical treatment that the more serious sequel would not arise.

In a summary of probable mechanisms in the formation of calculi Sir Humphry Rolleston said that pure cholesterol calculi were formed aseptically and without causal inflammation in a healthy gall-bladder, as a result of a metabolic excess of cholesterol in blood and bile. They might remain latent, or might lead to the common mixed calculi which were favoured by the excess of cholesterol in blood and bile. Small pigment calculi, formed of bilirubin and calcium carbonate, probably formed apart from infection, though were frequently determined by it.

With regard to disposing factors, pregnancy was an important one; gall-stones were ten times commoner in fertile than in sterile women. Stagnation of bile was said to favour their formation. Another factor was over-eating, probably by increasing the available cholesterol. The war privations in Russia showed in the Leningrad Hospital a drop in these diseases from 4·7 per cent. (1916) to 0·8 per cent. (1919). Heredity also played some part, in the direction of a defective metabolism. And arterio-sclerosis and chronic renal disease also increased the cholesterol content of the blood.

In the matter of diagnosis—a very large subject—he proposed only to raise a few points. Clinically, the symptoms need to be considered according to their position—i.e., whether in the gall-bladder, the cystic duct, the common bile-duct, the ampulla of Vater, or in the intestine producing obstruction there. These he considered in some detail. When a calculus emigrated out of the gall-bladder it began to cause symptoms more referable to irritation of the biliary tract. He mentioned aberrant forms and the conditions the symptoms simulated. When the calculus passed into the common or other bile-ducts jaundice occurred. Among 1000 operations on the gall-bladder and biliary tract, Truesdale found 76 cases of obstruction of the common bile-duct; and of these, 37 were due to gall-stones, 14 to acute, 16 to chronic pancreatitis. All the pancreatitic cases had gall-stones. Pancreatitis was very likely to ensue from a calculus in the ampulla of Vater.

He regarded X ray examinations in these cases as of rapidly increasing value. The direct method, which showed the stones directly on the plate in 50 per cent., was being improved by inflation of the abdominal cavity with oxygen. But the intravenous injection of tetrabromphenolphthalein was prone to give severe reactions, though tetraiodophenolphthalein was less toxic and could be given in pill form. Indirect evidence of gall-bladder disease was distortion of the pyloric region of the stomach, the duodenal cap, or the hepatic flexure of the colon by the traction of adhesions, or by pressure exerted by a large gall-bladder.

Laboratory tests were less decisive in the diagnosis of gall-stones than in that of many other conditions, and at best only provided one of several factors to be considered. Cammidge's tests of urine and fæces had now fallen out of favour, but the speaker said that he had for years experienced much help from Cammidge's reports as to the diagnosis of doubtful cases of jaundice which might be due either to gall-stones, pancreatitis, or new growth.

### *The Surgical Aspect.*

Mr. R. P. ROWLANDS presented the subject from the surgical side. He said that most reliance at present could be placed on a painstaking study of the clinical symptoms and the ordinary physical signs. Still, every source of information should be tapped and used as a help in diagnosis. Except in really urgent cases, much was to be said in favour of a careful routine examination. Gall-stones were often distinguishable from other conditions by the long duration and the recurrent character of the symptoms which might follow pregnancy or enteric, chiefly in fat, middle-aged women. The symptoms of gall-stones were more vague and capricious than those of duodenal ulcer, and they gave a tenderness on deep percussion higher up and further out. Hyperchlorhydria was only occasionally associated with gall-stones, but was almost constant in duodenal ulcer. X ray examination was important in excluding such diseases as duodenal ulcer and cancer of the stomach, but he did not regard it as so important as Sir Humphry Rolleston suggested. Examination of the duodenal bile was a very valuable method, as it often showed pus, or crystals, or an excess of mucus. Cancer of the stomach sometimes presented considerable difficulties, especially when achlorhydria was discovered. But its deficiency might be accidental and have no relation to cancer. The fever of cholangitis had been mistaken for malaria, but should not have been if a blood examination had been made. He had known a blood-clot cause severe colic by blocking the common bile-duct; the lady died from hæmorrhage which had originated in an ulcer in the neck of the gall-bladder due to a stone having become impacted there. In half the cases of hæmolytic jaundice gall-stones were present, and in many the gall-stones were removed, but the jaundice was not cured until splenectomy had been done. He considered that intestinal obstruction was nearly always overlooked until it was too late. In cases of obscurity it was often wisest to open up and conduct an exploration. In ten gall-bladders which he had removed there was already carcinoma, and not one of the patients had yet had a recurrence, though one was removed 15 years ago.

### *The Radiological Aspect.*

Dr. **ROBERT KNOX** presented the radiological aspect of the subject, his contribution consisting chiefly of the epidiascopic demonstration of a remarkably instructive series of skiagrams of his own and Dr. Stewart's, of New York. He said the greatest advance in the delineation of the shadows in the deep regions under discussion followed the use of tetraiodophenolphthalein, and the oral administration of this he regarded as safe.

### *Discussion.*

Mr. **PATERSON ROSS** spoke favourably of the cholecystography method, and pointed out that the serious reactions following the oral method occurred in the early cases. The solution certainly became more toxic with keeping, even in ampoules, therefore it should be used very fresh.

Sir **CRISP ENGLISH** agreed with Sir Humphry Rolleston's disposing conditions tending to the production of gall-stones, and insisted that gall-stones were a very common condition. In 4300 post-mortem examinations he found 242 cases of gall-stones, or 5·7 per cent. A conclusion therefore was that they often occurred without causing symptoms. He agreed with Mr. Rowlands that the diagnosis of gall-stones was mainly a matter of hard clinical work; often careful watching would result in a correct diagnosis in a difficult case. He spoke highly of Dr. Knox's demonstration.

Dr. **RALPH KNOTT** said that after doing a series of 200 examinations of duodenal contents for diagnostic purposes in connexion with gall-bladder disease, the question arose whether it was worth while. If positive results were obtained they were useful, as the surgical findings accorded with them, but a negative report was of much less value. These tests, he thought, should be used when other evidence was either doubtful or conflicting.

Dr. **PARKES WEBER** discussed the question of hepatic efficiency in diagnosing cirrhosis of the liver differentially from cholelithiasis. In some cases a surgeon had operated when subacute hepatic atrophy was present, with the result that the anæsthetic caused a fatality. Hepatic efficiency tests should, he thought, be used by surgeons before operating.

Dr. **LENNOX WAINWRIGHT** pointed out that the injection salts for promoting clarity of radiographic pictures suffered from exposure to light, and would probably alter in character.

Sir **WILLIAM WILLCOX** uttered a note of warning concerning the intravenous injection of tetraiodophenolphthalein. He said the extra clearness of radiographic shadows of gall-stones was often due to the presence of traces of copper in them. He had also found minute traces of the same metal in fæces which he had examined. He agreed with Mr. Rowlands as to the great value of the clinical evidence of gall-stones. Also a four-hourly temperature observation was of use, as gall-stones usually produced a rise to 100° F., whereas renal conditions did not.

Dr. **KNYVETT GORDON** said he considered a careful histological examination of the blood was of some value in the diagnosis of gall-stones; there was nearly always an associated polymorphonuclear leucocytosis. The *B. coli* had much to do with these conditions, but not the ordinary strain, and he advocated the application of laboratory tests to the *B. coli* found in the stools. The diastatic content of the urine was also important in the diagnosis of malignant growth at the head of the pancreas; it was not increased in gall-stones or cholecystitis, but was in pancreatic disease.

The **PRESIDENT** spoke of the kind of case, of which he had seen several, where operation did not reveal gall-stones, but a very long gall-bladder hung down from the liver by a small attachment, and when it got twisted it caused attacks of pain closely resembling those of gall-stones. In some of these he had deliberately removed the gall-bladder and the patient had remained free from pain though the operation was done years ago. On more than one occasion, when patients had come under observation because of what was thought to be gall-stones, the urine had been found to have a considerable increase of diastase due to recurrent pancreatitis, and by treating the latter the trouble had been got over. Removal of carcinoma of the gall-bladder gave much better results in regard to freedom from recurrence than did operation on carcinoma elsewhere.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on Feb. 5th Mr. **A. L. WHITEHEAD**, the President, occupied the chair, and a paper by Prof. **J. W. MCLEOD** and Dr. **BERTHA WHEATLEY** was read, entitled

### *The Importance of Bacterial Hæmolysins in Pernicious Anæmia.*

The emphasis recently laid on the importance of achlorhydria in pernicious anæmia had awakened, they said, fresh interest in the bacterial hæmolysins as possible factors in the development of this disease; for an increased bacterial content of the upper bowel in achlorhydria had been accepted by all investigators. Their own observations had been made with the help of Dr. W. MacAdam in obtaining duodenal fluids by means of the Einhorn tube. Twelve cases of pernicious anæmia and several patients with normal or hyperchlorhydric gastric juice, as well as one or two achlorhydrias without anæmia, had been investigated. The general impression obtained by examining both fresh and heated blood-agar plates inoculated from these fluids was that in all achlorhydrias the duodenum contained large numbers of bacteria amongst which the pharyngeal and bowel types were fairly evenly represented.

It was noteworthy that no actively hæmolytic streptococcus had been isolated, although the common types of mouth streptococcus, which gave slight haloes of clearing on blood-agar plates, were usually present. The two hæmolytic bacteria found were the hæmolytic hæmoglobinphilic bacterium of Pritchett and Stillman and *B. welchii*. The first had been found more often, but *B. welchii* produced a more powerful hæmolysin. Prof. Adrian Stokes in this country, and Moench, Kahn and Torrey [1] in America had recently drawn attention to the markedly increased content of *B. welchii* in the fæces in pernicious anæmia. Unless a specific parasite responsible both for the achlorhydria and the anæmia existed, it seemed likely that *B. welchii* played the chief rôle in producing anæmia when once the bowel and throat bacteria had invaded the jejunum and duodenum. Difficulties, however, existed in regard to the rôle of *B. welchii*, since it had been found, by Kahn and Torrey and by Cornell, that injections of Welch toxin induced an increase in the polymorphonuclear leucocytes, and also, after a short time, immunity.

Dr. **J. GORDON** read a paper on the

### *Influence of Amino-Acids on Bacterial Growth.*

Fourteen different amino-acids, he said, had been investigated separately with reference to their effect on the growth of bacteria in concentrations from 0·1 per cent. to 1·0 per cent. in 1·0 per cent. peptone broth. No marked effect had been observed on the growth of bacteria, such as *B. coli* and staphylococcus, which constantly grow freely in peptone broth. Such of the more delicately-growing bacteria as were tested had been distinctly influenced by some amino-acids, and by this criterion the amino-acids might be divided into three groups: (a) *Indifferent:* arginine, glutamic acid, histidine, leucine, lysine, tyrosine, and valine; (b) *favouring:* taurine, aspartic acid, and alanine; and (c) *inhibitory:* cystine, glycine, phenylalanine, and tryptophane. In the absence of serum or blood, media with a basis of tryptic digest were inferior to peptone broth for growing delicate bacteria; such media could be improved if a considerable part of the amino-acid was removed by butyl alcohol extraction.

[1] Journal of Infectious Diseases, 1925, xxxvii., 162.

### *Demonstration of Specimens.*

Dr. H. H. MOLL (Leeds), in association with Dr. O. W. VINING, showed an example of a Meckel's diverticulum 2 ft. 0¼ in. long. The diverticulum had become dislocated from its normal anatomical relationship to the small intestine and ran parallel to it for the whole of its course, and was also firmly and physiologically adherent to it. The whole specimen had the appearance of several feet of double intestine. Dr. Moll had been unable to find a similar case in the literature He showed a diagram indicating the way in which, in his opinion, the diverticulum had been dislocated from the antimesenteric border of the small intestine.

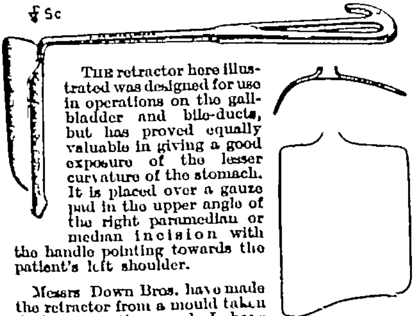
Mr. CARLTON OLDFIELD described a case of ovarian pregnancy and demonstrated the specimen. He reviewed the whole subject of extra-uterine gestation and gave an historical account of its place in obstetrics since the time of Lawson Tait.

Dr. MAXWELL TELLING, Mr. J. A. COUPLAND, and Dr. E. O. CROFT also contributed to the discussion.

Other specimens were shown by Dr. T. H. L. BEDFORD, Dr. A. L. TAYLOR, Mr. A. RICHARDSON, Mr. G. SYMONS, and Dr. VINING, and Dr. F S. FOWWEATHER made Some Remarks on Osteomalacia with special reference to a recent case.

# New Inventions.

## AN IMPROVED RETRACTOR.



THE retractor here illustrated was designed for use in operations on the gall-bladder and bile-ducts, but has proved equally valuable in giving a good exposure of the lesser curvature of the stomach. It is placed over a gauze pad in the upper angle of the right paramedian or median incision with the handle pointing towards the patient's left shoulder.

Messrs Down Bros. have made the retractor from a mould taken during operation, and I have found it fulfils its purpose admirably.

HAROLD UPCOTT, F R C.S Eng.

KINGSTON-UPON-THAMES POOR LAW HOSPITAL.—The Kingston Guardians have decided by a large majority to proceed with their scheme for the enlargement of their hospital and the erection of a nurses' home at an estimated cost of £100,000 The opposition was based upon the possibility of boards of guardians shortly being abolished.

# Reviews and Notices of Books.

### THE THERAPY OF PUERPERAL FEVER.

By Privatdozent Dr. ROBERT KOEHLER, formerly Assistant of the Gynæcological Department of the Krankenhaus Wieden, Vienna. English edition prepared by HUGO EHRENFEST, M.D., F.A.C.S., Associate in Obstetrics, Washington University School of Medicine. London: Henry Kimpton. 1926. With 27 illustrations. Pp. 276. 18s.

IN the preface to the American edition of this monograph Dr. Ehrenfest states that to his knowledge no work dealing specifically with the problem of puerperal infection has been presented to English-speaking physicians within the last 15 years. It was for this reason that he decided to translate Dr. Koehler's book. The translation appears at an opportune moment, when the inefficacy of many of the therapeutic measures formerly advocated has been only too well demonstrated. Quite recently newer methods, such as chemotherapy and non-specific protein therapy, have figured largely in the treatment of puerperal infections and the author here attempts to assess their true value. At the clinic of Prof. Josef Halban in Vienna, Dr. Koehler has had abundant material and ample means of testing these and other remedies. This investigation he has fully recorded, giving the results of his own experience with each and illustrating important facts by quoting the clinical histories of typical cases. Post-mortem examinations were made on the majority of fatal cases. Animal experiments were not carried out, as the author was convinced that the exact mode of infection that in a woman leads to puerperal fever could not be produced in the lower species; therefore, therapeutic success in the laboratory with any given remedy left the clinician unconvinced.

The book is divided into two parts. Part 1 deals briefly with the prophylactic measures taken to prevent infection, amongst which the method of rectal examination is considered important. The routine use of preliminary lactic acid douches and prophylactic immunisation with vaccines and sera are not favoured Part 2 deals with therapy, and concludes with an extensive bibliography of 20 pages. Innumerable curative measures are here discussed. A few of the more important ones may be referred to The author repudiates the doctrine of the activists and deals conservatively with the post-partum uterus On principle he refrains from instrumentation in the presence of puerperal infection, breaking this routine only in cases where an excessive hæmorrhage caused by placental rests could not be controlled by tight packing of the uterus. He wholly condemns the operation for ligation of veins, and bases his opinion not only on a careful study of necropsy findings but also on the difficulty of diagnosing the extent of the thrombosis and the existence of a concomitant lymphangitis. In his hands curative methods based on the introduction of antiseptics, foreign proteins, or sera into the blood have so far proved inefficient. Actual cure by milk injections was not observed in a single case and this form of treatment was discontinued some years ago. The results of treatment with vaccines, and especially with heterovaccines, compare well with any method of treatment so far suggested, but Dr. Koehler is of the opinion that a rational therapy of puerperal fever is still to seek.

The book is a scientific and masterly treatise.

### MALIGNANCY AND EVOLUTION.

By MORLEY ROBERTS. London: Eveleigh Nash and Grayson. 1925. Pp. 310. 18s.

AS far as can be discerned among the mass—or perhaps rather volume—of words with which it is overlaid, the author's thesis seems to be that cancer is a "hostile symbiosis" of the same nature as organs show in individual development and in evolution. A tumour may in this way be a tentative organ which has somehow been able to evade the normal cooperative control of the body; it may succeed in the individual and kill him, or it may succeed phylogenetically and make a new gland. In one point this view has much to commend it, for it regards tumour formation as an almost normal process and therefore in posing the question of the cause of cancer it asks: Why does not everybody have cancer? instead of the customary, Why do some people have cancer? It gives, that is, particular attention to the mechanism which prevents all epithelia from growing cancers. How far the author succeeds in establishing his hypotheses must be left to those who have the leisure to read his book. His whole idea of the relationships of the different parts of the body being one of hostility rather than of cooperation is probably wrong, and his analogy between the organism and a human society mistaken. But hardened professionals will needs be interested to see how some of their facts strike an astute and studious layman and what he adds them up to. Mr. Roberts, for instance, appreciates that splenomegalic polycythæmia is a tumour; he puts a juster value on the work of Gye and Barnard than some people have done; and he sums up the ways of science and the probable value of outside interference very well when he says: "It is hard to persuade the zealous and brilliant experimentalist that a week of reading and contemplation of other work may give greater results than a month or even a year in a laboratory, while those who might utilise the labour of others too frequently lack the scientific armament which would enable them to undertake such a task." And those who have patience will find many such spots on which Mr. Roberts has put an interesting finger.

### A TEXT-BOOK OF MEDICAL DIAGNOSIS.

Third edition. By JAMES M. ANDERS, M.D., Ph.D., Professor of Medicine, Medico-Chirurgical College Graduate School of Medicine, University of Pennsylvania; and L. NAPOLEON BOSTON, A.M., M.D., Associate Professor of Medicine, Graduate School of Medicine, University of Pennsylvania. London and Philadelphia: W. B. Saunders Company. Pp. 1422. 55*s.*

THE authors have attempted to produce in one volume a reliable aid to the diagnosis of medical diseases for the general practitioner and student. Diagnostic aspects of each complaint are discussed more exhaustively than is possible in text-books of medicine. The general plan of the second edition has been retained and recent advances have been added.

As a book of reference it is well arranged. The index is good and the subheadings make for rapid work. The pathological definitions of each disease give a clear conception based on its morbid anatomy. The value of this method of approach is emphasised by the authors; its advantage is seen specially in the description of syphilis of the central nervous system and disseminated sclerosis, conditions in which the great variety of symptoms and signs at onset depend on the part of the nervous system first attacked. The separate headings at the end of each section for laboratory diagnosis and summary of diagnosis are valuable and the tables of differential diagnosis, of which there are many, are a useful addition. Clinical methods of investigation are explained fully at the beginning of each system. These are illustrated with diagrams of surface markings and photographs of actual methods of examination. Laboratory methods of use in diagnosis are described; X ray methods are dealt with in special sections and well illustrated. In some instances diseases attacking children as well as adults are treated separately. The space available for this purpose is necessarily limited, but a special tion on the diagnosis of rheumatism in children ight well have been included. The cinematograph ustrations do not give a very clear idea of the abnormalities of gait they represent and a single picture showing the characteristic posture in such cases would probably be more helpful. Apart from this the illustrations are of outstanding merit.

The value of a text-book of diagnosis depends largely on the accuracy of emphasis laid on each symptom, sign, and investigation described. Only by a true knowledge of these proportionate values can a high standard of diagnostic accuracy be maintained, and needless research, often worrying to the patient, be avoided. In this respect the authors have succeeded as far as is possible in a book containing a great amount of information.

### A MANUAL OF HYGIENE AND PUBLIC HEALTH.

By JAHAR LAL DAS, D.P.H., Officiating Assistant Director of Public Health, Bihar and Orissa. Calcutta: Butterworth and Co. (India), Ltd. 1925. Pp. 634. 10*s.* 6*d.*

THE subtitle of this manual describes it as a textbook for medical and public health students, and it is obviously meant for those who intend to practise in tropical countries. It has much in common with the "Treatise on Hygiene and Public Health," in the writing of which the author collaborated with Dr. B. N. Ghosh, but important new matter has been added.

The book deals in 28 chapters with most of the subjects of importance to the sanitarian in all countries—e.g., vital statistics, climate and meteorology, ventilation, water-supplies, soil, housing, food, refuse and sewage disposal, disposal of the dead, sanitation of villages, fairs, festivals and camps, infection, insect carriers of disease, animal parasites, communicable diseases, personal and industrial hygiene, maternity and child welfare, school medical inspection, and popular education on health. Certain rules and orders in connexion with public health in force in Bihar and Orissa, or in the whole province of Bengal, are reproduced in six appendices. The effective way in which this wide range of material is brought within small compass leaves little scope for criticism. The sequence in which the subjects are taken is a little unusual. It would probably have been more in keeping with the order of ideas which a teacher of public health desires to convey to his students if each had been placed more or less in the order set out above.

Throughout the book mention is made of most of the modern work relating to hygiene, but the terminology is not always up to date. For instance, the term "ptomaine poisoning" is still used, and a bacillus causing food poisoning, presumably the *B. aertrycke*, is referred to under the older name of *B. suipestifer* and classified as one of the paratyphoid bacilli. The classification of rats, a matter of special importance in the East, is very lightly dismissed and the old family name *mus* is retained. References to the original monographs on which our knowledge of plague, epidemic goitre, the association of rickets, and the purdah system in India are founded might with advantage be added in a second edition. Moreover, Leonard Rogers's work on the treatment of leprosy, which is of preventive significance, and the forms of cancer associated with customs peculiar to the East should receive notice.

The discussion of many of the subjects touched upon is a little too elementary for the post-graduate student, and it would be unsafe to rely entirely on this book for the purpose of the diplomas of public health granted by examining bodies in this country. It is, however, well suited for the use of English-speaking Indian medical students and will be useful to young medical men in this country whose work is likely to lie in India or elsewhere in the East. The problems peculiar to these countries are constantly referred to in illustration of the principles of sanitation, and space is not wasted in any attempt to convey clinical or bacteriological knowledge which may have a bearing on hygiene but ought to be the subject of separate study.

### SURGERY.

*An Introduction to Surgery.* Second edition. By RUTHERFORD MORISON, M.D., F.R.C.S., M.A., D.C.L., LL.D., Emeritus Professor of Surgery, Durham University; and CHARLES F. M. SAINT, C.B.E., M.D., M.S., F.R.C.S., Professor of Surgery, Cape Town University. Bristol: John Wright and Sons, Ltd. 1925. Pp. 347. 15s.

IT is always difficult for the student beginning clinical work to discover any order in the seeming chaos of surgical knowledge. Indeed, so little is really known of disease that it is not yet possible to generalise very much or indeed to build up any logical science, stage by stage, as is possible in the more exact realms of knowledge which the student has studied in his preliminary courses. Prof. Morison has grasped the difficulties of the student and has made the path easier by pointing out how it is often possible to argue by analogy from one surgical condition, and predict the course of events in another apparently quite unrelated. Prof. Saint has been responsible for an added section in which the principles enunciated in the first edition are amplified and illustrated. No book could be read with more profit by the student new to clinical work, and this second edition will assuredly be welcomed by him.

*Surgery of the Stomach and Small Intestine.* By J. SHELTON HORSLEY, M.D., Attending Surgeon, St. Elizabeth's Hospital, Richmond, Va. London and New York: D. Appleton and Co. 1926. Pp. 325. 21s.

THIS monograph has one highly commendable feature; there is included a section of 36 pages on the physiology of the stomach and intestines. This gives us a clue to the author's work. His outlook is always physiological and his treatment is moulded by such considerations. Ethylene is adopted as the routine anæsthetic because it seems to affect cardiac activity less than any other known anæsthetic. Yet ether must be added at times to obtain relaxation. Nitrous oxide and oxygen for long operations is condemned. The advantages of some form of local anæsthesia are conceded, but its limitations are recognised. Under the surgery of gastric ulcer considerable prominence is given to the author's method of pyloroplasty, but the place of other operations is duly acknowledged and in this respect a well-balanced judgment is given. A meagre account only of gastro-jejunal ulcer appears, and very little guidance for the treatment of this distressing complication. Where the Billroth I. operation is performed the duodenum is sutured to the lesser curve extremity of the stomach lumen, a procedure which must restrict the applicability of the method. The surgery of the small intestine is represented almost solely by obstruction. It has been given less detailed consideration than diseases of the stomach. The chapter on diagnosis of gastric disorders by a collaborator of the author is only moderately good. It would be easy to point to other defects in the book, but the good points outweigh occasional failure to reach the high standard set by the better sections.

### HEALTH OF THE WORKERS.

By Sir THOMAS OLIVER. London: Faber and Gwyer, Ltd. 1925. Pp. 220. 2s. 6d.

THIS small volume is intended to meet the needs of all members of the community, not merely those of our professional colleagues. In size it is little more than a pocket-book; but the author has condensed into its ten chapters a vast amount of interesting and useful information. Throughout the modern view of industry is presented—viz., that occupation should be health-giving, and that no man's occupation should be a menace to his health or a risk to his life. How far industry falls short of this ideal is set forth, and how the ideal may be attained is pointed out. Sir Thomas Oliver has himself taken no small part in ameliorating the lot of the worker and in minimising many of the risks to which in the past he was exposed, particularly in regard to miners' phthisis and lead poisoning. Short but clear accounts are given of many different occupational diseases; the facts stated may generally be accepted as accurate.

We commend this book especially to panel practitioners working in industrial districts.

### THE ASSAYING OF BRABANTIUS AND OTHER VERSE.

By C. S. SHERRINGTON. London: Oxford University Press. 1925. Pp. 67. 4s. 6d.

Prof. Sherrington publishes a slender collection of verse much of which has already appeared in the *Oxford Magazine*. He uses in the small selection a good many metres with facility, showing command of vocabulary and simile; nor are the poems a direct reflection of the work of others, as must so often happen with the poet whose main work lies outside the strict business of literary construction and expression. On the contrary, in an austere and picturesque way he is quite original as well as often melodious. The little volume closes with a quintette of sonnets in which he shows himself able to write of large things within the limits so straitly laid down by the form, and one of these, entitled "Speech," is notable in this way. Prof. Sherrington takes his place rightly among a growing group of medical men who have turned to verse for the expression of their intimate thoughts.

### THE MOSQUITOES OF EGYPT.

By T. W. KIRKPATRICK, B.A., F.E.S., Senior Entomologist, Ministry of Agriculture, Egypt; Anti-Malaria Commission of the Egyptian Government. Cairo: Government Press. 1925. Pp. 224. Piastres 30.

THIS imposing memoir is a much more serious contribution to medical entomology than its title would leave one to believe. In scope it reaches far beyond the confines of the country with which it deals; not only are the anatomy, morphology, and habits of the imago, larva, and pupa accurately described, but the classification and the somewhat ponderous synonymy, which have burdened this branch of entomology, are, it is hoped, finally unravelled. In fact, we know of no other publication of its size which deals with the subject so exhaustively. The clearness of the type, the exact and beautifully executed line drawings (the work of Mr. Eugène Kassessinoff), which are grouped together for the most part in 24 plates forming an appendix to the volume, are specially to be commended. The arrangement of the subject-matter is logical and there is a complete index. We congratulate the author, the Ministry of Agriculture, and the Government Press of Cairo on producing such an excellent piece of work.

### MAISTRE WACE.

A Pioneer in Two Literatures. By J. H. PHILPOT, M.D. London: Methuen and Co., Ltd. 1925. Pp. 155. 7s. 6d.

Dr. Philpot, already known as a novelist under the name of Philip Lafargue, has here given us a charming little study of some of the work of a writer who is almost unknown except to specialists. Maistre Wace was an Anglo-Norman poet, born in Jersey in the first decade of the twelfth century, who wrote the Roman de Brut, a history of the British kings from the time of King Arthur, and as a continuation, the Roman de Rou—namely, the history of the Dukes of Normandy and the Norman Conquest. Wace is probably forgotten by most people as the author of the Roman de Brut, but not very long after his death the poem was expanded by Layamon into his Brut, one of the landmarks of English poetry. The Roman de Rou, however, about the time of Richard II., began to be forgotten, owing to Norman French becoming a dead language, and it was not until the seventeenth century that the antiquary Duchesne copied out the first part of the poem. It was not printed until 1827, when Mr. Pluquet issued an edition at Rouen, and 50 years later a German scholar, Dr. Andresen, issued an show in individual development and in evolution. A tumour may in this way be a tentative organ which has somehow been able to evade the normal coöperative control of the body; it may succeed in the individual and kill him, or it may succeed phylogenetically and make a new gland. In one point this view has much to commend it, for it regards tumour formation as an almost normal process and therefore in posing the question of the cause of cancer it asks: Why does not everybody have cancer? instead of the customary, Why do some people have cancer? It gives, that is, particular attention to the mechanism which prevents all epithelia from growing cancers. How far the author succeeds in establishing his hypotheses must be left to those who have the leisure to read his book. His whole idea of the relationships of the different parts of the body being one of hostility rather than of coöperation is probably wrong, and his analogy between the organism and a human society mistaken. But hardened professionals will needs be interested to see how some of their facts strike an astute and studious layman and what he adds them up to. Mr. Roberts, for instance, appreciates that splenomegalic polycythæmia is a tumour; he puts a juster value on the work of Gye and Barnard than some people have done; and he sums up the ways of science and the probable value of outside interference very well when he says: "It is hard to persuade the zealous and brilliant experimentalist that a week of reading and contemplation of other work may give greater results than a month or even a year in a laboratory, while those who might utilise the labour of others too frequently lack the scientific armament which would enable them to undertake such a task." And those who have patience will find many such spots on which Mr. Roberts has put an interesting finger.

---

### A TEXT-BOOK OF MEDICAL DIAGNOSIS.

Third edition. By JAMES M. ANDERS, M.D., Ph.D., Professor of Medicine, Medico-Chirurgical College Graduate School of Medicine, University of Pennsylvania; and L. NAPOLEON BOSTON, A.M., M.D., Associate Professor of Medicine, Graduate School of Medicine, University of Pennsylvania. London and Philadelphia: W. B. Saunders Company. Pp. 1422. 55*s.*

THE authors have attempted to produce in one volume a reliable aid to the diagnosis of medical diseases for the general practitioner and student. Diagnostic aspects of each complaint are discussed more exhaustively than is possible in text-books of medicine. The general plan of the second edition has been retained and recent advances have been added.

As a book of reference it is well arranged. The index is good and the subheadings make for rapid work. The pathological definitions of each disease give a clear conception based on its morbid anatomy. The value of this method of approach is emphasised by the authors; its advantage is seen specially in the description of syphilis of the central nervous system and disseminated sclerosis, conditions in which the great variety of symptoms and signs at onset depend on the part of the nervous system first attacked. The separate headings at the end of each section for laboratory diagnosis and summary of diagnosis are valuable and the tables of differential diagnosis, of which there are many, are a useful addition. Clinical methods of investigation are explained fully at the beginning of each system. These are illustrated with diagrams of surface markings and photographs of actual methods of examination. Laboratory methods of use in diagnosis are described; X ray methods are dealt with in special sections and well illustrated. In some instances diseases attacking children as well as adults are treated separately. The space available for this purpose is necessarily limited, but a special section on the diagnosis of rheumatism in children might well have been included. The cinematograph ustrations do not give a very clear idea of the abnormalities of gait they represent and a single picture showing the characteristic posture in such cases would probably be more helpful. Apart from this the illustrations are of outstanding merit.

The value of a text-book of diagnosis depends largely on the accuracy of emphasis laid on each symptom, sign, and investigation described. Only by a true knowledge of these proportionate values can a high standard of diagnostic accuracy be maintained, and needless research, often worrying to the patient, be avoided. In this respect the authors have succeeded as far as is possible in a book containing a great amount of information.

---

### A MANUAL OF HYGIENE AND PUBLIC HEALTH.

By JAHAR LAL DAS, D.P.H., Officiating Assistant Director of Public Health, Bihar and Orissa. Calcutta: Butterworth and Co. (India), Ltd. 1925. Pp. 634. 10*s.* 6*d.*

THE subtitle of this manual describes it as a textbook for medical and public health students, and it is obviously meant for those who intend to practise in tropical countries. It has much in common with the "Treatise on Hygiene and Public Health," in the writing of which the author collaborated with Dr. B. N. Ghosh, but important new matter has been added.

The book deals in 28 chapters with most of the subjects of importance to the sanitarian in all countries—e.g., vital statistics, climate and meteorology, ventilation, water-supplies, soil, housing, food, refuse and sewage disposal, disposal of the dead, sanitation of villages, fairs, festivals and camps, infection, insect carriers of disease, animal parasites, communicable diseases, personal and industrial hygiene, maternity and child welfare, school medical inspection, and popular education on health. Certain rules and orders in connexion with public health in force in Bihar and Orissa, or in the whole province of Bengal, are reproduced in six appendices. The effective way in which this wide range of material is brought within small compass leaves little scope for criticism. The sequence in which the subjects are taken is a little unusual. It would probably have been more in keeping with the order of ideas which a teacher of public health desires to convey to his students if each had been placed more or less in the order set out above.

Throughout the book mention is made of most of the modern work relating to hygiene, but the terminology is not always up to date. For instance, the term "ptomaine poisoning" is still used, and a bacillus causing food poisoning, presumably the *B. aertrycke*, is referred to under the older name of *B. suipestifer* and classified as one of the paratyphoid bacilli. The classification of rats, a matter of special importance in the East, is very lightly dismissed and the old family name *mus* is retained. References to the original monographs on which our knowledge of plague, epidemic goitre, the association of rickets, and the purdah system in India are founded might with advantage be added in a second edition. Moreover, Leonard Rogers's work on the treatment of leprosy, which is of preventive significance, and the forms of cancer associated with customs peculiar to the East should receive notice.

The discussion of many of the subjects touched upon is a little too elementary for the post-graduate student, and it would be unsafe to rely entirely on this book for the purpose of the diplomas of public health granted by examining bodies in this country. It is, however, well suited for the use of English-speaking Indian medical students and will be useful to young medical men in this country whose work is likely to lie in India or elsewhere in the East. The problems peculiar to these countries are constantly referred to in illustration of the principles of sanitation, and space is not wasted in any attempt to convey clinical or bacteriological knowledge which may have a bearing on hygiene but ought to be the subject of separate study.

### SURGERY.

*An Introduction to Surgery.* Second edition. By RUTHERFORD MORISON, M.D., F.R.C.S., M.A., D.C.L., LL.D., Emeritus Professor of Surgery, Durham University; and CHARLES F. M. SAINT, C.B.E., M.D., M.S., F.R.C.S., Professor of Surgery, Cape Town University. Bristol: John Wright and Sons, Ltd. 1925. Pp. 347. 15*s.*

IT is always difficult for the student beginning clinical work to discover any order in the seeming chaos of surgical knowledge. Indeed, so little is really known of disease that it is not yet possible to generalise very much or indeed to build up any logical science, stage by stage, as is possible in the more exact realms of knowledge which the student has studied in his preliminary courses. Prof. Morison has grasped the difficulties of the student and has made the path easier by pointing out how it is often possible to argue by analogy from one surgical condition, and predict the course of events in another apparently quite unrelated. Prof. Saint has been responsible for an added section in which the principles enunciated in the first edition are amplified and illustrated. No book could be read with more profit by the student new to clinical work, and this second edition will assuredly be welcomed by him.

*Surgery of the Stomach and Small Intestine.* By J. SHELTON HORSELEY, M.D., Attending Surgeon, St. Elizabeth's Hospital, Richmond, Va. London and New York: D. Appleton and Co. 1926. Pp. 325. 21*s.*

THIS monograph has one highly commendable feature; there is included a section of 36 pages on the physiology of the stomach and intestines. This gives us a clue to the author's work. His outlook is always physiological and his treatment is moulded by such considerations. Ethylene is adopted as the routine anæsthetic because it seems to affect cardiac activity less than any other known anæsthetic. Yet ether must be added at times to obtain relaxation. Nitrous oxide and oxygen for long operations is condemned. The advantages of some form of local anæsthesia are conceded, but its limitations are recognised. Under the surgery of gastric ulcer considerable prominence is given to the author's method of pyloroplasty, but the place of other operations is duly acknowledged and in this respect a well-balanced judgment is given. A meagre account only of gastro-jejunal ulcer appears, and very little guidance for the treatment of this distressing complication. Where the Billroth I. operation is performed the duodenum is sutured to the lesser curve extremity of the stomach lumen, a procedure which must restrict the applicability of the method. The surgery of the small intestine is represented almost solely by obstruction. It has been given less detailed consideration than diseases of the stomach. The chapter on diagnosis of gastric disorders by a collaborator of the author is only moderately good. It would be easy to point to other defects in the book, but the good points outweigh occasional failure to reach the high standard set by the better sections.

### HEALTH OF THE WORKERS.

By Sir THOMAS OLIVER. London: Faber and Gwyer, Ltd. 1925. Pp. 226. 2*s.* 6*d.*

THIS small volume is intended to meet the needs of all members of the community, not merely those of our professional colleagues. In size it is little more than a pocket-book; but the author has condensed into its ten chapters a vast amount of interesting and useful information. Throughout the modern view of industry is presented—viz., that occupation should be health-giving, and that no man's occupation should be a menace to his health or a risk to his life. How far industry falls short of this ideal is set forth, and how the ideal may be attained is pointed out. Sir Thomas Oliver has himself taken no small part in ameliorating the lot of the worker and in minimising many of the risks to which in the past he was exposed, particularly in regard to miners' phthisis and lead poisoning. Short but clear accounts are given of many different occupational diseases; the facts stated may generally be accepted as accurate.

We commend this book especially to panel practitioners working in industrial districts.

### THE ASSAYING OF BRABANTIUS AND OTHER VERSE.

By C. S. SHERRINGTON. London: Oxford University Press. 1925. Pp. 67. 4*s.* 6*d.*

PROF. Sherrington publishes a slender collection of verse much of which has already appeared in the *Oxford Magazine.* He uses in the small selection a good many metres with facility, showing command of vocabulary and simile; nor are the poems a direct reflection of the work of others, as must so often happen with the poet whose main work lies outside the strict business of literary construction and expression. On the contrary, in an austere and picturesque way he is quite original as well as often melodious. The little volume closes with a quintette of sonnets in which he shows himself able to write of large things within the limits so straitly laid down by the form, and one of these, entitled "Speech," is notable in this way. Prof. Sherrington takes his place rightly among a growing group of medical men who have turned to verse for the expression of their intimate thoughts.

### THE MOSQUITOES OF EGYPT.

By T. W. KIRKPATRICK, B.A., F.E.S., Senior Entomologist, Ministry of Agriculture, Egypt; Anti-Malaria Commission of the Egyptian Government. Cairo: Government Press. 1925. Pp. 224. Piastres 30.

THIS imposing memoir is a much more serious contribution to medical entomology than its title would leave one to believe. In scope it reaches far beyond the confines of the country with which it deals; not only are the anatomy, morphology, and habits of the imago, larva, and pupa accurately described, but the classification and the somewhat ponderous synonymy, which have burdened this branch of entomology, are, it is hoped, finally unravelled. In fact, we know of no other publication of its size which deals with the subject so exhaustively. The clearness of the type, the exact and beautifully executed line drawings (the work of Mr. Eugène Kassessinoff), which are grouped together for the most part in 24 plates forming an appendix to the volume, are specially to be commended. The arrangement of the subject-matter is logical and there is a complete index. We congratulate the author, the Ministry of Agriculture, and the Government Press of Cairo on producing such an excellent piece of work.

### MAISTRE WACE.

A Pioneer in Two Literatures. By J. H. PHILPOT. M.D. London: Methuen and Co., Ltd. 1925. Pp. 155. 7*s.* 6*d.*

DR. Philpot, already known as a novelist under the name of Philip Lafargue, has here given us a charming little study of some of the work of a writer who is almost unknown except to specialists. Maistre Wace was an Anglo-Norman poet, born in Jersey in the first decade of the twelfth century, who wrote the Roman de Brut, a history of the British kings from the time of King Arthur, and as a continuation, the Roman de Rou—namely, the history of the Dukes of Normandy and the Norman Conquest. Wace is probably forgotten by most people as the author of the Roman de Brut, but not very long after his death the poem was expanded by Layamon into his Brut, one of the landmarks of English poetry. The Roman de Rou, however, about the time of Richard II., began to be forgotten, owing to Norman French becoming a dead language, and it was not until the seventeenth century that the antiquary Duchesne copied out the first part of the poem. It was not printed until 1827, when Mr. Pluquet issued an edition at Rouen, and 50 years later a German scholar, Dr. Andresen, issued an edition with a valuable introduction and notes, which edition is the one Dr. Philpot has used for the purposes of an essay which all those interested in the history of their country should read. With much of the matter of the poem many of the more senior among our readers will probably be familiar, from Miss Yonge's delightful study, the Little Duke, otherwise Richard the Fearless, son of William Longsword and grandson of Wace's "Rou," who was Rolf, Duke of Normandy. One passage of the Roman de Rou is famous as being the most complete account of mediæval nautical matters which we have, though some of the technical terms are difficult to understand. Dr. Philpot gives a translation of the passage on p. 56 et seq., though he confesses that he is not satisfied with it. Those who would like to make a further attempt will find the original in the appendix, p. 143. In view of the possible appearance of a second edition we may note that the page references in the Table of Contents do not correspond with the page numbers in the body of the book until we come to the appendix.

Dr. Philpot's essay is one which should send its readers to the original for further information.

## JOURNALS.

Transactions of the American Association of Genito-Urinary Surgeons. Vol. XVIII. (Williams and Wilkins Company, Baltimore, Maryland).—This volume contains the papers and reports of discussions at the meeting of the Association held last May. A great variety of subjects has been dealt with. Dr. C. H. Chetwood has given a very complete review of stenosis of the bladder neck, a condition to which various labels have been attached—*prostatisme sans prostate*, atrophy of the prostate, and chronic contracture of the bladder neck. In summing up our knowledge of the condition, he states that contracture of the vesical neck is a term that embraces a variety of conditions having in common one principal feature—namely, obstruction to the urinary flow of the bladder outlet. In his opinion this obstruction may be congenital or acquired, and in the acquired condition inflammation plays an important rôle.—Dr. J. R. Caulk treats the same subject and deals more particularly with the use of the cautery punch as a remedy for prostatic obstruction. Dr. Caulk has found greater and greater scope for the use of his instrument, whereas in 1920 he considered that only 14 per cent. of cases of prostatic obstruction were amenable to treatment by the punch; during the last year he has employed this method of treatment in 63 per cent. of his patients.—Dr. H. G. Bugbee considers that in many cases that can be treated by means of a punch operation suprapubic drainage is a useful preliminary.—Dr. H. L. Kretschmer and Dr. Nathaniel B. Rathbun deal with strictures of the ureter, and Dr. J. L. Crenshaw and Dr. D. W. Mackenzie with bladder growths.—A full account of the treatment of urological infections by means of intravenous injections of mercurochrome and other urinary antiseptics is given by Dr. H. H. Young and Dr. J. A. Colston. They consider that, although none of these drugs act as a specific, valuable results have been obtained, especially with mercurochrome. Even although unexpected failures have occurred they consider that the sum total of results obtained are brilliant, and that a urological therapy of great importance has been opened up by the use of intravenous injections of urinary antiseptics.—Dr. W. F. Braasch and Dr. H. C. Bumpus, while less enthusiastic in their statements, endorse the value of intravenous chemotherapy in the treatment of urinary infections. But Dr. A. C. St. George, in describing the post-mortem examination of five cases of sepsis treated with mercurochrome, utters a note of warning. Whatever its value as an antiseptic, he points out it must be remembered that mercurochrome is a toxic drug and that the margin of safety between a therapeutic and a toxic dose is variable and small.—Other articles of interest are furnished by Dr. H. Cabot and Dr. F. S. Patch on the operative treatment of malignant kidneys and typhoid infection of the kidneys respectively.

# Reports and Analytical Records.

## (1) DIAL, LIQUID AND AMPOULES; (2) CIBALBUMIN; (3) DIOCAINE.

(Clayton Aniline Co., Ltd., Pharmaceutical Department, London, E.C. 4.)

(1) *Dial, Liquid and Ampoules.*—We have on previous occasions pointed out the hypnotic-sedative properties of Dial (diallylbarbituric acid) and its derivatives, and the properties of these drugs are so well known to the medical profession that it is unnecessary to go over the old ground. Up to now Dial has been available in tablet form only, but Dial liquid compound, each c.cm. containing 1½ gr. of Dial, for oral use, and ampoules, each containing 3 gr. of Dial, for hypodermic use, are now available. Dial has been used with special value among mental patients as a hypnotic, restoring the sleep habit effectively while the dose can be gradually reduced.

(2) *Cibalbumin* represents an aqueous and limpid solution of egg albumin which is aseptic and free from ferments and undesirable salts. The hypodermic, intramuscular, or intravenous injections of even large therapeutic doses have always been well tolerated, and symptoms of anaphylaxis or collapse have never been observed after the administration of doses appropriate to the case under treatment. Consequently this preparation would appear to be indicated in non-specific protein therapy. The mode of action of proteins is not clear, but their employment is receiving closer attention as the value of colloidal therapy becomes known to a wider circle of medical men. Cibalbumin has been introduced to provide a uniform permanent preparation of exact dosage with which to obtain reactions which manifest themselves only in definite proportion to the dose, and the manufacturers have obtained evidence that the resulting excitation is not excessive or dangerous. The range of conditions in which it has been recommended is very large, but it is clear that protein therapy should not be employed in patients whose general condition is bad, and a note from the pharmaceutical department of the manufacturers properly suggests that in neurotic subjects or in those who have developed certain therapeutic idiosyncrasies it should not be employed.

(3) *Diocaine* (para - diallyl - oxyethyl - diphenyl - diamidine) consists of a colourless powder melting at between 152° and 153° C., and soluble in water and alcohol. It has been found useful as a local anæsthetic in ophthalmology. There is medical authority for the claim that instillations are painless and non-irritant, while the anæsthesia produced sets in rapidly and is lasting. Diocaine substance is available in vials containing 0·5 g.

## ANGIOLYMPHE.

(Charles Zimmermann and Co. (Chemicals), Ltd., 9 & 10, St. Mary-at-Hill, London, E.C. 3.)

This preparation is stated to constitute a new treatment for tuberculosis "essentially different in its origin and effect to tuberculin or gland therapy." It is a vegetable remedy and the results of clinical trials must be awaited before any expression can be made on its merits, but a report has appeared in the *British Journal of Tuberculosis* from Dr. Jane Walker giving the results following over 1000 injections administered to 20 patients. The value of persistence is considered an essential point in the treatment irrespective of whether the patient appears to improve at first or not, considerable stress being thus put both upon the attention of the practitioner and the patience of the subject. The preparation has been employed in the treatment of lupus both in Paris and Charlottenburg. There appears to be nothing dangerous in the administration of the drug, but it need hardly be said that it should only be used under the strictest medical supervision.

# THE LANCET.

*LONDON: SATURDAY, FEBRUARY 27, 1926.*

## DR. AXHAM'S APPEAL.

It is hardly surprising that the Executive Committee of the General Medical Council, when it met last Monday, should have decided not to call a special meeting of the Council for the purpose of considering the restoration of Dr. Axham's name to the professional roll, inasmuch as no such special meeting has been held since 1903, when an important discussion on medical education was adjourned from May until July in order to ensure opportunity of full and frank consideration. The Executive Committee of the Council is a body of 12, without counting the President of the Council, who acts as Chairman. It consists at this moment, in addition to the President, of the representatives of the Royal Colleges of Physicians of London and Ireland, and of the Royal Colleges of Surgeons of England, Edinburgh, and Ireland, the representative of the University of Birmingham, a Privy Council representative from respectively England, Scotland, and Ireland, two of the English and the Scottish direct representatives. Such a body —*and every member attended the meeting*—cannot fail to have seen all the professional aspects of the case, while they are aware, far more fully than are the newspapers commenting upon their decision, of all the circumstances of the case, both precedent and immediate. They have been able to appreciate exactly how far the interests of Dr. Axham have been advanced to further those of others, while they are bound to look at his case strictly in connexion with the duties of the Council as a whole in respect of the Medical Acts, remembering that appeals for restitution to the Register are likely to come before the Council at every session and that special sittings would break alike the financial resources of the Council and the available leisure of its members. It may be argued that Dr. Axham's is an exceptional case, but the fact that he waited 15 years before making his appeal for restitution surely relieves the Council from the responsibility of taking immediate and unusual action.

◆

## PRIVATE PRACTICE AND PREVENTIVE MEDICINE.

The Annual Oration of the Hunterian Society was delivered on Monday last by Sir George Newman, who took for his subject the part played in the development of preventive medicine by the private practitioner, and was able to show that, for over 200 years, what may be called hygienic prophylaxis has largely depended for its progress upon the wisdom and enterprise of individual doctors, drawing for their justification of procedures upon personal experience of disease and therapy. From this point of view the dates in the lives of the two Hunters, and notably in the case of John, will be seen to coincide in a striking manner with medical developments taking place at far off centres and resulting from widely different schools and schemes of work. This was well illustrated by Sir George Newman in a list of collateral medical events, from which we note that John Hunter was born just as Isaac Newton died, and was a link with the wonderful scientific developments of 1685; that William Hunter came to London in the year of the highest mortality of the eighteenth century, when the public and the doctors were alike shaken in their optimism; that John Hunter followed him just as Haller's "Physiology" was published, blending the scattered and often pedantic teachings of the past with the broad and living views of to-day; and that John Hunter was elected to the Royal Society in the same year that Sir George Baker identified lead in the cider presses as the cause of "the endemical colic of Devonshire," and laid down the pattern upon which inquiries into food contamination are still conducted. John Hunter, again, was in the full course of his lectures on surgery in the very period that the discoveries of oxygen and nitrogen made the problems of respiration comprehensible; he died just before the publication of Jenner's work on vaccination. Other interesting coincidences could be drawn from the parallel lists of dated events with which Sir George Newman supplied his audience, all going to show that the feature of medical practice in the eighteenth century was the range of widely separated work that was being brought together for collation and sifting—verily the exact hour for the arrival of John Hunter.

Upon scientific discoveries emanating from such widely different sources the practitioners of the eighteenth century laid the foundations which their successors have used in the development of the accepted routine and teaching of medicine generally; but the Hunterian Orator was able to show that, while doing so, they were in a special sense the pioneers of preventive medicine. The appalling mortality among certain classes of the population urged them to explore the circumstances of epidemic disease with the result that much of the influence of external environment in its causation became clear to them as well as the value of notification and the necessity of attacking systematically the problems of infantile mortality. The drunkenness of the second half of the eighteenth century is notorious; artists like Hogarth, authors like Smollett, a doctor, and many great divines drew attention to the shameful profligacy and degradation resulting from excessive drinking; and the doctors reacted to the message and insisted, for their patients, upon a restriction of spirit-drinking, advocating at the same time improved dietaries and a wider use of vegetables, fruit, tea, and coffee. Foul domestic conditions became recognised in particular association with disease, because the doctors of the eighteenth century pointed them out, and they were the first to think of the wage-earner in connexion with industrial welfare schemes. It was the individual knowledge of these men in regard to the way that many of their patients had to live that led the public to realise the necessity for the establishment of hospitals and dispensaries, alike to provide institutional care and protection for the sick and to be centres of medical education. We can well echo Sir George Newman's summary of these and other achievements of the eighteenth century doctors: "Epoch-making as that period was in anatomy, physiology, and the new principles of surgery as expounded and interpreted by the scientific giants of the century . . . it was still more far-reaching in the sphere of preventive medicine, which not only extended the frontiers of life for many persons then alive but laid the foundations of the public health system of the succeeding century." These things were brought about by private practitioners, the general conception of prevention arising out of a massing together of the clinical study, experience, and wisdom of individuals.

Sir George Newman closed his address by pointing out, appositely all will allow, that the creation of special medical services, in the realm of preventive medicine and elsewhere, while it has produced a new general order of things, leaves the individual practitioner still serving in the first line of defence against disease, and therefore as a pioneer in preventive medicine. The allegation that the public medical services are designed to exclude the private practitioner is no longer made by thinking people: but it is well that we should be reminded that the Poor-law Medical Service has 4000 medical officers for outdoor medical relief, nearly all of whom are private practitioners; that the Post Office has a list of 3500 private practitioners on its staff; that a large proportion of medical officers of health and medical men engaged by local education authorities are still private practitioners, and only 350 are whole-time officers; and that the same is the case with all the certifying factory surgeons. The working of the National Insurance service, therefore, forms only a portion of the official duties of private practitioners; but it is here Sir George Newman thinks that the practitioners of the twentieth century may use the legacies of the past to the greatest advantage, with their wider opportunity for the observance of early disease, and, accordingly, their increasing chances of ascertaining causes and of planning the appropriate methods of prevention.

◆

## MORPHINE AND HEROIN ADDICTION.

We print elsewhere a section from the report of the Departmental Committee on Morphine and Heroin Addiction dealing with precautions to be observed by practitioners in administering those drugs. Hardly less important are the Committee's conclusions in respect of various proposals made by the Home Office for the tightening up of legislative restrictions. The existing Dangerous Drugs legislation (more particularly Article 11 of the Regulations made under Section 7 of the 1920 Act) declares that the duly qualified medical practitioner is authorised to possess or supply the drugs only "so far as is necessary for the practice of his profession." The registered dentist, registered veterinary surgeon, or research worker is subject to a like limitation. In each of these cases the Home Secretary can revoke the authorisation if the person so authorised is convicted of an offence against the Act. The Committee deprecates this insistence upon a prior conviction in the police-court. It proposes an alternative likely to be more acceptable both to the medical profession and to the Home Office. The proposal is that the law should be altered and that a suitably constituted medical tribunal should advise the Home Secretary as to withdrawal of authorisation. It is suggested that there should be one tribunal for England and Wales and another for Scotland. Each should consist of a medical member appointed by the General Medical Council, another appointed by the British Medical Association, and a third appointed in England by the Royal College of Physicians of London, and in Scotland by the similar body of Edinburgh. The present legal assessor to the General Medical Council might be appointed assessor to the proposed tribunals. The issues in these cases are essentially medical—i.e., whether there was or was not justification for administering a particular drug. It would clearly be helpful to have a uniform standard of decisions rather than that the standard should vary with every bench of magistrates up and down the country. Undoubtedly, too, the tribunals would collect valuable information. The cases which would call for decision would be those of a doctor administering or supplying drugs to other persons or to himself. In the latter class of case the tribunal would be all the more preferable to the police-court. Elsewhere in the report it appears that the Home Office asked the Committee to say whether the law should require the names of doctor addicts to be supplied to wholesale chemists so that the latter might inform the Home Office of purchases made by such doctors. This rather far-reaching proposal was wisely negatived.

On the question of improper prescribing there has always been a doubt of the Home Secretary's power of control. The Committee proposes that, to remove the doubt, it be definitely enacted that dangerous drugs shall not be prescribed except bona fide for medical purposes, and that cases of improper prescribing by doctors be referred to the medical tribunals in the same manner as those of improper possession and supply. Another suggestion was that medical practitioners administering heroin or morphine should be obliged to notify the central authority. The obligation would assist the Home Office to detect instances in which a patient obtains the drug from two or more doctors concurrently; it would also indirectly diminish supply in doubtful cases, would strengthen the doctor's control over his patient, and would relieve the profession from irksome inquiries which at present are unavoidable. But compulsory notification is open to the grave objection of imperilling the confidential relations of doctor and patient. The Committee is content to advise that, instead of compulsion, a doctor should, in his own as well as his patient's interests, inquire from the patient as to the sources of supply of the drug and as to the names and addresses of any other practitioners consulted. Yet another proposal was that in certain circumstances a second medical opinion should be compulsory. Here again the Committee prefers the voluntary principle. It considers that the profession might voluntarily adopt the rule that it is highly advisable to have a second opinion in serious drug cases just as at present in certain operations (for example, the emptying of the pregnant uterus) a rule has in effect been established. If a patient cannot afford a second opinion the Ministry of Health would be prepared to lend the services of its regional medical officers. In considering possible changes of the law, the position of the non-dispensing doctor was not overlooked. Doctors who dispense have to keep a record not only of dangerous drugs purchased, but also of those supplied otherwise than by personal administration. The non-dispensing doctor has hitherto escaped, but the Committee thinks he might reasonably be asked to keep some simple record of his purchases, if only by pasting his invoices into a book. From time to time coroners and others have recommended enlarging the scope of the Dangerous Drugs Acts. The Committee does not think there is much danger of addiction arising from any preparation at present outside the Acts except, perhaps, chlorodyne. Some witnesses favoured the compulsory establishment of a definite standard of morphine content in the case of chlorodyne and advocated such a standard as would automatically bring the preparation within the Acts. The Committee came to the conclusion that there might be some advantage in securing that no preparation should be sold as chlorodyne which contained more than 0·1 per cent. of morphine. It found no evidence of any need to bring all morphine preparations within the Dangerous Drugs Acts or to lower the standard of strength at present fixed. It will be remembered that, a year ago, the Geneva Conference had something to say as to the scope of legislation, and that last August the Dangerous Drugs Act of 1925 gave effect in Great Britain to the international agreement to abolish the former limit of one-tenth per cent. in respect of heroin, which had previously been embodied in Section 8 (1) of the Act of 1920. All preparations of heroin are therefore now within the Acts without distinction of percentage.

On other and more general questions the Committee's report is reassuring. The Dangerous Drugs Acts and Regulations are having a restrictive effect of demonstrable significance. Addiction to morphine or heroin is reported to be rare in England and to be growing rarer. Addiction, it seems, is more readily produced by the use of heroin than by that of morphine, and heroin addiction is the harder to cure. The most important predisposing cause of addiction is inherent mental or nervous instability. Other predisposing causes are chronic pain or distress, insomnia, overwork, and anxiety. Often, it appears, addiction has resulted from previous use of the drug in medical treatment; special care is needed in the case of young patients. One witness of wide experience told the Committee that some practitioners were too cautious and administered the drug too late, with the result that, when at last it was given, the patient was so worn out and the relief so intense that the danger of addiction was all the greater. In so far as addiction is due to self-treatment to relieve pain or to the influence and example of other addicts or to indulgence out of curiosity or bravado, it is likely to diminish in the future under the restriction of modern legislation. The Committee examined evidence of the relative values of different methods of treatment, the abrupt withdrawal method, the rapid withdrawal, and the gradual withdrawal. The last of these was considered more generally suitable and more free from risk, entailing less strain upon the patient, and unattended by collapse. Clearly, however, there is no room for excessive optimism. With two exceptions the most sanguine witnesses did not claim a higher proportion of lasting cures than from 15 to 20 per cent. Permanent cure is the exception, relapse is the rule. More successful results could be obtained if this country possessed more institutions where special treatment was available, and if addicts could be compelled by law to undergo such treatment.

◆

AMONG the 15 candidates recommended by the President and Council for election to the Fellowship of the Royal Society are several workers in medical or allied science. The recent work of Dr. J. A. Arkwright at the Lister Institute of Preventive Medicine on the filterable virus of foot-and-mouth disease was the subject of a leading article in THE LANCET of Feb. 6th. Dr. E. J. Butler has been director of the Imperial Bureau of Mycology at Kew since 1920. Lieut.-Colonel S. R. Christophers, of the Central Research Institute at Kasauli, India, has made valuable practical investigations into the scourge of malaria. Dr. H. Hartridge is a lecturer in the special senses and senior demonstrator in physiology in the University of Cambridge. University College, Reading, is honoured in the person of Dr. F. J. Cole, professor of zoology; and Liverpool will rejoice at the distinction to be conferred on Prof. W. C. M. Lewis for his researches in physical chemistry.

# Annotations.

*"Ne quid nimis."*

## SHORT WEIGHT AND MEASURE.

SOME years ago the Board of Trade directed the adoption of the thermal unit for the supply of gas for domestic purposes, and since that time no consumer has paid unwittingly for nitrogen or other inert matter which may be contained in the gas supplied to him by the approved company. Thermic value is not the only property of the domestic gas supply which matters to the consumer, though it is the most obvious: in regard to the important matter of food supply caloric value is the most prominent factor, and in the new dietary which has recently been worked out by the Army Medical Department for the British soldier the caloric values of protein, fat, and carbohydrate have been carefully regulated and the total number of calories brought up to an agreed figure. The Food Council, which has just presented its report to the President of the Board of Trade,[1] does not go so far as this, but it does propose that certain specified foodstuffs, including a large proportion of the staple foods, should in future be retailed exclusively by net weight. As the law stands at present it is quite legal, except in the case of bread and tea, to sell any foodstuffs by gross weight—that is to say, that the weight of the wrapper or container is included as part of the weight of the commodity demanded. The vendor's weighing-machine is already inspected under existing legislation and its accuracy controlled, but there is a curious misapprehension current that the placing of a counter-weight in the weight pan is illegal, and the Food Council thinks it should be widely known that the practice is not only legal, but has much to recommend it. The short weight arising from this and other causes may be and probably is individually quite small, but a series of individually small deficiencies in weight or measure on the housewife's weekly budget becomes considerable, and the Food Council had instances before it in which short weight and measure resulted in the housewife paying 8½d. per quart for milk instead of 7d., 1s. 11d. for meat instead of 1s. 8d., and 2s. 9d. for butter instead of 2s. 6d. Apart from the Edinburgh Corporation Act, it has been found almost impossible to obtain a conviction even for the persistent giving of short weight and measure; unless the inspector actually sees the weighing or measuring operation and can prove that the fraud in the weighing or measuring was wilfully committed, conviction has not followed. The Food Council therefore now recommends that legislative effect should be given in the present session of Parliament to its recommendation that meat, butter, cheese, cereals, sugar, coffee, jam, and potatoes (to name the headings only of a long list) should be retailed exclusively by net weight unless sold in quantities less than two ounces or in single pennyworths or less. It goes further than this and recommends that most of these foodstuffs should be retailed only in quantities of two ounces, four ounces, eight ounces, one pound or multiples of one pound. It is a sinister fact that many food products now on the market are put up in 15-oz. packets. The quantity may be plainly stamped on the package to protect the vendor, but undoubtedly people get into the habit of regarding these packets as pound packets, and in some cases the contents have actually been a pound at first and have later been reduced to 15 oz. The Council had before it much similar evidence of jam pots which could only contain 11 oz., of milk bottles, many of them something under one pint in content, and so on. Large retailers admitted that they were unable to face the wholesaler who did not give them the quantity he purported to sell. That being so, how futile [illegible] the report, is it to expect that the housewife defend herself against traders who give short weight and measure. The report leads up to the main recommendation, that the giving of short weight and measure should be a statutory offence applying to wholesale trade as well as to retail trade, and that the powers of administration of the new Act should be vested in local authorities at present administering the Weights and Measures Acts. There seems no reason why the recommendations should not work smoothly. The principles are the same as in the case of bread and tea where the object has been obtained without friction and without giving rise to increase in the cost of living or the production of unemployment, which have rather absurdly been claimed as likely to result from the honest proposals. The modest protection to the purchaser given by the suggested Act should become law in the present session of Parliament.

## ACUTE POISONING TREATED BY LUMBAR PUNCTURE.

A CARDINAL principle in the treatment of accidental poisoning is to hasten the elimination of the poison by every available channel. In poisoning by alkaloids venesection followed by intravenous infusion of normal saline solution has often been found useful. Lumbar puncture has recently been tried with the same end in view. At a meeting of the Vienna Medical Society Dr. F. Redlich discussed the methods used in the third medical clinic for the treatment of severe poisoning, chiefly in cases of attempted suicide. Within the last two years this clinic has had over 160 cases of the kind with 21 deaths. These included 25 attempts with veronal with 11 deaths, and Dr. Redlich has treated 13 cases of poisoning due to this drug by lumbar puncture. The cases chosen were those which were severe, but not actually moribund. The quantity of poison ingested was known only in two cases, and in these at least 5 g. (i.e., some 80 gr.) of veronal had been taken. Both recovered, as also did two other patients. In 12 cases the cerebro-spinal fluid was tested for veronal, and out of nine cases reported positive seven died; out of three cases reported negative one died. Luminal, corrosive sublimate, and lysol were also detected in the cerebro-spinal fluid in various cases, so that Dr. Redlich feels justified in recommending repeated and extensive removal of cerebro-spinal fluid in poisoning. It is, he considers, a safe method of removing part of the poison from the body, and especially from that system most susceptible to its action—the central nervous system. Other treatment is not, of course, neglected, including cardiac stimulants, stomach washes, and injections of strychnine and lobeline.

## A PHYSICAL STUDY OF MEDICAL PERCUSSION.

Dr. A. Gilbert, Dr. A. Tzanck, and Dr. R. A. Gutmann, writing in the *Paris Médical* of Jan. 9th, point out that the classical accounts refer to the medical percussion note as having three qualities—namely, intensity, frequency, and timbre—and they instance the diversity of opinion amongst clinicians as to the relative importance of these qualities. Their own view is that there is a fundamental difference between musical notes and noises, that there is usually complete similarity between the conditions required for producing *noise* and those obtaining in medical percussion, and that while analysis of sounds in general shows the three qualities mentioned to be intrinsic properties of musical notes, resonance (*sonorité*) may be set up in the "acoustic field" by both musical sounds and noises. Details are given of an arrangement whereby a perforated band is made to pass over the aperture of a tube through which air is blown in a steady stream. When the perforations are regularly spaced a note is produced which rises in pitch with increasing speed of the band. On the contrary, when the perforations are irregularly spaced, no alteration in pitch can be obtained, the sound produced being a pure noise. By means of another instrument, the phonoscope of Weiss, the authors obtained photographic records of different sounds. These tracings show clearly the rhythmical nature of all musical sounds whether consonant or dissonant, as opposed to the isolated nature of noise vibrations. Only in the case of a cavity freely communicating with the outside air can a percussion sound be properly considered musical, when the terms intensity, frequency, and timbre can be applied. On this view Wintrich's percussion sign is dependent on the difference between a musical note and a noise, not, as is usually taught, on alteration of the pitch of the note. Percussion reveals two things—the presence or absence of gas in the subjacent tissues and the physical relationship of gas to tissue. The presence of gas leads to resonance, its absence to dullness. In normal lung the gas must be considered as existing in small compartments not in free communication with the outside air. Evidence is put forward to prove that, when gases are thus pent up in the tissues, a state of hypertension obscures the resonance to percussion, while relaxation leads to a Skodaic note, even if the quantity of gas be small. A tabulated list of the different degrees of resonance and the clinical conditions with which they are associated concludes a paper which is a valuable addition to our knowledge of the physical basis of percussion sounds.

## A PROBLEM IN STATE MEDICINE.

THOSE persons who complain about any State interference with the relationship between doctor and patient and those who favour a whole-hearted scheme of State medicine will alike find much of interest in the present situation in America as set out in a recent issue of the *Journal of the American Medical Association*. As a result of the World War Veterans' Act of 1924 any ex-Service man who served in any campaign since 1897 is entitled to treatment and care in hospital at the Government's expense, no matter what the origin of his complaint, no matter what its nature, and no matter what his capacity to pay may be. All that the applicant has to do is to prove illness or injury and then enter a Government institution for treatment by Government physicians and surgeons. The fact that the illness or injury bears no relation to any military service, being neither caused nor aggravated by this, does not enter into the matter at all. These provisions came into force in June, 1924, and in the first financial year their estimated cost works out at a sum exceeding one million pounds. With the gradual spread of knowledge among ex-Service men this demand on the American taxpayer is likely to increase in future years, while certain politicians, not content with this, are preparing Bills to extend such beneficiary treatment, under similar conditions, to Confederate veterans and to civilian workers who served overseas during the recent war. Other measures propose that not only shall hospital care be provided for any disease and disability of these members of the community, but also free medical attention and nursing for the rest of their lives. No one who admits American citizenship is likely to complain at the acceptance by his Government of responsibility for illness and disability caused or in any way aggravated by military service, even when the term "aggravated" is generously interpreted; but the treatment of disabilities not of Service origin comes into another category. It may be that in the future some Government will boldly assert that the health of the people is its prime concern and proceed to provide free medical advice and treatment for all by means of suitable taxation. Indeed, by extending the present benefits in America to cover all civilians who have worked in the Government's service at any time, to those who have helped the Government's cause by voluntary service of any approved variety, and so forth, most of the adult population would at once be covered. The immediate effect, however, of the provisions already in force is to tend to withdraw patients from the small cities and towns to the larger cities where Government treatment is available, and the American Medical Association, recognising the dangers of the situation, adopted a strong resolution at its last meeting of delegates calling on the Government to amend its War Veterans' Act. If a frank scheme of State medicine is intended there may be much that could be said for and against it, but the present situation is regarded by the medical profession in America as thoroughly unsatisfactory.

## BASE OR SALT FOR INJECTION.

THE preparation of basic bodies for subcutaneous and intravenous injection has long been a matter of debate. As a rule, alkaloids are administered in the form of soluble salts, such as hydrochlorides or sulphates, when hydrolysis occurs in the organism, with the setting free of the pharmacologically active-free base. Mr. W H Martindale suggests, in another column, it would be reasonable to suppose that if alkaloids could be administered in some form which yielded the free base more readily, the activity of the preparations should be enhanced. After a series of experiments with quinine, he has been led to believe that a compound of quinine and mannitol would be more efficacious than the hydrochloride. In this preparation the quinine is virtually in the form of free base, thus absolving the body from the necessity of performing hydrolysis. Although no clinical trials have yet been made, the author's enthusiastic thesis appears well grounded. Moreover, the same considerations would apply to substances other than alkaloids. For example, hydrochloride may not be the ideal form for administering insulin. Solutions of insulin hydrochloride are strongly acid, and it would be interesting to compare the activity of this salt with that of the free substance. There are, however, a number of immediate advantages in the use of the hydrochloride which can only be sacrificed on good cause shown.

## RECENT ADVANCES IN OBSTETRICS.

DURING the last 20 years the maternal mortality rate in childbed has not appreciably declined. The child-bearing mother, as Sir George Newman has recently remarked,[1] is not sharing equally with the rest of the population in the improved public health. Although statistics sometimes mislead, no one will deny that the persistence of this high mortality rate reflects little credit on the science of obstetrics. Many reasons have been put forward for failure, but one outstanding fact emerges—namely, that a large number of the fatalities could have been prevented by efficient antenatal supervision. Albeit the essential value of antenatal care has been known for long enough, its adoption is by no means universal, and Mr. Comyns Berkeley was not overstating his case when he said that "the majority of pregnant women in our country have no antenatal supervision of any kind."[2] We therefore warmly welcome the excellent chapter on antenatal care in Mr. Aleck Bourne's "Recent Advances in Obstetrics and Gynæcology."[3] Antenatal care, he there states, is the most important single line of forward movement of thought in midwifery during the last ten years. From the London Report on Puerperal Sepsis it appears that labour was spontaneous and normal in 22 per cent. of the fatal cases, and it is by no means certain that a number of these deaths could not have been prevented. Of the remaining cases where some form of interference during labour took place there is little doubt that the majority could have been saved. Exact scientific proof may be lacking, but clinically autogenous infection does seem to occur. It is now accepted that the vagina of the apparently normal pregnant woman may harbour streptococci. Of these, the majority are non-hæmolytic and seemingly non-pathogenic, but we are still ignorant as to the possibility of a biological metastasis of these organisms brought about by some specific factor connected with pregnancy. Mr. Victor Bonney, in his recent address published in our columns,[4] focused attention on this autogenous type of infection, and made a strong plea for the abolition before or during pregnancy of all septic foci, whether in the teeth, tonsils, or intestinal tract, as a means of preventing puerperal infection. Despite the large number of remedies advocated for the cure of puerperal sepsis none of them so far has stood the test of time, and the rational therapy of this disease has yet to be evolved. Some of the newer methods of chemotherapy have been systematically tested at Prof. Halban's clinic in Vienna, the results—largely negative—being set out in a book reviewed on p. 443. Biochemists have invested the condition of the blood and urine in pregnancy and Mr. Bourne gives an excellent résumé of their inquiry, which has established a number of isolated chemical facts awaiting coördination for practical clinical work. The toxæmias of pregnancy rank only second to puerperal sepsis as the cause of death amongst pregnant women. Third on the list comes hæmorrhage, where in a proportion of cases early recognition and hospital treatment would save life. Antenatal care would, however, prevent the majority of cases of puerperal sepsis and toxæmia, and when it is remembered that in England and Wales alone 30,000 women lost their lives during the last decade from causes directly attributed to childbirth, there is still room for advance in obstetric practice.

## A NEW JOURNAL OF CHILDREN'S DISEASES.

WE extend a hearty welcome to the *Archives of Disease in Childhood*, the first number of which has appeared this month. The new journal is issued by the British Medical Association,[5] who have been fortunate in obtaining the services of Dr. Hugh Thursfield and Dr Reginald Miller as editors. The journals already dealing with pediatrics in this country, though admirable in quality, are fewer in number than in most continental countries and in America, and there is an undoubted need of an additional medium through which, as Sir Thomas Barlow indicates in his introduction to the new issue, the numerous workers in various branches of children's disease may submit their observations for criticism and verification. The February number provides good illustration of the way in which this need is being met by the new journal, and promises much for its success. The articles which it contains are for the greater part devoted to the results of clinical research undertaken in children's hospitals. A paper by Dr. F. J. Poynton and Dr. W. G. Wyllie on hepatic cirrhosis in children offers a comprehensive review of an obscure subject. Four cases treated recently at the Children's Hospital, Great Ormond-street, are described; these cases all showed unusual features, and exemplify the difficulty of correlating clinical types of cirrhosis with particular pathogenic factors. The two familial cases, for example, were both considered on the clinical evidence to be portal rather than biliary in origin. The authors divide the cirrhoses into seven types, which are discussed severally, the morbid histology of each being illustrated by excellent photographs and colour-plates. Special attention is devoted to the biliary forms of cirrhosis, which in children are more commonly met with than those of portal distribution. These are considered under the headings of (*a*) hypertrophic, (*b*) congenital, and (*c*) obstructive biliary cirrhosis. Forms (*a*) and (*c*) are rare in this country; (*a*) and (*b*) show a remarkable tendency to familial incidence. Congenital cirrhosis may occur with or without obliteration of the bile-ducts. The pathogenesis of this form has never been fully established.

[3] J. and A. Churchill. 12s. 6d.

[4] THE LANCET, Jan. 23rd, 1926

[5] London: Brit. Med. Assoc. House, Tavistock-square, W.C. 1. Yearly subs. (six numbers), 25s. Single number 4s. 6d.

Dr. John Thomson regarding a malformation of the ducts, and Sir H. Rolleston the hepatic cirrhosis, as the primary and essential lesion. The possibility is suggested that a mild congenital case may be the precursor of a hypertrophic cirrhosis. In another article Dr. G. A. Sutherland describes, by means of polygraph tracings taken at different stages, a case of severe heart-block treated by injections of adrenalin, and discusses the rationale of this treatment The three papers describing investigations on rickets contain numerous points of interest Taken collectively they impress on the reader the extreme difficulty of standardising the diagnosis of rickets, and consequently, the reservations which must be attached to conclusions drawn from statistics of incidence All the three authors—Dr H. Mackay, Dr. D. Paterson, and Dr. R. Darby—based their diagnoses on radiographic examination of the wrist. Dr. Mackay frankly admits that the incidence of slight rickets is much higher than the radiographic diagnosis will indicate, and looks to examination of the blood as the diagnostic method of the future. Dr. Paterson and Dr. Darby found that the rickety process in the wrist was healed in the great majority of cases. Such cases could not be diagnosed with certainty as active rickets, and appear to have been regarded as inactive, yet it may be doubted if the presence of a healed focus in bone should be taken as evidence that the activity of a disease which manifests itself in so many systems has been arrested. There are a number of other contributions which will repay the reader's attention. All interested in pediatrics may expect much from future issues of the *Archives.*

## TETANUS ANATOXIN.

OUR Paris correspondent has already referred[1] to the work on active immunisation against tetanus done by Dr. Zoeller, of the Val-de-Grâce, and Dr. Ramon, of the Pasteur Institute. On Feb. 2nd they made a communication to the Académie de Médecine on their tetanus anatoxin, and a clue to its importance is to be found in the words in which Dr. Roux, the head of the Pasteur Institute, summed up his impressions. "I cannot," he said, "sufficiently congratulate the authors on their work, both from the point of view of its practical value and of its general importance to physiology." From what was said it appears that tetanus anatoxin, derived from tetanus toxin, is quite as effective an antigen as the parent substance. Tetanus toxin is very poisonous, but anatoxin can be given in large doses without provoking any reaction demonstrable clinically. Yet it confers an active immunity of permanent, or at any rate long, duration. The principles governing the conversion of toxins into anatoxins are applicable to a large group of poisons, whether they be derived from the vegetable or the animal kingdom—e.g., from bacteria, plants, or snakes. In each case a substance is obtained which is at the same time innocuous and capable of conferring permanent active immunity on the recipient. In one series of experiments Dr. Zoeller and Dr. Ramon gave a subcutaneous injection of 0·5 or 1 c.cm. of anatoxin tetanus to human beings. A month later the serum of the vaccinated was only slightly more effective than control serum in protecting guinea-pigs from a fatal dose of fresh tetanus toxin. But a month after a second injection of anatoxin the serum of the vaccinated was from one to ten times more effective than that of control serum; and eight days after a third injection of anatoxin the serum of the vaccinated was from 500 to 3000 times more effective than the control serum. It was also found that anatoxin could be given with antityphoid (T.A.B.) vaccine, without the one interfering with, or neutralising, the other. Indeed, it would seem that the reaction provoked by the antityphoid vaccine promoted the action of the anatoxin. In another series of experiments it was found that tetanus serum could be given simultaneously with tetanus anatoxin; in other words, active and passive immunisation may be practised simultaneously. As some time is required to establish active immunisation, we cannot yet dispense with the present system of passive immunisation; but the authors of this communication foresee that in future campaigns soldiers will be vaccinated with tetanus anatoxin at the same time that they are vaccinated against typhoid and paratyphoid fever. The two first injections of anatoxin can be given with the typhoid vaccine, and as soon as a wound is inflicted the soldier can be given a third injection of anatoxin, the effect of which will be very potent in a few days. The debate at the Académie which followed this communication merely served to stress its importance, and the only discord was produced by conflicting claims for priority in the discovery. Although the facts quoted are extremely interesting and may be of great general importance in the production of active immunity, it is doubtful if their application to the particular infection is of practical moment. Tetanus is, happily, so rare a condition in civilian life that its prevention by toxin inoculation is outside the range of practicability. The modified toxin may, however, prove very useful in the manufacture of antitoxin and in some kinds of veterinary practice.

## THE OPTICAL CONVENTION.

THE first Optical Convention was held in 1905; the second, and last, was held in 1912. The time indeed seems ripe for another review of the achievements of British science and industry as applied to optics, and to take note of the remarkable advances that have been made during and since the war. How great these advances are it is the object of the convention to show. In the opinion of the organisers there has never been a time of more rapid progress, and the difference between the present position of optics in this country and the position before the war is not sufficiently recognised. Great Britain, it is claimed, has gone far towards regaining her old position of leadership. The first convention, it may be recalled, met under the presidency of Sir Richard (then Dr.) Glazebrook; the second under that of the late Prof. Silvanus P. Thompson: in 1926 the president will be Sir Frank Dyson, the Astronomer Royal. The long list of distinguished vice-presidents is suggestive of the number of sciences concerned in the advance of this key science of optics, and is also a guarantee that the convention will be of wide interest as well as of importance to specialists. The programme gives the same assurance. Apart from the exhibition and lectures there will be a large number of papers on scientific and technical subjects, included under the headings of optical theory, history and education, optical glass and the manufacture of optical elements; astronomy, microscopy, spectroscopy, and interferometry; photography, ophthalmology and spectacle manufacture; cinematography and projection; colour; photometry and illumination; surveying, including aerial surveying; and optical apparatus in the fighting services. There will also be special discourses which are to include popular lectures, and there will be a large exhibition arranged in sections called experimental and research, historical and commercial. The first section will contain exhibits by individuals, research laboratories, and institutions; the second will include the reproduction of historical experiments, whilst the third will be made up of exhibits by British manufacturing firms in all branches of the optical trade. Not even optical delusions will be neglected, and Captain Clive Maskelyne is amongst those who have promised their aid for purposes of entertainment. As before, a volume of Proceedings will be issued, and this, like the previous ones, should prove a valuable document, showing, as it will, the present state of the science in this country. The convention is to be held at the Imperial College of Science and Technology in South Kensington, London, and will last from April 12th to 17th. Applications for information or membership should be addressed to the secretary, at the offices of the convention, 1, Lowther-gardens, Exhibition-road, London, S.W. 7. The appearance of such a convention is almost as uncommon as that of a comet, and its rarity, as well as its intrinsic interest, ought to commend it to the educated public.

---

[1] THE LANCET, Jan. 23rd, 1926, p. 197.

## DERWENT WOOD.

MEDICAL men will have personal reason to regret the death of Mr. Francis Derwent Wood, R.A., the well-known sculptor, which occurred at a London nursing home on Friday last as a sequel to a severe operation. Derwent Wood was a true cosmopolitan, for, born of an American father and an English mother, he was educated in Switzerland and Germany, and married a famous Australian singer; but his work as a sculptor was done in this country, where he had taught in the Glasgow art schools and in the two famous metropolitan schools, the Royal College of Art, South Kensington, and the Slade School, as well as at the Royal Academy. He was a frequent exhibitor at the Academy both of portraiture and imaginative work, was elected A.R.A. in 1910, and R.A. ten years later. During the war he became associated with medicine as a constructor of face-masks for disfigured soldiers, and in the columns of THE LANCET he described very fully the use of these masks in the mutilations of facial wounds. Disclaiming any attempt either to alleviate suffering or to restore function, he described his work as beginning where that of the surgeon is completed. It was the mental distress of physical deformity which Derwent Wood's work was designed to relieve, his cases being generally those extreme ones that plastic surgery had been compelled to abandon. The psychological effect was what he aimed at with the fullest sympathy, and many a patient behind one of these masks acquired the old self-respect and self-reliance, discarding despondency under the feeling that his presence was no longer a source of melancholy to himself nor of sadness to others. "So far as my treatment goes," the sculptor wrote in our columns, "the size of the areas affected is negligible. In theory, it is as easy to make a mask for a whole face as for a space an inch square to cover a small palpitating area such as is often done in the case of skull wounds. The essential of the treatment is the restoration of features; the features may have been originally ugly or beautiful. As they were in life so I try to reproduce them, beautiful or ugly; the one desideratum is to make them natural." On all hands Derwent Wood was allowed to be one of the finest plastic workers modern art has known.

## TRANSMISSION OF DENGUE BY MOSQUITOES.

THAT dengue is carried by mosquitoes has long been the impression of those who have suffered from both. Lieut.-Colonel J. F. Siler and two other officers of the Medical Corps, U.S. Army, have subjected the question to experiment in the Philippines, and they now report that dengue is carried by *Aedes egypti* (commonly called *Stegomyia fasciata*), the mosquito that transmits yellow fever. A brief note of their work appears in the *Military Surgeon* for January, the complete account being reserved for the *Philippine Journal of Science*. The 64 volunteers who participated in the research were soldiers recently arrived from the United States and free from disease, including syphilis. They were put to live in a military hospital in Manila, in a ward specially made mosquito-proof and kept mosquito-free. Experiments were made with two mosquitoes, *A. egypti* and *Culex quinquefasciatus*. With the latter the results were negative, but out of 111 experiments with *A. egypti* 47 were successful. The mosquitoes used were grown in captivity from the egg upwards. Fertilised females were put to bite dengue patients, and the sated insects were then allowed to bite the volunteers. Thus it was learned that a case of dengue was infectious to the mosquito from 18 hours before onset to the end of the third day of the disease. The *A. egypti* itself does not become infective for 11–14 days, but then remains so for the remainder of life, certainly up to 75 days; infection is not transmitted to the offspring. A patient, bitten by 2–10 infected mosquitoes, develops dengue in from 4–10 days, usually within six. Passage of the virus six times from man to mosquito and again to man neither attenuated nor increased its virulence. The whole research was well planned and carefully carried out, and the complete report will be awaited with interest.

# The Services.

## ROYAL ARMY MEDICAL CORPS.

Lt.-Col. and Bt.-Col. Sir E. S. Worthington retires on retd. pay.

Maj. R. G. Meredith is placed on the half pay list on account of ill health.

The undermentioned Capts. to be Majs.: T. O. Thompson, J. G. Gill, S. M. Hattersley, and J. W. C. Stubbs (Prov. and remains secd.)

Temp. Lts. J. M Johnston, R. J. G. Hyde, and A. K. J. Finch to be Lts. on probation, and relinquish their temp. rank of Lt.

R. V. Franklin to be Lt. on probation and is secd.

### ARMY RESERVE OF OFFICERS.

Capt. N. Kerr, from T.A., Gen. List, Edinburgh University Contgt., O.T C., to be Capt.

### TERRITORIAL ARMY.

C. W. F. Greenhill (late Surg. Lt., R.N.) to be Capt.

2nd Lt. T. F. Greenhill (late H.L.I.) to be Lt.

Supernumerary for Service with the O.T.C.: H. E. A. Boldero (late R.A.M.C.) to be Capt. for service with medical unit, University of London O.T.C.

J. F. Smith (late Surg. Lt., R.N.) to be Capt. for service with medical unit, University of London O.T.C.

## ROYAL AIR FORCE.

E. J. Jenkins is granted a short service commission as a Flying Officer for three years on the Active List.

Tempy. Lt. H. R. Peel, General List, Dental Surgeon Army, is granted a temporary commission as Flying Officer on attachment to the R.A.F.

## MILITARY HOSPITALS RESERVE.

The reorganisation of the "Home Hospitals Reserve," under the designation of "The Military Hospitals Reserve," has been approved and the qualifications for enrolment have been issued in an Army Order. This Reserve will consist of warrant and non-commissioned officers and privates only, with an authorised establishment of 2000. The functions of the reserve will be (*a*) to staff the military hospitals and other establishments maintained by the regular medical services upon the mobilisation and withdrawal of the regular R.A.M.C. for duty in the field; and (*b*) to provide reinforcements for the medical units of the expeditionary force overseas after mobilisation. Membership will be entirely voluntary and the personnel will be provided by the St. John Ambulance Brigade for England and Wales and Northern Ireland and the St. Andrew's Ambulance Corps for Scotland.

The age limits for enrolment will be from 19 to 40 years of age, and no member will be permitted to remain in the Reserve after he has reached the age of 45 years. Every applicant must be in possession of the first-aid certificate recognised or granted by the St. John Ambulance Association or St. Andrew's Ambulance Association, and, in addition, obtain a nursing certificate recognised by those bodies within a period of 12 months after enrolment. A proportion of the total establishment of each rank in the Reserve will, in annual rotation, receive training for eight days under military arrangements. A member of the Reserve will receive, both during training and on coming up for duty in replacement of a member of the R.A.M.C., pay and allowances at the rates laid down for a man of the corresponding army rank and trade group (if qualified) whom he has been detailed to replace on mobilisation, and promotion to fill the authorised establishment of ranks during service in the Reserve will be given according to service, merit, and qualifications.

Surg.-Maj. R. Vella, half pay list, late R. Malta Artillery, on attaining the age limit for compulsory retirement, is placed on retd. pay.

## CLXII.

## THE TREATMENT OF CHRONIC TONSILLITIS.

### II. Tonsillectomy in Adults and Children.[1]

### *Preparation of the Patient.*

The child or adult should be admitted to hospital in the afternoon before operation. Unfortunately, owing to the lack of sufficient hospital accommodation, most children have still to be operated upon as out-patients. The heart, lungs, and urine should be examined. Castor oil or other purgative is given at night and weak tea or bovril on the morning of operation.

### *Enucleation by Guillotine.*

The Whillis-Sluder method of guillotine enucleation is as follows: (1) The patient lies in the dorsal position with the head hanging over the end of the table or with the shoulders supported by pillows and the head fully extended in good light. (2) When the patient is anæsthetised the gag is opened. (3) The operator depresses the tongue with Lack's spatula and exposes the lower pole of the left tonsil, the surgeon's left hand holding the guillotine. (4) The ring of the guillotine is hooked round the lower pole, the blade side next to the tonsil. (5) The tonsil is now pressed from below and behind upwards and forwards over the alveolar eminence of the mandible until the anterior faucial pillar and palate bulge forwards. (6) A finger of the disengaged right hand is placed on this bulging and the tonsil pushed firmly through the ring of the guillotine. In this process the tonsil is turned outside in, or "fliped" as we say in Scotland. As a rule it goes through the ring with a distinct jerk and the tip of the finger comes in contact with the ring of the guillotine. (7) The blade of the guillotine is now pushed home. (8) With a twisting movement the tonsil is removed from the mouth on the reverse surface of the instrument. (9) The anæsthetist now inserts a swab, held in curved forceps, into the tonsillar fossa. The surgeon changes the guillotine to his right hand and enucleates the right tonsil.

The child is now rapidly turned over into the prone position so that blood may run out of the mouth and, in order to assist in the control of hæmorrhage, cold water is poured with a marine sponge over the back of the child's neck. Within about 60 seconds the child, supported by a nurse, is able to sit up on the table with its legs dangling over one side. The child is then made to blow through each nostril alternately, in order to get rid of the blood which has accumulated in the nose. By this time it will usually be found on inspection that the hæmorrhage from the tonsil fossa has ceased and the child can be carried back to bed, where it is placed well over on one side with its head supported at the edge of two pillows and the face turned downwards over a shallow basin. As a rule the patient very soon goes to sleep.

Very little in the way of after-treatment is necessary. On the day of operation drinks of cold water are all that is really necessary, though some surgeons allow ice-cream, which is very popular with the patients. Thereafter porridge and milk, custard and soft foods are given, until gradually the child returns to normal diet. A purgative is given on the second night after the operation. The patient should stay in bed for two days. On the third day the child is allowed to get up and to go home on the fourth. E. Watson-Williams has pointed out that the risk of complication is far greater if patients are sent home shortly after operation. A mild antiseptic mouthwash and gargle, such as phenol sodique, should be used for a week; 10 gr. of aspirin stirred in a tumblerful of lukewarm water and used as a mouthwash or gargle often seems to relieve the pain.

### *Enucleation by Dissection.*

Enucleation by dissection can be done in adults with the aid of local anæsthesia. The method is as follows: (1) Hypodermic injection of heroin and atropine half an hour before operation. Spray throat with 10 per cent. cocaine, taking care that patient spits it all out. (2) The surgeon sits on a high stool with his back to the window, while the patient sits in a chair facing the window. On a dark day reflected light from a forehead mirror should be used. (3) Depress the tongue and, with tonsil syringe and curved needle, inject the anterior and posterior pillars with the local anæsthetic solution (adrenalin (1–1000) ♏ 4; novocaine (1 per cent.) ♏ 60; sterile saline solution ʒ iii). Then grasp tonsil with vulsellum, pull it inwards and inject with straight needle into tonsil bed, lateral to the anterior pillar—i.e., between tonsil and superior constrictor. Lastly, the posterior palatine nerves are injected at the foramen. (4) Wait 10 to 15 minutes. (5) Insert tongue depressor and, with sickle-shaped knife held in left hand, make incision low down just behind left anterior pillar and run the knife up to junction of pillars. (6) Remove spatula and insert self-retaining depressor; grasp tonsil with uterine vulsellum, and pull it inwards while an assistant with a retractor hooks the anterior pillar out of the way. (7) With scissors curved on the flat clip around the tonsil, keeping close to the bluish-white capsule. The upper pole of the tonsil soon comes into view. Then draw tonsil forwards and snip behind it so as to free the tonsil from the upper part of posterior pillar. (8) Insert tonsil enucleator or forefinger between tonsil and fascia of superior constrictor to separate tonsil from its bed. (9) Reinsert pillar retractor and free tonsil from lower part of anterior and posterior pillars. (10) Pass cold wire snare over vulsellum and upper part of tonsil down to lower pole. Keep up traction with vulsellum and gradually tighten snare till tonsil is detached and removed. (11) Clean out tonsil fossa with swab soaked in peroxide solution and held in curved sponge-holder. Then examine tonsil bed to see that it is clean and dry. The right tonsil is now dealt with on the same lines.

In most cases there is no bleeding after the operation has been completed, but, if there is, a peroxide swab should be inserted into each tonsil fossa, while the patient continues to sit upright. Many surgeons prefer general anæsthesia—e.g., intratracheal ether—for enucleation of the tonsil by the dissection method.

### *Complications.*

*Hæmorrhage.*—Statistics vary very greatly as regards the frequence of serious hæmorrhage after tonsil enucleation. This may be explained by differences in the type of operation performed. Some surgeons say that hæmorrhage is more common after tonsillectomy than after the old slicing operation; others take the opposite view. There is general agreement, however, that severe bleeding is more common after enucleation by dissection under general anæsthesia than after the guillotine operation. This is probably because the latter is usually carried out in children. The accuracy with which cases are followed up and the personal equation are also important. Mollison had only 0·147 per cent. of hæmorrhage in 2000 cases, whereas McKinney and also Beaman Douglas reported 6 per cent. and Holger Mygind 8 per cent. The average appears to be from 0·5 to 2 per cent. Loeb has collected 62 cases in which death occurred from hæmorrhage. Vomiting of blood—altered or red—is very often the first warning that hæmorrhage is taking place. Extreme pallor and marked restlessness are other signs. As a prophylactic measure, calcium chloride may be given for two days before operation, or 10 c.cm. of horse serum may be injected. When hæmorrhage occurs the patient should sit up, supported by pillows, and light should be reflected into the mouth. A tonsil fossa full of coagulum is almost certainly the site of the hæmorrhage. The clot must be turned out and the fossa inspected to see if a piece of tonsil has been left; if so it should be removed. A swab, wrung out of hydrogen peroxide, friar's balsam, or carbolised resin, is now packed into the tonsil fossa, held there with the sponge-holder and changed as required. Usually this is sufficient to stop the bleeding. If, in spite of these measures, the hæmorrhage goes on, the bleeding vessel should be grasped with artery or tissue forceps, which may be left on for a time, or a thread ligature may be applied —often a matter of considerable difficulty. As an alternative the Watson-Williams or other form of well-padded tonsil clamps may be used. Suturing the pillars over a roll of gauze has been employed. As a last resort the patient may be made to stand up till he feels faint. In very severe cases transfusion of gum saline or of blood may be called for.

---

[1] An article on the Choice of Methods in Chronic Tonsillitis by Mr. Fraser appeared last week.

*Sepsis.*—Serious septic complications following tonsillectomy are rare, though some œdema of the uvula is very common. The chief complications attributable to septic infection after tonsillectomy are pneumonia, lung abscess, and empyema. Abscess of the lung and empyema may be due to inspiration of infected material at the time of operation (here the abscess—usually in the right lung—develops within 36 hours), or to blood infection—*i.e.*, through the pharyngeal plexus to the right heart and so to the pulmonary artery. These cases are most common after dissection under a general anæsthetic in which the operation is prolonged and there is much forcible swabbing of the tonsil fossa. In these cases the abscess develops later—in from four days to two weeks. Surgical scarlet fever sometimes follows tonsillectomy and is probably due to streptococcal septicæmia.

### *Results of Tonsillectomy.*

Recurrent attacks of tonsillitis are, of course, eliminated if the tonsils are enucleated. E. D. D. Davis states that a family doctor had informed him that during 18 months after operation he had not been asked to visit any of 30 children who had had their tonsils removed, whereas before the operation his visits had been frequent. In Edinburgh it is not uncommon for a mother of her own accord to bring up to the Royal Infirmary a second and, later, a third child for operation, because she has recognised the symptoms of throat trouble and has seen the good results of operation on her first child. It is wrong to tell a parent that tonsillectomy and removal of adenoids will prevent the child from catching cold, but right to state that colds will probably be less frequent and of shorter duration.

*Local Results.*—Asymmetry or adhesion of the faucial pillars are common, but insufficiency of the palate, with cleft palate voice and return of fluids by the nose, is very rare. Dryness of the throat is sometimes complained of and is probably due to injury to the ducts of the mucous glands in the soft palate which open just above the tonsil. In singers, if the tonsil enucleation be carefully done and if the patient refrains from using the voice for two months, the results are most satisfactory. As regards chronic simple inflammatory enlargement of the tonsillar gland, Crowe reports that in 38 per cent. the enlargement disappeared after tonsillectomy and in a further 50 per cent. the glands were only the size of a pea.

*Remote Results.*—Although the tonsils are an important source of focal infection, tonsillectomy does not always bring about a cure of the disease for which the operation was undertaken. In chronic toxæmia, with lassitude, anæmia, and anorexia, the results in well-selected cases are excellent. The results of enucleation in cases of early arthritis and myositis are very satisfactory and often brilliant (30–80 per cent. cures). In cases of rheumatic fever, St. Lawrence states that 84 per cent. showed a good result; on the other hand, Hunt and Osman reported that the percentage of recurrence was much the same in operated and non-operated cases. In rheumatoid arthritis, not only are the ultimate results very disappointing, but patients may have to stay in hospital for three months before they recover from the effects of the operation.

## BASIC QUININE AND OTHER ALKALOIDAL INJECTIONS.

BY W. H. MARTINDALE, PH.D., PH.CH.

HITHERTO it has been customary when introducing alkaloids into the tissues or into the venous circulation to employ them in the form of their soluble salts, but I think the scientific view is tenable that their therapeutic action depends almost entirely on the alkaloidal base which is liberated from the salt by the alkalinity of the body fluids. In the case of several alkaloids it has been experimentally verified in my laboratory that on mixing a solution of an alkaloidal salt with blood a considerable amount of base can be extracted by a suitable solvent. It is difficult to say who first pointed out the reaction which occurs, but Overton [1] has suggested that, in the organism, the salts of the alkaloids are split up by the alkali of the blood and lymph, their action being due only to the free alkaloids. No general clinical use of the knowledge has been made, due, no doubt, to the difficulty of making suitable solutions of these bases. The statement of Overton led Gros [2] to compare the anæsthetic effect of some bases and their salts, and in nearly every instance the base was shown to be considerably more active. Furthermore, some time ago I found the injectio *cocainæ et sodii bicarbonatis*, which is known to be more effective than an ordinary cocaine hydrochloride solution of the same strength, to contain the cocaine actually in such a form that it can be readily extracted as base by an immiscible solvent. Viewed chemically, this would, perhaps, not have been expected. The finding of this basic cocaine fitted in with certain views on the subject of "activated" alkaloids, which need not be dealt with in detail here.

### *The Use of Alkaloidal Bases.*

In view of the above statements, I am inclined to think that the use of the alkaloidal bases would be preferable to that of the salts, if suitable solvents could be found. In the spring and summer of 1924 I was fortunate in finding a hospital clinician willing to try several alkaloidal base preparations—e.g., atropine, morphine, and codeine. (There is a description of the work in the "Extra Pharmacopœia," Vol. I.). Although it was only possible to give small amounts of these alkaloidal bases, they were found in some cases to have the effect of much larger doses of the salts. The great difficulty is, of course, that all these bases are only slightly soluble in aqueous or other diluents which can reasonably be employed for injection. It may be recalled that Warrington Yorke [3] did clinical work with quinine base in a sesame oil and alcohol medium, but this does not quite meet the case. My view is that one should try to find some type of solution of the basic alkaloid, capable of ready dispersion through the body fluids. A. J. Copeland [4] and H. E. F. Notton, in their search for an anæsthetic more satisfactory than cocaine, have failed, I think, to acknowledge adequately the researches of Gros. They have reintroduced his suggestion to employ a readily hydrolysed alkaloidal salt, and, founded on this idea, a preparation of novocain and boric acid has been brought to the notice of the profession as a new substitute for cocaine. It might be added that novocain (ethocaine) borate was examined in 1912 by Gros,[5] who found it to have the greatest anæsthetic effect of the five novocain salts tested. The borates, being the salts of a very weak acid, have the advantage of being readily hydrolysed, so that their aqueous solutions contain alkaloidal base, as in the injectio *cocainæ et sodii bicarbonatis*. They are, however, in general, too unstable to be extensively used.

Searching in many directions for a solvent which would allow of the preparation of a fairly concentrated solution of basic quinine for injection, one of my assistants (S. Back, B.Sc.) suggested the use of the alkaloidal borate in conjunction with glycerin or mannitol. The two last-mentioned chemicals, in moderately concentrated solutions, convert boric acid into a stronger acid (a fact utilised in the titration of borates), and it was found that this stronger acid then combines with some of the alkaloidal bases, forming salts which are quite stable in solution. On dilution of these solutions with water the salts are rapidly hydrolysed, giving a solution of the alkaloidal base and boric acid.

### *Mannitol-Quinine.*

From the experiments carried out with quinine, the following formula for such a solution appeared to be the most satisfactory :—

Mannitol-Quinine: *Suggested for intracutaneous or intravenous injection.*

| | | | |
|---|---|---|---|
| Quinine base .. | 12·0 g. | Mannitol .. .. | 7·5 g. |
| Boric acid .. .. | 8·4 g. | Distilled water to .. | 100 c.cm. |

1 c.cm. contains 0·12 g. (approx. 2 gr.) of quinine base and 0·084 g. (1¼ gr.) of boric acid.

This injection contains, therefore, doses of quinine within clinical limits in a reasonably small volume of diluent. I suggest the convenient short name "Mannitol-Quinine" for it. It is easily made by rubbing the powders together with about half the required amount of water, then adding, as the alkaloid dissolves, sufficient to produce the necessary volume. The quantity of boric acid used is approximately four molecules to one molecule of the base (borates of this kind are known to be very complex). If it be desired to sterilise mannitol-quinine, it will be found that on heating to 100° C. a deposit of the alkaloidal base is formed, but this re-dissolves on standing at the ordinary temperature for a few hours. Mannitol-quinine has been put to the test of different storage temperatures, and it would appear to be quite satisfactory on this point. It remains clear and unchanged up to a temperature of 60° C. (140° F.), and no crystallisation occurred at as low a temperature as −6° C. (21·2° F.). Mannitol-quinine is amphoteric to litmus paper, but is in reality practically neutral, the pH value being about 7. On adding water it becomes slightly alkaline, owing to the liberation of quinine base by hydrolysis. At first an opalescence, probably due to colloidal quinine base, is usually formed, but this disappears upon the addition of more water (long before there is theoretically sufficient present to dissolve the base).

This suggests the use of a dilute intravenous mannitol-quinine, made by the dilution of 1 c.cm. of the concentrated solution to 10 or 20 c.cm., just prior to injection. A small point which needs obvious mention is the possibility of the cumulative effect from the 1¼ gr. of boric acid, if repeated ; but this is, perhaps, negligible. It would, however, need watching (novocain borate contains 47·1 per cent. boric acid ; the 0·1 g. tablets of commerce containing nearly ¾ gr., to be dissolved in 5 c.cm. of diluent). The addition of mannitol to injections is occasionally referred to and recommended in the literature. For example, C. C. Holman [4] stated that he employed a 5 per cent. solution of novocain and mannitol for spinal anæsthesia.

### *Experiments by Admixture with Fresh Blood.*

*Expt. 1.*—Mannitol-quinine and a solution of quinine acid hydrochloride of similar alkaloidal strength were added to samples of fresh human blood to determine what difference, if any, could be observed on the quinine solutions coming into contact with it. Quinine acid hydrochloride was chosen as a salt readily soluble in water. As the amount of blood used was small, it was not expected that the results would be quantitative, but extraction of these blood and quinine mixtures with ether showed, confirming my previous work, that some of the quinine was actually present in the basic condition. In the case of quinine acid hydrochloride this is undoubtedly due to decomposition of the alkaloidal salt by the alkali of the blood.

*Expt. 2.*—The next step was to work on a somewhat larger scale, and for this purpose freshly drawn animal blood was used, the serum was centrifugalised off, and admixtures with mannitol-quinine and quinine acid hydrochloride solution of a like strength in quinine were added. Obviously, slightly different results would be obtained with entire blood, but for purposes of comparison and visibility serum was employed in this and the subsequent experiments. The blood serum was, of course, definitely alkaline to litmus, and it was noticed that incipient precipitation occurred in each instance on adding 1 c.cm. of the mannitol-quinine and of the quinine acid hydrochloride solution to 20 c.cm. of serum. I view this incipient precipitation in the light of the following suggestion :—

$$\text{Protein} + 2\text{NaHCO}_3 + \text{Quinine Ac.} \longrightarrow \text{Quinine Protein} + 2\text{NaAc.} + 2\text{CO}_2 + 2\text{H}_2\text{O}$$

On further addition of the two solutions to these amounts of blood serum the preparation with the mannitol-quinine addition naturally remained alkaline throughout, whereas in the case of the quinine acid hydrochloride solution about 3 c.cm. were sufficient to render the serum definitely acid.

*Expt. 3.*—The work was repeated on a subsequent occasion using larger quantities of fresh serum, the idea being to simulate to an extent what happens in vivo. There was no marked difference, so far as the precipitation was concerned, but ether extraction of the *clear fluids* (before precipitation) showed that approximately 33–38 per cent. of the quinine, added as quinine acid hydrochloride, was removable *as base*, but in the case of the mannitol-quinine as much as 75 per cent. of basic quinine was extracted from the serum.

*Expt. 4.*—In one instance excessive quantities of the quinine solutions—10 c.cm. to 60 c.cm. of serum—were added. After the addition of the 10 c.cm. of quinine acid hydrochloride solution the serum was definitely acid. In each case the serum was turbid, a precipitate forming after standing some hours. (It may be mentioned as interesting that a hydrochloric acid solution of the same strength in acid as the quinine acid hydrochloride solution, when added to the serum, did not cause any marked precipitation, whereas a 10 per cent. hydrochloric acid solution did.) The amount of the total quinine added which could be extracted as base in this experiment from the serum containing mannitol-quinine was 53·0 per cent., but with the quinine acid hydrochloride mixture was only 5 per cent. This hyper-acid experiment constitutes an extreme case ; the object was merely to determine what would happen in such an instance.

The matter is by no means concluded with these results, but the evidence from the various experiments conducted is clearly in favour of the use of such a preparation as mannitol-quinine. Experiments on hæmolysis would be of interest.

Medical men will, no doubt, grasp the trend of the whole investigation, and, if I may say so, its importance, because hitherto quinine salts injected have frequently caused actual necrosis, due no doubt to the *nature* of the salts used, and to the fact that actually a double chemical decomposition has to take place at the site of injection before the quinine can begin to act. Quinine is deposited, as such, at the site of the injection. Such quinine, I am told, could sometimes be cut out with the knife, and obviously could have no immediate antimalarial or other efficiency, because it had not dispersed through the tissues and was therefore incapable of action.

It has been shown experimentally, as described above, that when mannitol-quinine comes in contact with blood, a large proportion of the quinine (larger than in the case of quinine acid hydrochloride) is present in solution in the basic condition, and therefore in all probability is more readily absorbed. Whether the injection would show less deposition of quinine at the site of injection than the salts customarily used can only be determined by section-cutting, or, indeed, clinical use. There would certainly seem to be a distinct advantage in the administration of a basic preparation, since T. A. Henry and H. C. Brown [7] found that quinine base was considerably more active against free-living protozoa than the hydrochlorides, and J. A. Sinton [8] has stated that better results are given in malaria by the use of alkalis with the quinine. H. Acton [9] has also recorded the increased activity of the salts towards paramœcium in presence of alkali, and has concluded that, for injection, quinine base would be probably more efficient than the salts, and possibly non-irritant "if a means could be devised for injecting it in solution in this form."

### *Toxicity Experiments.*

Some experiments, kindly conducted for me by Major H. C. Brown, showed the toxicity to mice, intravenously, of the two solutions of quinine acid hydrochloride and mannitol-quinine, suitably diluted 12 or 24 times to be approximately the same—namely, about 1 c.cm. per kilo body-weight (equivalent to approx. 120 mg. of quinine per kilo). Mannitol-quinine was slightly the more toxic of the two. Experiments on mice with mannitol-quinine in the undiluted form could not be conveniently conducted, owing to the difficulty of measuring the small volume of the solution. I have been unable to trace data as to the toxic dose of boric acid intravenously in recent medical literature, hence, on this count alone, the results of these experiments are valuable.

It would labour the subject to incorporate the numbers of suggestions and experiments which have been made for several years past in my laboratories on the problem—the bulk of them fruitless. For example, any idea of employing a quinine salt and sodium bicarbonate on the lines of the cocaine and sodium bicarbonate injection, using every conceivable type of "protective," proved quite hopeless. Again, some weak acids, like glycine, had to be excluded by reasons of poor solubility of their salts.

*Glycerin instead of Mannitol.*—Glycerin has been mentioned as a possible substitute for mannitol. This appears to behave similarly, but a large proportion is needed, and on the whole the mannitol (though more expensive) seems to meet the requirements.

### *Conclusions.*

1. A formula for a reasonably concentrated solution of quinine salt (containing 12 per cent of quinine base) is given which contains the quinine virtually in the basic condition. 2. In view of the work of H. Acton, T. A. Henry and H. C. Brown, and others, the quinine in this form should be more potent. Though, as yet, no clinical trials on man have been made with it, my enthusiasm prompts me to publish this note. Perhaps other workers in the same field can make further suggestions. Animal experiments show that mannitol-quinine is practically no more toxic than a quinine acid hydrochloride solution of similar strength. 3. Mannitol-quinine may be suitable for hypodermic injection, and as such, or on further dilution, may be useful intravenously. 4. The solutions of the majority of quinine salts are distinctly acid, whereas mannitol-quinine has the advantage of being neutral, or only slightly alkaline. 5. Quinine salts (and mannitol-quinine) and other alkaloidal salts, on admixture with blood serum, yield the quinine and other alkaloids in basic condition to the serum, and mannitol-quinine shows a larger proportion, by experiment, of quinine base actually distributed. 6. It may be possible to utilise mannitol or glycerin on similar lines in the case of the borates of many other alkaloids.

PS.—Since sending this paper for publication, it has been noted that H. W. Acton and R. N. Chopra (*Indian Journal of Medical Research*, October, 1924) do not favour the injection of the salts of the cinchona alkaloids. They found that the hydrochloric acid radical of a cinchona alkaloidal salt causes œdema, irritation, and pain, and that the base, acting as a protoplasmic poison, causes death of the tissues. The neutral mannitol-quinine, described in my paper, obviates the effects produced by the very acid alkaloidal salts usually employed, and I am of the opinion that the quinine base in this preparation, being in solution, cannot be so destructive to the tissues at the site of injection, owing to its ready miscibility and diffusibility, as the suspension of the base tested by Acton and Chopra.

# ADMINISTRATION OF MORPHINE AND HEROIN.

## PRECAUTIONS TO BE OBSERVED BY THE PRACTITIONER.

THE Departmental Committee on Morphine and Heroin Addiction, appointed by the Ministry of Health in September, 1924, was asked

> "to consider and advise as to the circumstances, if any, in which the supply of morphine and heroin (including preparations containing morphine and heroin) to persons suffering from addiction to those drugs may be regarded as medically advisable, and as to the precautions which it is desirable that medical practitioners administering or prescribing morphine or heroin should adopt for the avoidance of abuse, and to suggest any administrative measures that seem expedient for securing observance of such precautions,"

and the reference was extended later to include consideration and advice

> "whether it is expedient that any or all preparations which contain morphine or heroin of a percentage lower than that specified in the Dangerous Drugs Acts should be brought within the provisions of the Acts and Regulations and, if so, under what conditions."

The Committee consisted of Sir Humphry Rolleston (chairman), Sir William Willcox, Dr. J. W. Bone, Dr. R. W. Branthwaite, Dr. G. M. Cullen, Prof. W. E. Dixon, Dr. John Fawcett, Dr. Adam Fulton, and Dr. J. Smith Whitaker, with Dr. E. W. Adams and Mr. R. H. Crooke (secretaries).

Section IV. of the report, which has just appeared (H.M. Stationery Office, 1*s.*), deals with the precautions to be observed in the administration of morphine or heroin. The position of a practitioner when using morphine or heroin in the treatment of persons who suffer from addiction to either of these drugs obviously differs in several important respects from that in which he is placed when using the drug in the ordinary course of his medical practice for the treatment of persons not so affected. Not only will the objects of treatment usually differ, but also the dangers to be avoided, and the precautions that are therefore necessary.

### *Precautions in the Treatment of Addicts.*

Morphine or heroin may properly be administered to addicts in the following circumstances—namely, (*a*) where patients are under treatment by the gradual withdrawal method with a view to cure; (*b*) where it has been demonstrated, after a prolonged attempt at cure, that the use of the drug cannot be safely discontinued entirely, on account of the severity of the withdrawal symptoms produced; (*c*) where it has been similarly demonstrated that the patient, while capable of leading a useful and relatively normal life when a certain minimum dose is regularly administered, becomes incapable of this when the drug is entirely discontinued.

*Gradual Withdrawal Method.*—In these cases the primary object of the treatment is the cure of the addiction, if practicable. The best hope of cure being afforded by treatment in a suitable institution or nursing home, the patient should, if possible, be induced to enter such an institution or home. If he is unable, or refuses to adopt this course, the practitioner must attempt to cure his condition by steady, judicious reduction of the dose. The general lines of the treatment, as carried out by practitioners of special experience, are described in the report. For success it is necessary that the patient should be seen frequently, be under sufficient control, and be in the care of a capable and reliable nurse. The practitioner should endeavour to gain his patient's confidence, and to induce him to adhere strictly to the course of treatment prescribed, especially as regards the amount of the drug of addiction which is taken. This last condition is particularly difficult to secure, as such patients are essentially unreliable and will not infrequently endeavour to obtain supplementary supplies of the drug. If, however, the practitioner finds that he cannot maintain the necessary control of the patient, he must consider whether he can properly continue indefinitely to bear the sole responsibility for the treatment.

When the practitioner finds that he has lost control of the patient, or when the course of the case forces him to doubt whether the administration of the drug can, in the best interests of the patient, be completely discontinued, it will become necessary to consider whether he ought to remain in charge of the case and accept the responsibility of supplying or ordering indefinitely the drug of addiction in the minimum doses which seem necessary. The responsibility of making such a decision is obviously onerous, and both on this ground and also for his own protection, in view of the possible inquiries by the Home Office which such continuous administration may occasion, the practitioner will be well advised to obtain a second opinion on the case.

*In Apparently Incurable Cases.*—These will include both the cases in which the severity of withdrawal symptoms, observed on complete discontinuance after prolonged attempted cure, and the cases in which the inability of the patient to lead, without a minimum dose, a relatively normal life appear to justify continuous administration of the drug indefinitely. They may be either cases of persons whom the practitioner has himself already treated with a view to cure, or cases of persons as to whom he is satisfied, by information received from those by whom they have been previously treated, that they must be regarded as incurable. In all such cases the main object must be to keep the supply of the drug within the limits of what is strictly necessary. The practitioner must, therefore, see the patient sufficiently often to maintain such observation of his condition as is necessary for justifying the treatment. The opinion expressed by witnesses was to the effect that such patients should ordinarily be seen not less frequently than once a week. The amount of the drug supplied or ordered on one occasion should not be more than is sufficient to last until the next time the patient is to be seen. A larger supply would only be justified in exceptional cases, for example, on a sea voyage, when the patient was going away in circumstances in which he would not be able to obtain medical advice. In all other cases he should be advised to place himself under the care of another practitioner, who should be placed in communication with his previous medical adviser in order that he might be informed as to the nature of the case and the course of treatment which was being pursued.

A practitioner when consulted by a patient not previously under his care, who asks that morphine or heroin may be administered or ordered for him for the relief of pain or other symptoms alleged to be urgent, should not supply or order the drug unless satisfied as to the urgency, and should not administer or order more than is immediately necessary. If further administration is desired, in a case in which there is no organic disease justifying such administration, the request should not be acceded to until after the practitioner has obtained from the previous medical attendant an account of the nature of the case. Requests from one practitioner to another for such information should obviously receive immediate attention.

### *Precautions in Ordinary Medical Practice.*

The evidence before the Committee would appear to indicate that there has been a recent diminution in the prevalence of morphine addiction, and that this is due to the operation of the Dangerous Drugs Acts in making it difficult to obtain the drugs except from or on the prescriptions of doctors. This enhances the importance of consideration of the precautions that are necessary in the use of these drugs in ordinary treatment, in order to reduce to a minimum the risk that a patient may develop a craving for them. These precautions are, the Committee thinks, well recognised among competent and careful practitioners in all branches of the profession, and the conclusions here stated, based on the testimony of medical witnesses, including representative general practitioners, may be regarded as expressing fairly the opinion of all members of the profession who have given the requisite attention to the subject.

Where the patient is suffering from organic disease for the treatment of which the drugs are necessary, the matter may be considered under two aspects, (*a*) cases in which the administration of morphine or heroin may be necessary for an indefinite period and in which the probability of a cure of the disease is remote (e.g., inoperable cancer and the like), (*b*) cases in which administration of the drugs is called for in order to deal with conditions which, though due to organic disease, may be expected to be of a more or less temporary duration (such as renal or biliary colic, &c.). In regard to class (*a*), since consideration of the possibility of the establishment of a craving cannot be allowed to influence the administration of such doses of the drugs as are considered necessary for the adequate treatment of the organic disease, it will be in those rare cases only in which there is some prospect of partial or complete recovery from the disease that any attention can properly be given, during the course of treatment, to such measures as are likely to mitigate or avert the risk of subsequent persistence of any craving which may have been produced. In respect of class (*b*), the employment of these measures becomes of paramount importance. They consist mainly in the substitution, when possible, of other drugs for morphine and heroin, in close supervision by the practitioner of the amounts used and of the frequency with which they are administered, and in withdrawal of the drug as soon as the necessity for its administration has ceased.

In stating the precautions to be observed in cases other than those referred to in the preceding paragraph, the Committee has in mind, particularly, those cases in which it is thought necessary to administer, say, morphine, in such doses, with such frequency and for so long a period as may be requisite, for example, for the relief of pain after surgical operations, or in cases of severe neuralgia in which the necessary relief cannot be obtained otherwise.

In cases in which it appears that the use of morphine or heroin may be thus desirable, it must first be considered whether the purposes of treatment can be substantially as well served by other drugs that do not involve the risk of addiction. Constant attention is necessary to adjust the dosage to the varying needs of the case. The intervals at which it is desirable to see a patient (not an addict) who requires the administration of morphine or heroin will necessarily be determined by the nature of the case. In cases of chronic disease requiring a more or less prolonged administration of the drugs, the patient need only be seen at such intervals as are appropriate on other medical grounds, but in cases such as renal or biliary colic, in which the necessity for the administration may cease at any moment, it may be important to see the patient more often than would otherwise be necessary in order to guard against the production of a craving.

The quantity supplied or ordered at one time for use by those nursing the patient should not ordinarily exceed what will be required before the patient is seen again. Where any discretion is given to nurses as to administration it should be strictly limited by prescription, and any change made in the treatment should similarly be stated in writing. The practitioner will realise that the responsibility for administration is entirely his, and cannot properly be delegated to any person not medically qualified. It is desirable also that the patient should not be informed of the name of the sedative drug employed; particularly inexpedient is the handing over to the patient of original packages containing morphine tablets, or the like, which bear on their labels a clear statement of the exact amount in each tablet. Hypodermic administration of the drug by the patient to himself is to be strongly deprecated.

all seemed to have been dumped upon France to relieve their home countries. This group has been costing 20,000 francs daily. The average age of the patients is 27, and the probable survival period is 30 years, so that the final cost will work out at somewhere about 50 million francs, even if the patients be placed in rural regions to reduce the expense.

There is no doubt that a certain number of them might leave the asylums, but before this can be done everyone of them will have to have a fresh mental examination. Dr. Roubinovitch, of Paris, who speaks Russian fluently, has offered his services as an alienist to the Minister of Hygiene and the Prefect of the Seine. Many of his compatriots cannot speak French, and obviously they have to be questioned in their own language. Probably this re-examination will take place, but the patients will first have to be collected into a single institution somewhere near Paris.

### *The Supply of Fresh Fish.*

Dr. Loir and Dr. Legangneux (both of Havre) have been studying the differences between fish preserved in melting ice, as is done on trawlers, and fish which has been kept in refrigerators, such as might be installed on larger ships which could go further afield to seas where fish is abundant. What we eat at present has been preserved in ice, but in a refrigerator it keeps the freshness that it had when it was caught. Here we have a question to look at from two points of view—the economic and the hygienic.

### *A Filter-passing Virus in Tuberculosis.*

Some interesting experimental research on a filter-passing virus in tuberculosis and on the transmission of infection through the placenta has been published by Dr. Arloing and Dr. Dufor, of Lyons. The agent which produces tuberculosis can not only occur in the bacillary forms in which it has long been recognised and studied, but can also be found in a form which is invisible and which is so minute that it passes through the porcelain of a filtering candle. This form of virus occurs especially in the tuberculous lesions of childhood (tuberculous adenitis, tuberculosis of the lung, and tuberculous meningitis). Inoculation into a guinea-pig of filtrate from such lesions produces tuberculosis of the animal in more than half the cases. Sometimes the guinea-pig dies in a state of extreme emaciation, and typical tubercle bacilli are found in the lymphatic glands without visible lesion. Sometimes, but more rarely, it dies of tubercle of the usual type. The authors have produced intra-uterine infection in the fœtus by inoculating the mother with filtrate containing invisible tubercle virus, and their experiments are, perhaps, important in their bearing on the vexed problem of hereditary tuberculosis.

### *Repopulation of France.*

A statement just issued by the Minister of Hygiene shows that the French birth-rate for 1924 was 19·2 per 1000 inhabitants, and that the infant mortality was 85 per 1000 live births. In 1913 the corresponding figures were 19·1 and 112. Infant mortality has thus distinctly diminished and the birth-rate is slightly more than holding its own.

The thirty-ninth French Congress on Ophthalmology will be held at Paris on May 10th. Information may be obtained from Dr. Onfray, 6, Avenue de la Motte-Picquet, Paris.

There will be a dermatological congress at Brussels from July 25th to 28th, at which there will be discussions on tuberculides, herpes zoster, purpura, syphilitic reinfection, superinfection and pseudo-reinfection, endocrine disturbances due to congenital syphilis, and the treatment of lupus and cutaneous tuberculosis.

From March 2nd onwards a post-graduate course in urological pathology and treatment is to be held at the Necker Clinic on Tuesdays and Fridays, at 4 P.M., under the direction of Prof. Legueu. Further details may be had from Clinique Urologique, Hôpital Necker, rue de Sèvres, Paris.

## DENTAL BOARD OF THE UNITED KINGDOM.

A MEETING of the Board was held on Feb. 10th, the President, Mr. F. D. Acland, being in the chair. It was announced that the name of Percy Ravenscroft had been restored to the Dentists Register from which it had been erased under Section 12 of the Dentists Act. The Board received from the secretaries of the Customs House a copy of Statutory Rules and Orders 1925, No. 1240, dealing with the sale of methylated spirits, from which it appeared that dentists have been placed on the same footing as medical practitioners under the regulations.

### *Public Education in Dental Hygiene.*

The Board adopted a report from the Dental Health Education Committee which dealt with business transacted since November last. Work in connexion with the dental health campaign has continued along the lines then laid down. New schemes of propaganda have not been initiated, but there has been a regular and increasing disposition to take advantage of the facilities offered, and it is clear that the Board's work is becoming widely known to organisations interested in public health. The Education Committee considers that the method of working through such bodies is justifying itself.

The main agents in publicity are cinema films, leaflets, and lectures, and the value of the cinema, both in giving actual instruction and in attracting the public to meetings, is becoming abundantly clear. More films have been asked for and, in conjunction with the National Baby Week Council, the Committee is preparing one which deals with the care of the mouth of the expectant and nursing mother and the infant. Requests for some 80,000 leaflets have been received since the last report; demands have been made by various insurance committees for large supplies for distribution to insured persons, and it is hoped that the approved societies will coöperate in distributing the Board's literature more widely. The offer to provide private practitioners with leaflets has evidently been appreciated, for some 500 dentists have applied for them.

Amongst the organisations with which the Board is cooperating are the Industrial Health Educational Council, through whose good offices the Board's lecturers are gaining access to the industrial classes in certain parts of Scotland; the Girl Guides; the National Council for Health, Maternity, and Child Welfare; and the National Federation of Women's Institutes. It is hoped that negotiations with the Federation will result in health lecture tours, to be arranged by the British Red Cross Society.

Other forms of propaganda have not been neglected. Progress has been made in the collection of the proposed dental health exhibit. A book for the instruction of teachers is in an advanced stage. Satisfactory publicity has been obtained in the press. The Committee believes that its efforts have already met with a notable degree of success and that serviceable work is being done at no undue cost by methods which are satisfactory to the dental profession.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 13TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox 253 (last week 390); scarlet fever, 1613; diphtheria, 1150; enteric fever, 43; pneumonia, 1352; puerperal fever, 62; cerebro-spinal fever, 15; acute poliomyelitis, 6; encephalitis lethargica, 61; dysentery, 6; ophthalmia neonatorum, 104. There were no cases of cholera, plague, or typhus notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there were 2 (1) deaths from enteric fever; none from small-pox; 83 (19) from measles; 14 (2) from scarlet fever; 60 (4) from whooping-cough; 26 (9) from diphtheria; 49 (10) from diarrhœa and enteritis under 2 years of age; and 90 (16) from influenza. The figures in parentheses are those for London itself.

# Public Health Services.

## MENTAL HOSPITAL REPORTS.

THE fifty-fifth annual report of the *Glengall Hospital, Ayr,* records a drop of 23 in the number of inmates since the end of 1924. The superintendent reviews the figures for 30 years past and shows that the admission rate is much the same for both sexes to-day. The recovery rate was 31 per cent. for men and 57 per cent. for women, although the majority of women admitted were in a gravely exhausted state. There was some slight improvement in the physical state of the admissions last year on the male side, but on the whole the standard of physical health has steadily deteriorated for some years past, as many as 70 per cent. of the women and 12 per cent. of the men being classed as "seriously exhausted" on admission. The death-rate was 14 per cent., showing a steady increase during the last decade; half of the fatal cases were over 60. The general health of the inmates has been good, and there have been no epidemics. The hospital has a few voluntary boarders, but unfortunately there are still a number of mentally defective children who should really be in an *ad hoc* institution. Forty-one per cent. of the nurses and 33 per cent. of the attendants have obtained the certificate of the Royal Medico-Psychological Association.

The report of the Inspector of *Hospitals for the Insane in Queensland* for the year 1924 is just to hand. There are three large hospitals in the State. That at *Goodna* has 1400 patients and, of the 400 cases admitted during 1924, nearly half were suffering from the manic-depressive psychosis. There was a recovery rate of 52·6 per cent. on the admissions, the second highest rate for 16 years. The rate represents a high proportion of recoveries in the province, since curable cases of transient and incipient mental disease are received in the mental ward of the Brisbane General Hospital and so are not included in the statistical figure. The death-rate was 10·4 per cent. Senile decay was the fatal cause in a quarter of the cases, while no fewer than 12·8 per cent. died of general paralysis. Between 600 and 700 patients are employed about the buildings and grounds, chiefly in ward work and gardening or farming. At *Toowoomba* there are just over 1000 patients. Here also the manic-depressives form a large proportion (33·7 per cent.) of the total admissions during the year, but only one case of general paralysis was admitted. The recovery rate was 32·5 per cent., a lower figure than usual owing to a large number of senile dements and irrecoverable cases from the epileptic home at Willowburn. The death-rate reached the low figure of 3·8 per cent. This is the only mental hospital in Queensland that has no cinematograph apparatus. The *Ipswich Hospital* has only 450 patients, as it is a reception house for transfers from other hospitals, mainly for chronic cases from Goodna. The recovery rate is therefore low—18·2 per cent. The death-rate was 3·1 per cent. As many patients as possible are usefully employed about the hospital. There are also two reception houses, that at *Rockhampton* being only a half-way house for those arriving too late to proceed straight to Brisbane, while the *Townsville* House receives patients for observation and treatment before they go on to Goodna. About 100 such cases passed through during 1924, and 16 of them were discharged recovered. The total number of certified patients in the State at the end of 1925 was 2902, showing an increase of 25 on 1923, a proportion of 3·17 per 1000 of the total population. This corresponds with the figure in other States, the lowest being 2·21 in South Australia and the highest 3·81 in New Zealand. There is a State mental nursing certificate obtainable by examination, and a large proportion of the nurses hold this; 62 per cent. at Goodna, 44 per cent. at Toowoomba, and 72 per cent. at Ipswich.

*"Audi alteram partem."*

## PUNCTURED WOUNDS OF THE FINGER.

*To the Editor of* THE LANCET.

SIR,—From time to time the loss of a member of our profession is recorded as a result of a punctured wound of the finger, received during the performance of a post-mortem examination or of an operation on some acutely septic condition. In other cases not recorded irreparable damage has been done to the finger or hand sufficient to limit considerably any future work or at any rate create a serious handicap.

There were two lessons learned, or rather I should say impressed on us, during the war. The first was that excision of a wound was the best means by which to avoid a spread of sepsis, and provided this was performed early, success was met with in a large number of cases. The second was that temporary complete immobilisation of the limb, which gives the natural defences of the body the best condition under which to act, was a most valuable factor in helping to localise the results of an infection.

It is not always an easy matter to apply these two principles in civil life, and yet one cannot help feeling that adherence to them might be the means of avoiding some disasters. In my opinion a puncture wound of the finger received when there is a risk of infection should be immediately excised (after excision the wound may be closed) and the limb splinted.

It is in the very early stages only that these infections can be dealt with successfully, and though such treatment may often be considered excessive, the few days of real inconvenience it entails must be compared with the dire results that may otherwise follow. I am, Sir, yours faithfully,

London, Feb. 17th, 1926. F. D. SANER.

## THE ADMINISTRATION OF CARBON DIOXIDE IN ANÆSTHETICS.

*To the Editor of* THE LANCET.

SIR,—The administration of mixtures of carbon dioxide and oxygen in conjunction with general anæsthetics has been practised in America for a number of years. More recently, since such mixtures are now obtainable commercially in this country, it would seem that yet another cylinder must be included in the already sufficiently cumbersome equipment of the anæsthetist; for of the value of carbon dioxide there can be no doubt. It is probable that some of the good results obtained in nitrous oxide-oxygen anæsthesia are attributable to conservancy of carbon dioxide by re-breathing. The same contention may hold good, to a lesser extent, in "*perhalation*" ether administration.

On the other hand, it is just possible that some of the pallor and feeble respiration occasionally associated with open chloroform anæsthesia may be due to carbon dioxide deficiency. Prof. Yandell Henderson has already dealt with carbon dioxide deficiency as a factor in the causation of shock. In endotracheal insufflation anæsthesia, where re-breathing is not practicable, the occurrence of apnœa is not uncommon. When associated, as it usually is, with light anæsthesia, this troublesome factor can be responsible for muscular rigidity and delay in obtaining the necessary depth of anæsthesia. Under such conditions it is quite possible for cyanosis to be present, even when oxygen alone is being driven through the catheter. The judicious use of a mixture of 10–15 per cent. carbon dioxide with oxygen in these cases is attended by the immediate re-establishment of the respiratory excursions and consequent attainment of the requisite depth of anæsthesia.

At the end of an operation conducted under open ether the exhibition, in a gas-bag, of a similar mixture promotes de-etherisation and lessens post-operative nausea. This practice would seem to be of definite value at the end of a high abdominal operation, in the course of which the movements of the diaphragm are liable to be hampered. By assisting in the early re-establishment of diaphragmatic activity the mixture may well remove the tendency to stagnation at the pulmonary bases and help in the prevention of post-operative pneumonia.

In private practice the most convenient form in which to carry carbon dioxide for occasional use is the well-known "sparklet bulb." An ordinary fine adjustment valve can now be obtained from Messrs. Allen and Hanburys, Ltd., fitted with the necessary device for holding and puncturing the bulb. The gas is released into a small football bladder, from which it can be transferred as required to a gas-bag and mixed with oxygen in the proportions desired. Where greater accuracy is essential a water sight-feed fulfils the purpose.—I am, Sir, yours faithfully,

I. W. MAGILL, M.B., B.Ch. Belf.,
Assistant Anæsthetist, Westminster Hospital.

Feb. 20th, 1926.

## LORD LISTER'S BIOGRAPHY.

*To the Editor of* THE LANCET.

SIR,—A German translation of Sir Rickman Godlee's biography of Lord Lister has been published, which claims to be "the only authorised translation." It was only "authorised" on condition that it should be approved by him before publication, and this condition was not fulfilled. As his executrix I desire it to be known that neither he nor his representatives are in any way responsible for the accuracy of it.

I am, Sir, yours faithfully,
JULIET M. GODLEE.

Whitchurch, Oxon, Feb. 16th, 1926.

## A LUNG SPLINT.

*To the Editor of* THE LANCET.

SIR,—Under this title Dr. R. C. Wingfield has furnished a valuable contribution to the treatment of phthisis in your issue of Jan. 2nd. He points out the advantage of "limiting the movement of the diseased parts of the lung by even so little as 1 cm." and describes the method by which he attains this end.

On the desirability of limiting movement in the treatment of any lesion of the lung substance, I am entirely at one with Dr. Wingfield, a little limitation effected by some form of lung splint being at one end of the scale, and complete collapse of the lung by artificial pneumothorax at the other. The respective techniques of thoracoplasty and artificially induced pneumothorax, as recognised therapeutic measures, are more or less worked out, but the best method of restricting the movements of the lung by some form of lung splint still remains sub judice. I discussed the whole question of lung immobilisation in a paper entitled De la Compression du Poumon dans le Traitement de la Tuberculose Pulmonaire, read at the Paris Congress of Tuberculosis in October, 1905.

The point I wish now to emphasise is that the objective of treatment is not only to limit the movements of respiration but, furthermore, to relax the continuous tension on the periphery of the pulmonary lesion. We all know that an ulcer of the leg—a lesion of two dimensions only—will not commence to heal till the tension is taken off its edges. Hence, it may be assumed, a fortiori, that a cavity of the lung, which is a lesion of three dimensions, will not heal till the tension is taken off its walls. Thus, in dealing with pulmonary lesions, the problem is how to relax the peripheral pull continuously exercised by the chest wall on the lung substance—a pull which in health keeps the air cells distended while in disease it is opposed to the process of repair. Seeing that the disease is situated in the lung tissue and that the pull is exercised in every direction at its periphery, the solution of the problem is this: relaxation of the pull can be effected only by compression of the lung substance.

Compression of the lung may be either complete or relative—complete, when the lung is collapsed by effusions or pneumothorax, either spontaneous or induced—relative, when the chest cavity is reduced in size, either by natural processes of repair, by thoracoplastic operations, or by some method of chest compression. In collapse, when the lung tissues are generally and completely relaxed, the diseased area is theoretically under the best conditions for healing—an a priori conclusion confirmed by the salutary effects observed in pneumothorax, whether spontaneous or artificially induced. But there is also evidence to show that partial relaxation of the lung tends to promote healing in the diseased portion. And, apart from thoracoplastic operations—most valuable in certain cases—it remains to consider by what other means the lung tissues may be partially relaxed. This can only be effected by reducing the capacity of the thoracic cavity. Nature's methods of compassing this end are: 1. The encroachment of neighbouring organs—viz., the opposite lung and the abdominal organs—on to the domain of the diseased lung. 2. The falling in of the chest wall. 3. The development of bands of fibrous tissue radiating in many directions from the diseased area. These by their retraction not only tend to relax tension on the diseased area by their pull on neighbouring portions of healthy lung, but, when adherent to the parietal pleura, they pull in the chest wall.

How, then, can we aid Nature in this her task of reducing the size of the thoracic cavity? The cubic capacity of the chest varying with each respiratory movement, the idea of maintaining the chest cavity at its minimum suggests itself. And while it is impossible to abolish all respiratory movement, much can be practically accomplished, and, furthermore, the minimum capacity may be progressively reduced by the continued maintenance of pressure.

Where and how should this pressure be applied? In order to determine this, it is necessary to consider certain features of the thoracic cavity. It is cone-shaped, with its apex or dome upwards. The dome is less amenable to pressure than the base, being to a great extent sheltered by the shoulder girdle. The base admits of a much wider range of movement than the dome. The lung completely fills the chest cavity; in health it is uniform in structure throughout and fills uniformly with air when subjected to the peripheral pull of the chest wall, much as a sponge does when immersed in water.

With these structural and physical features in mind, let me endeavour to compare the effects of pressure applied at the apex of the lung and at the base, respectively. Pressure at the apex, by whatever method applied, to be effective must first double inwards and downwards the dome of the thoracic cavity. It will then act on the apex of the lung, tending thereby to relax the peripheral pull. But, as the general direction of the pressure is downwards, its effect must be to push downward the apex of the lung, so that a point at any level of the apex before the application of pressure must, when pressure is applied, be displaced downward in relation to the thoracic cavity. At its new level the circumference of the thoracic cone is greater and the power of the peripheral pull proportionately increased; so that the relaxation gained by direct pressure is counterbalanced by increased peripheral pull. Assuming, then, that relaxation of peripheral pull on the diseased area is the objective of treatment in pulmonary lesions, I conclude that, a priori, one cannot anticipate the best results from pressure applied at the apex.

To turn now to pressure applied at the base by means of a constricting band round the lower part of the thorax on the affected side. This not only limits the range of the respiratory movements but it thrusts the whole lung upwards, so that each point of its periphery is somewhat higher in relation to the thoracic cavity than it was before the application of the constricting band. And, being higher up, the lung occupies a narrower portion of the thoracic cone and, consequently, there is a general relaxation of the peripheral pull. Meanwhile, the apex of the lung is crowded into the pleural dome, the narrowest and most immobile part of the thoracic cavity, and, in that position, it is subject to a minimum degree of movement and a maximum degree of relaxation.

The application of this method is very simple, and can be carried out equally well at home as at an institution. The material used is 1½ in. adhesive strapping. Of this I cut six strips, long enough to surround the lower half of the thorax, just overlapping the spines of the vertebræ behind and the middle line of the epigastrium in front. The edges of the strips I snip, so that they may adapt themselves better to the contour of the surface. The first strip is applied firmly over the tenth dorsal spine and follows a slightly descending line to about the middle of the epigastrium. While applying it I direct the patient to breathe out forcibly and I pull it round firmly, fixing it during expiration; the second strip, just overlapping the upper margin of the first, I apply in the same way; the third strip I apply from below upwards, so that it crosses the first two and acts as a check to prevent them from slipping; the fourth and fifth slips are applied in series with and above the first and second and the sixth is applied as a check parallel to the third. In one or two cases I tried antero-posterior strips, passing over the shoulder and interlacing with the horizontal strips, but this I abandoned, both on practical and theoretical grounds. The strapping is changed about once a week, and should be carefully removed with the aid of spirit or turpentine, so as to safeguard the skin from injury. The treatment must be continued for a considerable period. The maximum over which I maintained it was two years and, while extraordinarily rapid healing took place in several cases, some benefited but slightly and others not at all.

The treatment is of most use in the common case of disease commencing at one apex, but I have had favourable results from its use where both lungs were affected. Moreover, it possesses certain advantages over the collapse method, so that it need not be used only to "avoid drastic procedure" but because, in suitable cases, it is better.

I am, Sir, yours faithfully,
STUART TIDEY, M.D., M.R.C.P.

London, Feb. 12th, 1926

---

## INTRAVENOUS SOMNIFENE ANÆSTHESIA

*To the Editor of* THE LANCET.

SIR,—Dr. R. K. Lambert's paper on the aliphatic compounds in general anæsthesia in your issue of Jan. 16th, and Mr. E. R. Flint's note on hedonal anæsthesia in that of Jan. 30th, show how unceasing is the search for the ideal method of anæsthesia. Recently, in France, the experimental and clinical researches of Fredet and his associates on the use of somnifene in intravenous injection for surgical anæsthesia prove that by the use of this preparation general anæsthesia may be reduced to a minimum—in some cases it may be eliminated. The effect of somnifene is somewhat similar to that of hedonal as described by Mr. Flint, but the patient becomes unconscious more rapidly, usually about three to four minutes after the injection is begun. Fredet's interesting researches demonstrate that the seat of action of somnifene is chiefly in the nerve centres; its effect on the liver and kidney is extremely small. He further found that in the commercial product of this name there are two constituents, one with a slow and needlessly prolonged anæsthetic effect. He has eliminated this body and now employs only the other—viz., allylisopropylmalinurea—whose action is rapid and more transient.

To obtain surgical anæsthesia with this product it must be combined with morphia, or with morphia and scopolamine. In some cases nothing more is needed, but generally a small amount of a general anæsthetic is used to make and to close the incision. The technique of Fredet's method is as follows:—

(1) A hypodermic injection of morphia is given, varying from a minimum of 1 cg up to 2 cg as a maximum. It is advantageous to associate scopolamine with the morphia in doses varying from ¼ mg. as a minimum up to ½ mg as a maximum *according to the weight of the patient, and whether his general state is cachectic or satisfactory.*

(2) Twenty minutes later as a minimum interval, or 45 minutes as a maximum, after the morphia-scopolamine injection, the intravenous injection of allylisopropylmalonylurea is made in a vein at the bend of the elbow with a fine needle and *very slowly;* three minutes at least should be spent in the injection. The dose is calculated *according to weight, age, and the general state of the patient.* Generally in fairly robust adults 1 cg. *per kg.* of body-weight is used, never passing 0·07 g. Personally, we have never passed 0·08 g. In aged or cachectic patients 0·04 or 0·03 g. should be enough. Ampoules of the drug may be obtained containing 0·01 g. in each cubic centimetre of water.

(3) *Five minutes after the intravenous injection a small* amount of chloroform or ether may be *given to permit the* incision being made about ten minutes after the intravenous injection. During the operation the general anæsthetic can often be dispensed with, to be resumed should the patient move and at the end to facilitate the suture of the wound.

This technique in practice is extremely simple, the anæsthesia is excellent, post-operative vomiting very rare. Patients awake four or five hours after operation to fall asleep quietly again. Excitement, which was frequently observed after somnifene anæsthesia when first used, is often quite absent with the latest preparation. I have used this anæsthesia in certain cases for over 18 months and, though it has not replaced routine methods, it is my choice in two types of cases—when the patient is a bad risk from pulmonary complications or from probable hepatic and renal insufficiency, and again when we are certain the operation must be prolonged. Thus I have used it in most types of gastric operations, gastro-enterostomy, gastrectomy, Balfour's operation, pyloroplasty and duodeno-jejunostomy, colectomy, and the prolonged operations needed for the case of gastro-colic fistulæ. In the tedious operation for large ventral hernia in a bronchitic patient and in exploratory operations when cancer is inoperable it has served me well. In several cases of gastro-enterostomy in most debilitated patients, by the addition of some local anæsthesia of the wall no general anæsthetic was required. In a case of colectomy of the sigmoid for a ring carcinoma neither local nor general anæsthesia was employed, the patient slept deeply, never resenting the inevitable drag of the mesentery during mobilisation of the descending colon which was anastomosed to the rectum by Mayo's tube method. He never vomited afterwards; the pulse never passed 100.

Fredet's researches and a list of cases in which this anæsthesia was employed are fully detailed in the *Bulletins de la Société Nationale de Chirurgie* for July, 1924, and March, 1925. More recently he has published (*Paris Médical*, Dec. 5th, 1925) a useful résumé of his work after an experience of about 200 cases.—I am, Sir, yours faithfully,

IAN MACDONALD, M.D.

Huelva, Spain, Feb 10th, 1926

## SELECTION OF COD-LIVER OILS FOR MEDICINAL USE.

*To the Editor of* THE LANCET.

SIR,—In the joint inquiry upon cod-liver oil, conducted by Prof. J. C. Drummond and myself, I was mainly responsible for the section dealing with the Newfoundland oils and with the relation of the sexual condition and age of the cod to the potency of the liver oil. I feel, therefore, obliged to comment on the article by Prof. E. Poulsson in THE LANCET of Feb. 6th (p. 320), in which he criticises certain statements made by Prof. Drummond in the issue of Sept. 26th, 1925. As I did not see Prof. Drummond's article until it appeared in print, I do not hold myself responsible for everything stated therein.

Prof. Poulsson is quite right in asserting that the sexual condition of the cod during spawning has no bearing on the activity of the oil, as was shown by my colleagues and myself, and I feel gratified that this work has been confirmed by our Norwegian colleague. It is difficult to interpret Prof. Poulsson's figures on the relative tests of Newfoundland and Norwegian cod-liver oils without a fuller description of the method employed by him. In our own work, with numerous samples of Newfoundland oils originating from different localities and from different seasons, the minimum growth-promoting dose as tested by the method of Zilva and Miura [1] was found to vary from 1·3 mg. to 1·6 mg. On the other hand, a much greater variation was found in the growth-promoting potency of the Norwegian Lofoten oils. Whether this variation was accidental or not, time will prove. At present neither the work of Prof. Poulsson nor of Prof. Drummond and myself can supply a definite answer.

It has now become necessary to reconsider the method previously employed for estimating the fat-soluble vitamins in the light of the new discoveries made in this field of research since the inception of the cod-liver oil inquiry. We are faced with the problem whether the high potency of individual cod-liver oils, as observed by employing "growth" criteria, should be referred to their content of vitamin A or of the antirachitic vitamin D or to the joint effect of both principles. If at the present time I desired a potent cod-liver oil, I should endeavour to procure a Newfoundland oil, not because it hails from a British possession, but because from the scientific information available it is of high and *uniform* potency as judged by the older methods employed for testing.

I am, Sir, yours faithfully,
S. S. ZILVA.

The Lister Institute of Preventive Medicine.
London, S.W., Feb 16th, 1926.

## TRANSFUSION OF WHOLE BLOOD.

*To the Editor of* THE LANCET.

SIR,—Encouraged by Dr. Dyke's letter in your last issue reopening the subject of blood transfusion, I feel that several further points might well be raised. In the leading article in THE LANCET of Jan. 23rd it is stated that Dr. Platt finds that "reactions never occur" with defibrinated blood, and that "the minor reactions are all due to citrate." Neither of these statements is made in my paper (which appeared in that issue), as any careful reader may find out for himself. In my paper as drafted the question of the origin of the reactions was more fully dealt with, but this had to be cut down for publication.

With regard to Dr. Dyke's letter, the pathologists have repeatedly warned us of minor agglutinins, but, as pointed out in the same leading article, these have never seemed to be of much importance practically. No doubt a careful adherence to Dr. Dyke's technique of blood testing might eliminate some of the very infrequent and mild reactions which undoubtedly may occur with whole (uncitrated) or with defibrinated blood. (Incidentally, I do not like the term "whole" applied to citrated blood, which is, of course, deficient in available calcium.) However, as last week I had to test no less than 11 relations and friends of a patient before finding a Group IV. donor, I was glad to be content with a "two-minute" test.

I quite admit that I have omitted to take precautions against minor agglutinins, but Dr. Dyke, on the other hand, has disregarded entirely the scientific evidence that citrated blood may be toxic even to the individual from whom it was taken. References to this may also be found in my paper. If we agree that the problem of the cause or causes of reactions is still open to controversy, the only evidence acceptable must therefore be of a practical nature, and come from those who have had experience of the technique and results of both methods. I very much doubt if any one who has had that experience would ever go back to citration.

With reference to Dr. H. H. Moll's paper (in your issue of Jan. 23rd), though I am interested in his ingenious method, if he will try applying "a fair amount of pressure to maintain a steady flow of blood through the very fine needle" into a test-tube he will find that on centrifuging a good deal of hæmolysis has taken place. I have often wondered whether the injection of partially hæmolysed blood is not another possible cause of reactions.

I am, Sir, yours faithfully,
Sheffield, Feb. 20th, 1926. ROBERT PLATT.

*** We regret having attributed to Dr. Platt an opinion which he wishes to disown. The sentences in our leading article were intended to summarise his attitude, as the absence of quotation marks indicated. We seem, however, to have misinterpreted his intentions, and it will make the position clearer if we now reprint his actual words: "That the reactions are due to the citrate and not to the many other factors which have been suggested is shown by the fact that such reactions practically never occur when whole blood is used—and as I hope to show later, when defibrinated blood is used . . ." The difference between Dr. Platt's opinions and our restatement of them seems to be very small.—ED. L.

## CRIMINAL OFFENCES AND PROSTATIC ENLARGEMENT.

*To the Editor of* THE LANCET.

SIR,—I should be glad to correct two material errors in the last sentence of your otherwise accurate summary of my paper at the Medico-Legal Society on Feb. 16th; because I never suggested that in *most* cases the guilty person should be placed under the care of relatives, or that this was a function of the Procurator-Fiscal in Scotland.

My plea was that in certain cases only—namely, where the man had led an ordinary decent life up to the age of 60—the existence of prostatic enlargement in conjunction with symptoms might be advanced in mitigation of consequences; that in cases of indecent exposure the medical evidence, together with an undertaking by relatives that the guilty person would be placed under supervision and medical treatment, might lead the Procurator-Fiscal in Scotland to stop criminal proceedings; that the same evidence in England might lead magistrates to have the guilty person bound over; and that in all more serious cases medical treatment should be undertaken in prison, unless insanity was established within the limits of the McNaghten judgment.

It is certainly not the function of the Procurator-Fiscal to supervise the conduct of such persons, and except in the simplest cases, whose behaviour resembles senility more than vice, no relaxation of the criminal law was advocated.

I am, Sir, yours faithfully,
HALLIDAY SUTHERLAND.
Wimpole-street, W., Feb. 20th, 1926.

## MEDINAL.

*To the Editor of* THE LANCET.

SIR,—The fatal case of poisoning by medinal so graphically described in your last issue attracted my attention, because this preparation of veronal has, for some years, been my favourite drug in troublesome insomnia. No estimate was apparently made of the amount of the fatal dose, but it was obviously enormous even for one who was the victim of a veronal habit. Dr. Stolkind's article conveys an ominous warning of the mental and physical degradation which awaits those who become addicted to di-ethyl-malonyl-urea, under any guise or nomenclature. But as long as hypnotics have a part to play in therapeutics, it seems to me very difficult to secure a drug which is safer than this one, which

---

[1] Biochem. Jour., 1921, xv., 654.

I *prefer to use in the form of medinal.* The drug is certainly powerful as a hypnotic, but in my experience of it, it is innocuous to the digestive, circulatory, respiratory, and nervous systems if used in medicinal doses. The drug is obtainable in various forms, but I have come to rely on the medinal preparation because of its rapidity of action. It seems to me that the moral of this unfortunate case lies in its *social aspect, and that the important therapeutic value of* the drug is in no way compromised by the interesting report of Dr. Stolkind.

I am, Sir, yours faithfully,

J. SNOWMAN, M.D.

Brondesbury, N.W., Feb. 22nd, 1926.

*** We are glad to publish Dr. Snowman's letter. With reference to Dr. Stolkind's note which appeared in THE LANCET last week, it has been pointed out to us by Messrs. *Schering, Ltd.,* that, while medinal, a scheduled poison, will, of course, be harmful if taken in grossly wrong doses, it possesses certain pharmacological characters contradicting the conclusions arrived at in the article. The opinion of Dr. Mackenzie Wallis, expressed during a discussion on insomnia at the Bath meeting of the British Medical Association, was to the effect that "sulphonal, veronal, and medinal in ordinary doses had no effect whatever on the functional activity of the liver and kidneys nor was there any effect on general metabolism . . . . all three drugs were rapidly excreted and showed no evidence of cumulative action." It is claimed for medinal that, being extremely soluble, it is rapidly absorbed and eliminated, cumulative effects being thereby obviated. —ED. L.

# Obituary.

## MEREDITH B. R. SWANN, M.D. CAMB.,

### DEMONSTRATOR OF PATHOLOGY IN THE UNIVERSITY OF CAMBRIDGE.

WE alluded last week to the tragedy of Dr. Swann's early death. He performed a post-mortem on the morning of Feb. 6th on a patient suffering from lymphatic leukæmia, who had died with a high temperature probably due to a terminal infection. Swann sustained a small punctured wound through a rubber glove, the wound being at the tip of the middle finger of the left hand—it was thought to be due to a sharp tooth encountered whilst removing the larynx. No measures were taken until afterwards, when picric acid was applied, but about bedtime Swann himself made a small incision with a *razor as the finger* was painful, and at 4.30 A.M. on Feb. 7th surgical advice was taken. The temperature was then about 102°F. and the finger was at once laid *open,* the puncture excised, and antistreptococcus serum injected. Some slight axillary *tenderness* was noticed, and later in the day a large dose, 100 c.cm., of serum was given (pure *streptococcus having been found* in smears and early culture) and an extensive incision was made over a *reddened site in the* upper arm. The temperature on the 8th being about 100° and the axilla quiet, it was *hoped that the* mischievous process was under control; but on the 10th the temperature was higher and a wide clearance of inflamed glands was made from the axilla, at the apex of which a few drops of pus were discovered. This was the only pus seen in the illness, the subsequent history of which was chiefly one of incisions for spreading skin infection of the clinical nature of erysipelas. This occurred on the left side from the neck to the groin, and, although improvements at times followed, death from toxæmia took place on Feb. 16th.

Meredith Blake Robson Swann was born on July 20th, 1893. He was the son of Frederic Swann, at one time headmaster of Ilkley Grammar School and subsequently a member of the staff of the *Times.* Educated at Dulwich College, he was elected *to a* scholarship at Gonville and Caius College, and in 1914 was placed in the first class of the Natural Sciences Tripos. He completed the medical curriculum at King's College Hospital, and after acting as house physician and casualty officer was gazetted as surg.-lieutenant to H.M.S. *Bacchante.* He served in the Royal Navy until after the conclusion of the war, and in April, 1919, returned to England and was shortly afterwards appointed demonstrator of pathology in the University of Cambridge. In March, 1923, he was admitted to a Fellowship at Caius and in *the same year he was awarded the Raymond Horton* Smith prize, which is given for the best dissertation submitted for the degree of Doctor of Medicine.

Swann from the beginning showed that his return to a career of research was justified. He was greatly attracted by the work for which he had exceptional gifts. He was a brilliant and successful teacher, and both in the Department of Pathology and at Caius, where he became supervisor of medical studies, his exceptional ability was expended to its full extent for the benefit of his pupils. He was sincerely interested in teaching, and he never failed to interest the men whom he taught. In the selection and preparation of material *for class-work he held no expenditure of time or pains* too great to secure results which satisfied his judgment. He expected a high standard from the men whom he taught and he never spared himself in helping and encouraging others to do their work well. As supervisor of medical studies he exerted a great influence on the large number of students who came to him for guidance and advice. He took a prominent part in devising and carrying out the new courses in general pathology for Part II. of the Natural Science Tripos and was personally *responsible for a well-planned* schedule in experimental morbid histology.

Already his published work demands attention—it was concerned with the *germination period of bacterial* spores and with the effects of X rays on the functions *of tissues and organs. More recently he had taken* a very active interest in histology and was keenly studying *methods for the* production and demonstration of the minute anatomy of inflammation and necrosis.

Dr. Swann married in 1917 Marjorie, daughter of Mr. Alfred H. Dykes, of Beckenham, by whom he had three children, and the deepest sympathy for them in their loss is felt by all. His colleagues and his many friends were devoted to him and he was universally popular among his pupils; his death has caused a gap in university circles which will be hard to fill, and his memory will long abide at the centre of his work.

## JAMES FAIRLIE GEMMILL, M.D., D.SC. GLASG., F.R.S.

BY *the death of Dr. J. F. Gemmill,* professor of natural history, University College, Dundee, the College has suffered a severe loss, as although he had only served it for six years his influence and teaching had already made themselves felt.

James Fairlie Gemmill had a brilliant record as student; in arts, in classics, and in philosophy he gained most of the prizes open to him, and in medicine his record was much the same. It was his ideal to take up scientific research. From the *first he was* attracted by marine biology, and after graduation his first few years were spent in *equipping himself* by study in the chief European marine laboratories. Returning to Glasgow *University, he acted* as assistant and later as lecturer-assistant in the anatomical department, and on *the establishment* of the new department of embryology was made lecturer in embryology with full *charge of the laboratory.* To a large extent, however, his bent was still towards marine biology. *Largely through his efforts* the West of Scotland Marine Biological Association was formed, and later the *marine laboratory* at Millport. In both these institutions he was the leading spirit. The *material obtained from* Millport gave him continuous problems for research and his steady flow of original *articles showed that he* utilised his opportunities to the full. His eager enthusiasm resulted in widespread *interest in marine biology,* and the summer course in Millport attracted large classes. His promotion to

University College, Dundee, came in due course, and his influence there was soon felt. Again he had the congenial task of building up a local interest in natural history, and well he performed this task. He instituted popular science lectures in University College and his vast output of original work was recognised to be of high merit. His monograph on the Teratology of Fishes and his important researches on marine worms, the development of echinoderms, and the embryology of cœlenterates put him in the first rank of British zoologists. Gemmill's teaching was attractive and his influence lasting. In his relationship to his fellow men he was very fortunate in his happy gift of friendship. His wide knowledge, his kindly attitude, and his somewhat shy manner endeared him to all ranks and conditions of men. There was much sympathy when it was learned at the beginning of the winter session that he was obliged fo ask for leave of absence on account of ill-health. A prolonged holiday had helped but not cured him. He found it impossible to resume teaching, but was continuing with some of his research work at the time of his death. He was elected F.R.S. in 1924.

## HUGH JONES ROBERTS, M.D. DURH., F.R.C.S. EDIN., D.L., J.P.

IN his sixty-fourth year Colonel H. J. Roberts, of Pen-y-Groes, near Carnarvon, has died at Southport, and by his death Carnarvonshire has lost one of its outstanding personalities. Hugh Roberts was the eldest son of the late Dr. Evan Roberts, whose practice he and his brother carried on at Pen-y-Groes. He qualified from Guy's Hospital, London, as M.R.C.S. and L.S.A. in 1885, and in 1907 took his M.D. degree at Durham. Four years later he became F.R.C.S. Edin. In his own county Dr. Roberts was a magistrate and deputy-lieutenant, and for a time acted as chairman of the Carnarvon bench. He was president of the North Wales branch of the British Medical Association, an hon. associate of the Order of St. John of Jerusalem in England, and a member of the Court of Governors of University College of North Wales. He was also a pioneer of the Volunteer movement, and for several years commanded the 6th Volunteer Battalion of the Royal Welch Fusiliers. During the war he had charge of military hospitals at Preston and Eaton Hall, and was afterwards medical commandant of the military hospital at Bangor until its disbandment. Colonel Roberts held the Volunteer long-service decoration and served in the Carnarvonshire Territorial Association. He leaves a widow, two sons, and two daughters.

## HENRY RAYNER, M.D. ABERD.

Henry Rayner was born in East Kent in 1841. After completing his school education he entered as a student at St. Thomas's Hospital and qualified as M.R.C.S. Eng. and L.S.A. Lond. in 1864. From London he went to Aberdeen, where he graduated M.B., C.M., with high academic honours in 1866 and took his M.D. in 1870. Soon afterwards he was appointed resident assistant physician at Bethlem Royal Hospital, and a year or two later became medical superintendent (male division) of the Hanwell Asylum, from which he retired about 1891 for consulting practice. He was for a time lecturer on mental diseases at Middlesex Hospital, but subsequently returned to his own hospital (St. Thomas's), where he was appointed physician for mental diseases (out-patient department). This was the first appointment of its kind in connexion with a London general hospital. Early in his career Dr. Rayner took an active part in the Medico-Psychological Association and was its honorary secretary; in 1884 he was elected president, and at the time of his death, therefore, he was the second senior past president of the now Royal Medico-Psychological Association, Sir James Crichton-Browne being the senior. Dr. Rayner was one of the promoters of the After-Care Association for the Insane discharged from asylums on recovery, and some years back succeeded the late Sir George Savage as its chairman, retaining the post until his death. This Association will miss him greatly, for its work was always near his heart. He was a ready writer, and contributed articles to Allbutt's "System of Medicine" and to the medical journals. For some years he was one of the editors of the *Journal of Mental Science*. As he was in his eighty-fifth year at the time of his death he had survived most of his contemporaries, but to the few of his old friends who remained he was endeared by his courteous and cultured manners, intellectual energy, and sympathy for his fellow men. Until a few days before his death he was active in mind and body.

Dr. Rayner leaves a widow, two sons who are members of the profession, and one daughter.

## MICHAEL FRANCIS COX, M.D. N.U.I.,

### PAST PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

AT the age of 75, Dr. Michael Cox died on Feb. 20th at his house in Merrion-square, Dublin, after a long illness. He was educated at the Catholic University School of Medicine, Dublin, and qualified in 1875. Twenty years later he became Fellow of the Royal College of Physicians and in 1923 was elected President. Unfortunately, he fell ill shortly after election and only performed the duties of the office for a short time. In 1895 the honorary degree of M.D. was conferred on him by the Royal University of Ireland, and during the Viceroyalty of Lord Aberdeen he was made a member of the Irish Privy Council, an honour which he resigned in 1920 to mark his disapproval of the Irish policy of Mr. Lloyd George's Government.

After a short period of country practice in Sligo in his younger days, Dr. Cox moved to Dublin, and became a member of the staff of St. Vincent's Hospital, to which institution he gave devoted service for the rest of his life. He was a hard-working physician and a careful and clear teacher; in consequence he enjoyed a large private and consulting practice. Apart from his medical work he had many interests; he was on intimate terms with all the Irish Nationalist leaders, was an indefatigable reader and book collector, and was a vice-president of the Royal Society of Antiquarians of Ireland. His academic appointments included membership of the Senate of the Royal University, and subsequently of the National University, and he was also Chairman of Convocation of the latter.

In his time there were few physicians in Ireland who were better known or enjoyed a larger practice. A man of strong convictions and deep feeling, Dr. Cox was courteous and tolerant to all, and was recognised as a man of great kindness and generosity.

## JOHN BENJAMIN STORY, M.B., M.CH. DUB.,

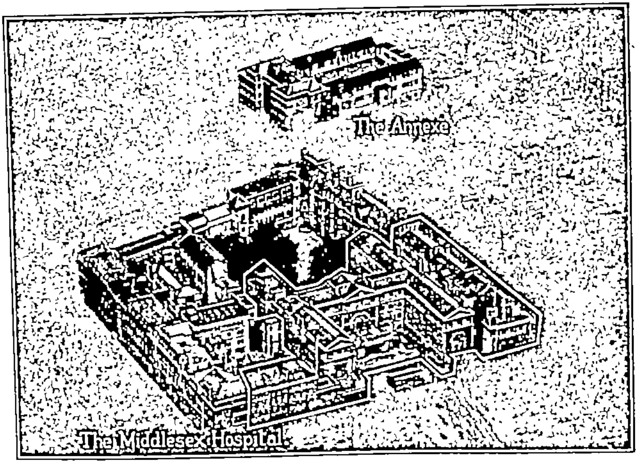
### PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE death of Mr. John Story occurred on Feb. 19th at Malahide, Co. Dublin, after a brief illness. He had retired from practice a few years ago and had reached the age of 75. Mr. Story was educated in Trinity College, Dublin, where he took an honours degree in arts in 1872 and his medical degrees in 1876. He subsequently studied at Zürich and Vienna, and then took up ophthalmic practice in Dublin. He became a Fellow of the Royal College of Surgeons in Ireland in 1880, was for many years a member of the Council, and was President from 1918 to 1920. He was for some time surgeon to St. Mark's Ophthalmic Hospital, and when it merged into the Royal Victoria Eye and Ear Hospital in 1896 he became surgeon to that institution, in which he continued to work until his retirement from practice. Mr. Story was president of the Irish Medical Association in the year 1913–14. In addition to his work as surgeon at the Royal Victoria Hospital, he was ophthalmic surgeon to Dr. Steevens' Hospital, and consulting ophthalmologist to Mercer's Hospital. He had a large practice in his specialty, and both for ability and character held a high place in the profession in Ireland.

# THE MIDDLESEX HOSPITAL ANNEXE.

## FORMAL OPENING.

On Feb. 23rd Mr. Neville Chamberlain, the Minister of Health, formally opened the temporary premises of the hospital in Cleveland-street. The building was once a Metropolitan Asylums Board infirmary and has been fully equipped from top to bottom according to modern standards of hospital design. There are six wards, two operating theatres, and an X ray department, and as the annexe is likely to be occupied for several years, during the reconstruction of the Middlesex Hospital, no pains have been spared to make it a self-contained unit of real efficiency. The transference of 98 patients over the distance of 250 yards from the condemned wards into the Cleveland-street annexe was successfully accomplished on Feb. 19th in less than three hours. The British Red Cross Society lent nine motor ambulances and the work was done by 30 students and the available staff of nurses. The aid of the police was needed to keep back the curious crowds that gathered in the neighbouring streets. The first patient was placed in an ambulance at 8.15 A.M. and the move was complete by 10.50—in ten minutes less than the time allowed. At the same time 14 patients were moved to another part of the main hospital.



View from the air showing the part of the Middlesex Hospital that is to be rebuilt (encircled by a white line) and the position of the Annexe.

Prince Arthur of Connaught, chairman of the hospital, formally welcomed Mr. Chamberlain, who, in a short address, touched lightly on many subjects of topical interest. He pointed out that the simplest, the easiest, and certainly the cheapest way of carrying on during the necessary reconstruction of the hospital would have been to refuse to accept any new patients until the numbers in the hospital had been so reduced that the old wards could be cleared for reconstruction. He had no doubt the Board must have considered such a course. But they regarded themselves as a unit in the great voluntary hospital system of London and they realised a responsibility towards the public. And so with great courage, but also with great wisdom, they took the opportunity to acquire an old building in close proximity to the hospital itself, and trusted to the public to see that the means were provided to carry out their plan. Moreover, they had not been content merely to provide a sort of clearing-house for their patients, but had visualised the ultimate conversion of the annexe into a new out-patient department which should be worthy of their importance in the hospital world. An out-patient department might not always seem as interesting or as important as an in-patient department, but it stood to the institutional work of the hospital in somewhat the same relation as prevention does to cure. It was in the out-patient department that the surgeon or the physician saw the first premonitory symptoms of disease, and it was there that often he was able to take such measures as might make it unnecessary for the patient even to visit the wards of the hospital.

The recent history of this hospital was a rather striking testimony to the vitality of that long threatened, but apparently unconquerable voluntary system. The three great functions of any general hospital were the provision of treatment for accident and for disease, the training of future practitioners, and the pursuit of research. It was a significant fact that every teaching hospital in this country was on the voluntary principle and that the voluntary hospitals were not only the pioneers of medical research, but are still actively developing the research side of their activities. The voluntary system had admitted defects and gaps and it was not altogether unnatural that some people should protest against the uncertainties of a scheme which depended entirely upon the voluntary offerings of a generous public, and plead that it should be turned over to the State, and to the boundlessness and unfailing resources of the Chancellor of the Exchequer. Were we certain, however, that they are unfailing? It would not be very long before we were all made aware of the state of the national purse, and then we should know whether we could afford to despise these voluntary sacrifices, which, to the givers, formed a source of satisfaction, in that they were giving of their own free-will what they would only yield to compulsion with reluctance and perhaps even with resentment.

In Mr. Chamberlain's opinion, destruction of the voluntary system would be a national disaster of the first magnitude. It might be that some day the health services would be so developed as to come nearer to the ideal plan under which there should be no unnecessary duplication, no waste, no overlapping, and yet which should offer to every citizen not merely the highest professional skill, but the use of all that wonderful apparatus and equipment which modern science had put at our disposal. Even to get an approximation to such an ideal meant that every agency now working for the prevention or the cure of disease would have to be coördinated. It might be that, if an adequate place was to be found in such a scheme for voluntary hospitals, it would be necessary to bring about some changes in their relations with other institutions, to ask them to yield up something of the complete independence they enjoyed to-day. But if such a change should ever come about he expressed conviction that the change must be so contrived that they should not in any way impair or injure those great qualities which had made our voluntary hospitals the pride of this country.

# INTRATHORACIC NEW GROWTHS.

## A MANY-SIDED DISCUSSION.

At a combined meeting of several Sections of the Royal Society of Medicine—Medicine, Electro-Therapeutics, Surgery, and Laryngology—held on Feb. 23rd, the chair being occupied by Dr. Hugh Thursfield, the President of the first-named Section, a discussion on Intrathoracic New Growths was introduced, from the medical aspect, by Dr. L. S. T. Burrell, whose paper appears in full on p. 435.

### *The Laryngological Aspect.*

Mr. Somerville Hastings, speaking as a laryngologist, said that intrathoracic new growths made themselves known (1) by laryngeal symptoms due to pressure on the vagus and its branches, (2) by pressure on or involvement of the œsophagus, (3) by obstructing the lumen of the trachea or bronchi. Involvement of the pneumogastric nerve might cause paroxysms of coughing. The exact results laid down in Semon's law occurred, the abductor fibres going first and being followed by the adductor. When both recurrent nerves were involved, or one or both was in the first stage of pressure, there might be considerable dyspnœa and noisy inspiration. When an intrathoracic tumour was malignant and when complete paralysis of both cords was certain, should the patient live long enough, he considered that intubation was preferable to tracheotomy, for it would tide the patient over until the stage was reached of complete cord paralysis in the cadaveric position. A mediastinal tumour might first become evident by pressing on the œsophagus and causing difficulty in swallowing. In most cases of œsophageal obstruction more accurate information was obtainable by passing the œsophagoscope than by taking skiagrams after an opaque meal; especially was this so when a mediastinal tumour was present. To relieve the obstruction the passage of a Symonds's or a Souttar's tube might be necessary, or well-screened radium could be applied to the growth from the œsophagus. Rarely was gastrostomy required. Examination of the main bronchi could well be carried out by means of the bronchoscope, while with the use of that instrument bismuth subcarbonate or lipiodol could be carried out, and the condition rendered clear to the X rays. As a result of obstruction of bronchi by new growth bronchiectatic dilatations often occurred, and lung abscesses, with foul breath, might follow. In such a condition the comfort of the patient, and therefore of his friends also, was much increased by performing lavage through the bronchoscope.

### *The Surgical Aspect.*

Mr. J. E. H. Roberts gave his extensive experience of dealing surgically with the kind of growths under discussion. He reminded the meeting of the saying of Dr. Finney, of Baltimore, that in regard to intestinal obstruction it was more important to operate early than to operate well. There was not the same urgency about intrathoracic tumours, but until diagnosis was made earlier treatment for malignant tumours would be merely palliative, and even in innocent tumour cases the treatment would continue to be more difficult and risky than it need be. The clinician still regarded chest tumours as rare events, hence when they occurred they were often unsuspected; but it was hoped that a result of this discussion would be that physicians would be on the look-out for the early signs and symptoms of carcinoma of the bronchi and of the lung, and diagnosis by various methods arrived at, such as by X ray examination with various aids, bronchoscopy, thoracoscopy, blood examinations, complement-fixation, &c. He confined his remarks to neoplasms. Innocent neoplasms were rarer than malignant ones, but now that the chest was being so frequently X rayed these were being found in larger numbers. The commonest innocent tumours in this region were dermoid cysts and fibromata, the dermoid cysts being generally in the anterior mediastinum. As a general principle Mr. Roberts said that if an innocent tumour in the chest was discovered before any symptoms arose from it it should be removed at that stage, as operative risks were then at a minimum. The two main modes of access to these growths were: (1) transpleurally, by a long intercostal incision; (2) by a sternum-splitting operation. A smoother convalescence followed the second method in tumours which filled the apex of the chest, and the first method for those of the middle and lower parts of the chest.

Concerning the primary sarcomata of the lung or mediastinum, these were best treated by X rays or by the implantation of radium. Final cure was not to be expected. Primary carcinoma of the lung seemed to have become more frequent in the last ten years, and it was met with in two main forms: (1) the commoner one commencing in the bronchus; (2) the rarer, starting in the parenchyma. In either case there was constriction of the lumen of a bronchus followed, at first with the absorption of the air beyond, retention of secretions, later on by bronchiectasis, lung abscess, and empyema. If such a patient were seen before infection it should be possible, from the altered breath sounds and percussion note, to suspect bronchial blockage and to discover its cause by bronchoscopy. Experimental work had shown that resection of uninfected lobes of lung could be carried out without great mortality, but when gross infection was added the mortality of that operation was very high. Parenchymatous growths were more amenable to surgery. The palliative treatment of carcinoma of the lung consisted in drainage of pulmonary abscesses and of secondary empyemata, bronchostomy to drain dilated bronchi, &c. The comfort to the patient rendered these procedures well worth while.

### *The Radiological Aspect.*

Dr. Stanley Melville gave an historical sketch of the progress of skiagraphy, and described the general contours and appearances of thoracic growths as he had met with them. Most of his contribution consisted of a demonstration of differential features as seen in the X ray plates, and the best methods of bringing out the diagnostic features.

Dr. Robert Knox also demonstrated a series of skiagrams with the same object, his chief purpose being to insist on the supreme importance of making a diagnosis before any attempt was made at treatment. He said that during the last year he had had six cases of aneurysm of the aorta sent to him for treatment under the impression that they were examples of malignant neoplasm; possibly on occasion he had treated with rays an aneurysm as a neoplasm. He showed skiagrams at different stages illustrating the value of X rays in causing the disappearance of such tumours as lymphosarcoma, and insisted that there was no need to carry out surgery in such cases in order to insert radium, as the curative effect of the rays was very remarkable. In some long-standing cases it was evident that the natural resistances of the body had become exhausted and no effort could be put forward by the patient to respond to the treatment.

### *Discussion.*

Dr. Hilton urged the induction of an artificial pneumothorax in order to facilitate not only the clarity of X ray pictures, but also surgery should that be necessary, as surgeons had remarked on the greater ease of operation on a collapsed lung. The air in the lung need only be slightly different from the normal, either at or just below the atmospheric pressure.

Sir John Briscoe demonstrated by means of the epidiascope the signs by which paralysis of one phrenic nerve could be definitely diagnosed. He said that in the last three years he had correctly diagnosed the condition in 41 cases. Of these cases 22 were primary growths in the thorax, 10 secondary, 6 due to syphilis (including aneurysm), and 3 to tubercle. The phrenic nerve on the right side was involved in 31 instances, on the left in 13, on both in 3. He insisted on the importance of examining these patients in a very quiet condition, and refraining from asking them to take a deep breath.

Dr. F. G. Chandler spoke on differential diagnosis and treatment. He urged early diagnosis of intrathoracic tumours, as it was only at that stage that hopeful surgery could be expected.

Dr. Devereux Forrest gave a detailed and analytical account of an investigation he had conducted in 152 post-mortem examinations in cases of carcinoma of the lung at the London Hospital from 1907 to 1925. All the cases were certified by Prof. Turnbull at the hospital as carcinoma. He had been unable to associate any particular occupation with the occurrence of these growths, the only notable point in this regard being that no agricultural labourer was in the list.

The President (Dr. Thursfield) combated the idea expressed by several speakers that these intrathoracic new growths were becoming more common. This appeared to have been founded on the increased number of such cases seen at the hospitals, but it must be remembered that the total admissions to London hospitals was nearly double in 1925 that of 1907, and patients passed through the hospitals more rapidly. Also considerable classes of cases had been removed from the wards of general hospitals, particularly tuberculous cases. Desperate carcinomata and other cases of the kind were now freely admitted, whereas within his own memory that was not the case. He did not believe the apparent increase in the kind of cases under discussion was a real one.

Mr. T. P. Dunhill submitted that the diagnosis of intrathoracic new growths from other conditions, even by the use of all the means now available, was often a very difficult matter. He showed skiagrams of three particular cases and pointed the lessons.

Dr. Willis said it seemed to be clear that, if looked for, these new growths in the thorax were not much less common than were malignant growths in other organs. He devoted special attention to the clinical aspect, as that was the one in which the disease first presented itself, and a study of the cases at this stage would result in their being recognised at the period when they could hopefully be operated upon. The symptoms fell into three groups according to the situation of the tumour, and these he fully entered into, describing cases in illustration.

The President, summing up the discussion, expressed his surprise that more had not been said about the early occurrence of dyspnœa in these cases. Often patients did not volunteer a complaint of dyspnœa, but a leading question mostly elicited it, and even when so gleaned he regarded it as a sign of more value than seemed to have been accorded to it by most of those who had spoken. A second point was that stressed by Sir John Briscoe—namely, the importance of the physician actually seeing the screening of the case; he should not be merely content with seeing the X ray plate, especially as in that case he was dependent on the radiographer's interpretation of it. This was of special importance when the case was one possessing a large element of doubt, for by means of the fluorescent screen various positions could be taken up and the whole case viewed critically.

Mr. Roberts, in reply, agreed with Dr. Hilton as to the advantage to the surgeon of the induction of a preliminary artificial pneumothorax, as well as its value in diagnosis. He had seen large external veins on the chest in innocent tumour cases, but not very large veins. He agreed that every diagnostic aid should be utilised in the case of these difficult tumours. If in the case of innocent tumours X ray pictures were taken at intervals to learn whether increase in growth had occurred, the same distance and other details should be observed every time. Otherwise a false impression might be derived.

Dr. Melville, in reply to Dr. Forrest, said he thought all clinicians were now agreed that one of the striking and constant features of intrathoracic new growths was displacement of the heart to the side of the lesion. With regard to the President's remark concerning the screen examination by the physician himself, radiologists as a body would welcome this intrusion into what was still too much the water-tight compartment of their specialty. Everything should be done to bring the physician and the radiologist into closer working relationship.

# Medical News.

University of Oxford.—At a recent Congregation the degrees of B.M., B.Ch. were conferred on R. G. Mathews (Queen's College) and D. O. Williams (Jesus College).

Society of Apothecaries of London.—At recent examinations the following candidates passed in the subjects indicated:—

*Surgery.*—J. Dywien, Guy's Hosp.; M. Escovar, Cambridge and London Hosp., A. C. Hill, Liverpool; J. E. Howard, St. Mary's Hosp.; J. Mindess, London Hosp.; L. A. Rostant, St. Thomas's Hosp., J. Shibko, Cardiff; and V. R. Smith, Manchester.

*Medicine.*—G. H. Bickmore, Charing Cross Hosp.; T. K. Clifford, Manchester; E. W. Hayward, Cambridge and London Hosp.; W. Johnson, St. Mary's Hosp.; J. M. Moran, Manchester; C. E. Nicholas, London Hosp.; I. Rivlin and G. H Weeber, Middlesex Hosp.; and J. M. F. Whitby, St. Thomas's Hosp.

*Forensic Medicine.*—C. B. Ball, Sheffield; T. K. Clifford, Manchester; E. W. Hayward, Cambridge and London Hosp.; C. H. St Johnston, Birmingham; G. H. Pereira, St. George's Hosp.; J. Shibko, Cardiff; and J. W. Whitney, London Hosp.

*Midwifery.*—N. H. C. Allen, Guy's Hosp.; F. W. Barton, Middlesex Hosp.; V. G. Crowley, Sydney and St. George's Hosp.; M. Escovar, Cambridge and London Hosp.; H. I. Jones, St. Mary's Hosp.; D. P. Mitra, Charing Cross Hosp.; and G. H. Pereira, St. George's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: T. K. Clifford, V. G. Crowley, E. W. Hayward, J. Mindess, G. H. Pereira, and L. A. Rostant.

London School of Hygiene and Tropical Medicine.—In the recent sessional examination of the division of tropical medicine and hygiene the winner of the Duncan Medal was Mr. R. M. Morris, late house physician at the London Hospital.

University of Bristol.—At examinations held recently, the following candidates were successful:—

Examination for Degree of Ch.M. (in Gynæcology).
*Harry L. Shepherd.*

Final Examination for Degrees of M.B., Ch.B.

*Part I.*—John C. Batt, Winifred P. Brinckman, Alan M. Critchley, *Thomas F. Hewer, Reginald Jackson, John E. Martin, John R. E. Sansom, Maiprom Srisvasti, *Dorothy M. H. Tripp, and Edgar R. Wide.

* Distinction in Materia Medica, Pharmacy, Pharmacology and Therapeutics.

*Part II.—Second-class Honours.*—Charles B. Perry (distinction in Obstetrics).

*Pass.*—Geoffrey W. R. Bishop, Robert V. Cooke, Francis S. Dymond, Francis R. Gedye (distinction in Pathology and Forensic Medicine and Toxicology), Arthur P. Corham, Thomas P. Lalonde, Gilbert M. Minifie, Leslie B. Phillips, and Arthur S. Prowse.

*Group II only.*—George L. Feneley and Cecily France-Hayhurst.

The degree of M.D. has been conferred on Elizabeth Casson.

Ideal Home Exhibition.—The tenth *Daily Mail* Ideal Home Exhibition will be held at Olympia, London, from March 2nd to 27th. There will be sections devoted to the lighting, heating, and ventilation of houses.

Fellowship of Medicine and Post-Graduate Medical Association.—On March 4th, at 5 P.M., a lecture on Dyspepsia will be given by Dr. E. P. Poulton in the lecture room of the Medical Society, at 11, Chandos-street, London, W. This lecture is free to all members of the medical profession. Beginning on March 1st, there will be a special series of demonstrations on the Diagnosis and Treatment of Diseases of the Eye at the Royal Eye Hospital, St. George's Circus, Southwark. These demonstrations will be given by members of the staff and will take place at 3 P.M. daily for a fortnight. On Tuesdays and Thursdays throughout the month there will be a special course in bacteriology at the Westminster Hospital, and a two-hour session will be held on each of these days. On March 8th, and for the next three weeks, the Chelsea Hospital for Women will hold a special course in gynæcology. Operations, demonstrations, and lectures will take place daily. From March 13th to 27th the Brompton Hospital will hold an all-day course in Diseases of the Chest, and on the 16th the London School of Tropical Medicine will begin a series of eight clinical demonstrations, extending over four consecutive weeks, on Tuesdays and Thursdays at 2 P.M. For the benefit of those who are unable to devote the whole day to study, the Hampstead General Hospital is holding a special post-graduate course for practitioners from March 15th to 20th. The daily sessions will be held from 1.30 to 6 P.M., and will include clinical and surgical demonstrations and lectures. Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

UNIVERSITY OF LONDON.—Applications for grants from the Thomas Smythe Hughes Medical Research Fund, which are allocated annually for the purpose of assisting original medical research, should be sent in not earlier than May 1st and not later than June 15th. Particulars may be obtained from the Academic Registrar.—A studentship in physiology, of the value of £50 for one year and tenable in a laboratory or school of the University, will be awarded to a student or graduate annually. Applications must be received by the Principal Officer on or before May 31st.

INTERNATIONAL PHYSIOLOGICAL CONGRESS.—The twelfth congress is to be held at Stockholm from August 3rd to 6th. Those who wish to be enrolled as members should forward their names and addresses, together with the amount of their subscription (20 Swedish crowns), to Dr. G. Liljestrand, Karolinska Institutet, Stockholm. Further particulars will be given later.

PEOPLE'S LEAGUE OF HEALTH.—The League has arranged a series of six lectures on Diet: What We Should Eat and Why, to be delivered in the lecture-room of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, beginning on Wednesday, March 10th, at 6 P.M. The following is a list of lecturers and subjects: Dr. Leonard Hill, F.R.S., The Nature and Purpose of Food; Prof. R. H. A. Plimmer, Vitamins; Dr. M. J. Rowlands, Diet in Relation to Tuberculosis and Rheumatism; Prof. W. Cullis, Food in Relation to Growth; Prof. V. H. Mottram, Common Errors in Diet; Prof. W. E. Dixon, F.R.S., Food Preservation and Adulteration.

*Lectures in Prisons and Borstal Institutions.*—The second series of the Sims Woodhead Elementary Course of Constructional Health Lectures has just been concluded by the People's League of Health at Wandsworth Prison and Borstal Institution, Rochester. The course was followed by a written examination, and certificates and prizes will be awarded to those who have gained the highest number of marks. This course has also been given at the Borstal institutions at Feltham and Aylesbury.

LEAGUE OF NATIONS AND MALARIA.—The health organisation of the League has arranged to hold next summer in London, Paris, and Hamburg, special laboratory courses on malaria. These will be reserved for medical officers. During its tours of Eastern and Southern Europe, the League's Malaria Commission was impressed by the fact that a number of countries were prevented from carrying on systematic antimalarial campaigns owing to the shortage of specially trained physicians. The health organisation, therefore, has decided to organise courses in malariology for young physicians desiring to specialise in this subject in order to become members of their public health administrations. The health committee has secured the collaboration of Dr. Andrew Balfour, director of the London School of Hygiene and Tropical Medicine, who will hold a theoretical and laboratory course in London, details of which may be obtained from the health section of the secretariat of the League of Nations at Geneva. Field work, lasting several months, in such malaria-infected countries as Corsica, Italy, Spain, Jugo-Slavia, and possibly Palestine, will follow the theoretical stage of the course.

INTERNATIONAL SOCIETY OF SURGERY. — As announced in our issue of Feb. 13th, the seventh congress will be held in Rome from April 7th to 10th. Prof. Giordano, of Venice, will be the President, and the subjects for discussion are: (1) Radium Treatment of Uterine Cancer. Speakers: Dr. O. Beuttner (Geneva), Dr. M. Donaldson and Dr. S. Forsdike (London), Dr. E. Pestolozza (Rome), Dr. G. Recasens (Madrid), and Dr. Regaud (Paris). (2) Abscess of the Liver: Dr. J. Domenici (Rome) and Dr. Petridis (Alexandria). (3) Treatment of Cerebral Tumours: Dr. A. W. Adson (Mayo Clinic), Dr. Bastianelli (Rome), Dr. de Martel (Paris), Mr. Percy Sargent (London), Dr. Brun (Lucerne), and Dr. M. Lozano (Saragossa). (4) Surgery of the Spleen: Dr. Cortes-Llado (Seville), Dr. Henschen (St. Gall), Dr. Leotta (Bari), Dr. Papayoannou (Ghezireh), and Dr. Patel (Lyons). (5) Late Results of Jacksonian Epilepsy: Dr. Leriche (Strasburg). Operations will be performed in the hospitals on two mornings. Two tours have been arranged in connexion with the congress: (1) A tour to Milan, Venice, Padua, Bologna, and Florence, starting from London on March 29th and arriving in Rome for the commencement of the congress. (2) A tour to Naples, Pompeii, Vesuvius, and the Isle of Capri, from April 13th to 16th. Messrs. Thos. Cook and Son, Ltd., have been appointed official agents and will quote inclusive fares based on the reductions granted by the Italian State railways to members of the congress, who may be accompanied by their wives and families. Further particulars may be obtained from the British delegate, Mr. J. E. H. Roberts, 26, Harley-street, London, W. 1.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The Morison lectures will be delivered on March 1st, 3rd, and 5th, by Dr. R. D. Clarkson, in the hall of the College, at 5 P.M. The subjects of the three lectures will be the Definition of Mental Deficiency and the Classification of Mental Defectives; the Causes of Mental Deficiency; and the Treatment of Mental Defectives.

HEALTH LECTURES AT WILLESDEN.—Under the auspices of the Willesden Urban District Council a series of lectures on health will be given during March. The first, entitled the Foundations of Public Health, will be given at Pound-lane Council School, Willesden, N.W., on Thursday, March 4th, at 8 P.M., by Sir George Newman. On the three following Thursdays, at the same hour, there will be lectures by Dr. C. S. Thomson, Dr. H. B. Brackenbury, and Dr. C. W. Saleeby.

INSTITUTE OF HYGIENE.—A series of lectures on the Health of the Child of School Age is being given at 28, Portland-place, London, W., on Wednesdays, at 3.30 P.M. All interested in health problems may attend. On March 3rd Dr. Soltau Fenwick will speak on Disorders of the Digestive Organs during School Life; on March 10th Dr. C. E. Shelley will speak on the Incidence of Infectious Diseases in Public Schools; on March 17th Dr. R. Scott Stevenson will deal with Affections of the Ear, Nose, and Throat and their Prevention; and on March 24th Lieut.-Colonel R. H. Elliot will discuss Eye Troubles of School Life.

A STUDENTS' BED AT BIRMINGHAM.—The fourth bed endowed at the Queen's Hospital by the Birmingham University students has been dedicated by the Lord Mayor. The cost, £1250, was allocated from the proceeds of the students' carnival held last October, together with a further sum of £600 given to the general funds. These carnivals have been the means of contributing a total of £6800 to the hospital.

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW. At a recent meeting at which the President, Prof. Archibald Young, took the chair, Mr. George Dalziel showed three cases of trigeminal neuralgia which had responded satisfactorily to injections of alcohol into the third branch of the fifth nerve. Mr. James Learmonth read a paper on Neuralgias of the Head and their Treatment, in which he recommended earlier resort to operation in trigeminal neuralgia. The best procedure was division of the sensory root of the fifth nerve between the ganglion and the pons, which gave instant and permanent relief at the cost of permanent anæsthesia over the distribution of the nerve. The technique he employed was that of Dr. A. W. Adson, neurological surgeon to the Mayo Clinic.

ORTHOPÆDIC HOSPITAL OF IRELAND.—The Incorporated Orthopædic Hospital of Ireland has now entered its jubilee year. The hospital was founded in 1876, mainly by the efforts of the late Mr. R. L. Swan. At first it consisted of six beds in Mr. Swan's own house at Usher's Island, Dublin. Seven years later it moved to Great Brunswick-street, where 48 beds were available. In 1902 it moved to its present site in Upper Merrion-street, and it has now 80 beds. During the 50 years of the life of the hospital some 30,000 children have been treated. Last year no less than 1576 children were treated. From the foundation of the hospital up to his death in 1916 Mr. Swan was surgeon to the hospital, and was its guiding and active spirit. To his surgery and foresight the crippled children of Ireland owe much.

LONDON CLINICAL SOCIETY.—The inaugural meeting of this society was held at the London Temperance Hospital, Hampstead-road, on Feb. 18th, Mr. H. J. Paterson, the president, in the chair. In his opening remarks the President said that the object of the society was to interest practitioners of the neighbourhood in the work of the Temperance Hospital, by offering them the opportunity of discussing cases of clinical interest in its wards. The chief guests of the evening were Sir StClair Thomson, who wished the society every success, and Sir Arbuthnot Lane, who gave an interesting discourse on the question: Is Civilisation a Failure? The answer, he considered, was in the affirmative. Savage races which had lived in happiness and health for hundreds of centuries degenerated and decayed as soon as civilisation touched them. The failure of civilisation lay in an alteration of the simple mechanical relationship Nature intended us to maintain towards our surroundings. This has caused alterations in human anatomy which had produced all the ills from which we suffered to-day. The lecture was illustrated by lantern slides. The first clinical evening of the society will be held on March 18th, when cases and specimens will be shown. Particulars of membership may be obtained from the Secretary, Dr. Philip Figdor, 150, Harley-street, W. 1.

OVERSEAS MEDICAL OFFICERS.—The annual reunion dinner of the Overseas Medical Officers will be held at the Exchange Hotel, Liverpool, on Thursday, March 4th, at 7.30 P.M. Tickets, price 12*s.* 6*d.*, may be obtained from Dr. J. W. Burns, 40, Rodney-street, Liverpool.

ABERDEEN ROYAL INFIRMARY.—For the first time for at least half a century this hospital has paid its way, and has, moreover, added £15,000 to its capital, notwithstanding that last year it treated a larger number of patients than ever before. Very soon, however, extensive additions will have to be made to the buildings. Workmen's contributions have now reached nearly £4000, and patients' contributions amounted to £2000.

COST OF THE SMOKE EVIL.—At a meeting of the Circle of Scientific, Technical, and Trade Journalists held in London on Feb. 10th, Dr. John S. Owens, of the Meteorological Office, said that the cost arising either directly or indirectly from smoke approximated in the case of London to 21*s.* per head per annum, in Manchester to 30*s.* per head, and in Pittsburg to 87*s.* per head. In London the cost was £7,000,000 a year, all of which could be saved if smoke was done away with. The cost to the whole country was colossal. All this was preventable, and the engineer was quite capable of dealing with the problems if only there was a strong public demand for a solution.

A MOSQUITO BITE CLAIM UNDER COMPENSATION ACT.—An unusual compensation action was heard recently at the Manchester County Court before Judge T. B. Leigh. The applicant was Mrs. Nora Robinson, of Ancoats, Manchester, a widow, who applied under the Workmen's Compensation Act in respect of the death of her husband, who had been employed as a donkeyman on board the ship *Tringa*, owned by the respondents, the British and Continental Steamship Company, Limited, of Liverpool. The fact that Robinson was bitten by a mosquito when the vessel was at Ghent on August 5th and died 13 days thereafter, when the vessel arrived in the Manchester Ship Canal, from septicæmia and pyæmia following cellulitis, was not disputed. The judge said that the *Tringa* at Ghent was unloading 300 or 400 yards from marshy land, which was the breeding-ground for mosquitoes. The lights of the ship were brighter than those on shore, and he was satisfied there was a greater danger of being bitten on board than there was in the town, where certain preventive precautions were taken. Robinson had to attend to two furnaces and was bound to have an unshaded electric light in order to do his work properly. The heat and light of the boiler house attracted mosquitoes, while Robinson had a smaller chance of avoiding their attacks than he would have had if he had not been at work. The judge held that the mosquito bite was an accident within the meaning of the Compensation Act and gave his award in favour of the applicant in the agreed sum of £334 with costs. Counsel for the respondents said he would like time to consider the position, and at his request a stay of execution was granted upon payment of the money into court within seven days.

CLINICS FOR RHEUMATIC PATIENTS.—At a conference of delegates of the Provincial Centre of the National Association of Trade Union Approved Societies held in Manchester on Feb. 16th, Mr. W. A. Appleton, secretary of the General Federation of Trade Unions, gave an address on the Incidence and Cost of Rheumatism. He said that an analysis of the medical certificates received at the office of the General Federation of Trade Unions showed that from 9 to 10 per cent. of the invalidity arose from rheumatic causes, and that 370,000 insured persons each year sought advice for some form of rheumatic disease or consequence thereof. Spas were available for the treatment of the rich. What was good for them might be equally good for the poor, but the existing capacity of the spas, allowing for an average 21 days per case for treatment, was not more than 12,000 persons per year. Clinics were needed for the benefit of those not likely to benefit by spa treatment—for experiment, for advice, and for the encouragement of those who might be treated in their own homes or by themselves. The cost of installation and maintenance of such clinics would be considerable. The Ministry of Health might agree to contributions on a pro-rata basis for the creation of several experimental clinics. A better, because a freer, way would be to secure several clinics by voluntary effort, and it ought not to be impossible to persuade every one of the million members of the Trade Union Federation of Approved Societies to raise sixpence to provide and equip a clinic in London and one in Manchester. Mr. Appleton suggested that the Federation should coöperate in the effort and in ascertaining from the Ministry of Health how far it would encourage collaboration for experimental purposes. One-seventh of the total sickness benefit, or nearly £2,000,000 a year, was paid to the insured population for invalidity from this disease.

# Parliamentary Intelligence.

## HOUSE OF COMMONS.

### WEDNESDAY, FEB. 17TH.

### *Tuberculosis in the Navy.*

Captain FAIRFAX asked the First Lord of the Admiralty whether the latest figures available showed any decrease of tuberculosis in the Navy; and whether he was satisfied that all reasonable precautions were enforced to prevent the spread of this disease.—Mr. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: The ratio per 1000 invalided during the last four years was: 1922, 1·06; 1923, 1·01; 1924, 1·57; and 1925, 2·20. The answer to the second part of the question is in the affirmative.

### *Families Living in One and Two Rooms.*

Mr. THURTLE asked the Minister of Health if he had any figures in his department showing the number of persons living in England and Wales in homes of one room; and the number living in homes of two rooms.—Sir K. WOOD replied: According to the Census of 1921 there were in England and Wales 317,417 private families consisting of 623,800 persons occupying one room per family, and 917,058 private families, consisting of 2,831,802 persons, occupying two rooms per family.

### *Maternal Mortality.*

Mr. GROVES asked the Minister of Health the number of mothers who lost their lives from causes due to childbearing in England and Wales during 1923 and 1924; and the ratio of such deaths to the total births during the year.—Sir K. WOOD (Parliamentary Secretary to the Ministry of Health) replied: The following statement gives the number of deaths from these causes in 1923 and 1924 and the mortality rates per 1000 births registered:—

| — | 1923. | | 1924 | |
|---|---|---|---|---|
| | No. | Rate.* | No. | Rate.* |
| Deaths of women classed to pregnancy and childbearing | 2892 | 3·81 | 2847 | 3·90 |
| Deaths of women not classed to pregnancy and childbearing, but returned as associated therewith .. | 764 | 1·01 | 851 | 1·17 |
| Total .. .. .. | 3656 | 4·82 | 3698 | 5·07 |

* Mortality rate per 1000 births registered.

The number of births in England and Wales was 758,131 in 1923, and 729,923 in 1924.

Mr. GROVES asked the Minister of Health what improvement, if any, was manifest respecting the maternal mortality in rural, textile, and coal-mining areas; and whether it was the custom for all medical officers of health to investigate all maternal deaths due to childbirth, and all cases of puerperal fever whether fatal or not.—Sir K. WOOD replied: On present information my right hon. friend is unable to say that there has as yet been any general improvement in the maternal mortality rate in these areas, but the figures for 1925 are not yet available. As regards the second part of the question, the Circular issued by my right hon. friend's department in June, 1924, on the subject of maternal mortality impressed upon local authorities conducting maternity and child welfare schemes the desirability of competent medical investigation into all the maternal deaths and all cases of puerperal fever. The extent to which this practice is adopted varies in different areas.

### *Medical Examination at Labour Exchange.*

Mr. NEIL MACLEAN asked the Minister of Labour whether he was aware that a number of women who were signing at the Govan labour exchange had been called upon to undergo a medical examination by medical doctors at the exchange; whether he could state the reasons for this course and its purpose; whether the medical examination was compulsory on those called to undergo it; if not, whether women so called upon could refuse without prejudice to their claims for benefit; and under which statute these powers were operated by his department.—Sir A. STEEL-MAITLAND replied: I presume the hon. Member refers to a test which is being carried out with my consent by the Industrial Research Fatigue Board. Acceptance of the test, which is carried out by a woman doctor and a woman assistant, is absolutely voluntary and does not affect benefit in any way. The proposal of the Board was considered by a conference of women representatives of local employment committees in Glasgow who considered that it would be useful.

**Mr. Maclean**: Are we to take it that women who are going to the exchanges are told that they are to be examined by a lady doctor without it being explained that it is voluntary, and are they led to assume that if they do not undergo this medical examination their claim to benefit will be prejudiced and probably disallowed; and further, will the right hon. gentleman have this practice discontinued?

Sir A. **Steel-Maitland**: The hon. Member must not draw the inference that women are led to undergo any examination without being told that it is voluntary on their part. I will undertake to see that it shall be made quite clear that the examination is entirely voluntary and unconnected with benefit. On the other hand, inquiries by the Research Board are for the general good, and I should be very sorry to stop them.

### THURSDAY, FEB. 18TH.

### *Diseases Scheduled for Workmen's Compensation.*

Mr. **Jenkins** asked the Home Secretary the description of diseases under the Workmen's Compensation Acts Orders which had been scheduled by his department up to date.—Sir W. **Joynson-Hicks** replied: An up-to-date list of the scheduled diseases with their full descriptions will be found in Appendix II. of the Home Office Memorandum on the Acts which is printed and on sale. Over 30 diseases have been scheduled. In addition to the diseases scheduled under the general provisions of the Act of 1906 silicosis in certain industries has been dealt with under the special provisions of the Workmen's Compensation (Silicosis) Acts.

### *Physical Impairment of Rural Children.*

Mr. **Scurr** asked the President of the Board of Education whether his attention had been drawn to the report of the chief medical officer of the Board as to the deterioration in the physical standard of children in rural areas; and whether, in view of the effects on the nation, he proposed to take any action in the matter.—The **Duchess** of **Atholl** (Parliamentary Secretary to the Board of Education) replied: The report in question, while stating that there was a substantial degree of physical impairment among rural children, added that there were good grounds for believing that on the whole there was improvement, and in some rural areas great improvement. The remedy lies in the main along the lines on which the Board and local authorities have been steadily working in the past, and what is needed is perseverance on these lines, especially in regard to the replacement of unhealthy school buildings, rather than any new departure of policy. As regards the chief medical officer's recommendstion that children under 6 years of age in rural areas should be discouraged from attendance at school in certain circumstances, my right hon. friend is considering whether there is any advice which he can usefully tender to local authorities on this point.

### *Small-pox and Vaccination.*

Major **MacAndrew** asked the Minister of Health whether, in view of the spread of small-pox, he intended to resort to the more widespread use of vaccination.—Mr. N. **Chamberlain** replied: In areas invaded by small-pox it is the usual practice for the local authorities to urge the importance of vaccination and to announce the facilities for vaccination free of cost to all who desire it, but there is no statutory provision for compulsory vaccination, except in the case of children whose parents have not made declarations of conscientious objection to vaccination.

### *The General Medical Council.*

Mr. **Storry Deans** asked the Minister of Health whether he had considered the suggestion that the General Medical Council ought to contain a lay element; and, if so, having regard to the power of nomination conferred on the Crown by the Medical Act, 1886, he would take steps to secure that this power should be exercised by the appointment of laymen as and when vacancies arise.—Mr. N. **Chamberlain** replied: Yes, Sir, I have considered my hon. friend's suggestion and I will take an early opportunity of consulting the Lord President on the matter.

### *Milk and Dairies Order.*

Mr. **Robert Morrison** asked the Minister of Health if he was yet in a position to state when the draft orders made by him under Section 1 of the Milk and Dairies Act, 1915, would be published.—Mr. N. **Chamberlain** replied: I hope to publish the draft order in question in the course of a few weeks.

### *Tuberculosis in the Navy.*
